A Complexity Trichotomy for Approximately Counting List $H$-Colorings

ANDREAS GALANIS and LESLIE ANN GOLDBERG, University of Oxford
MARK JERRUM, Queen Mary, University of London

We examine the computational complexity of approximately counting the list $H$-colorings of a graph. We discover a natural graph-theoretic trichotomy based on the structure of the graph $H$. If $H$ is an irreflexive bipartite graph or a reflexive complete graph, then counting list $H$-colorings is trivially in polynomial time. Otherwise, if $H$ is an irreflexive bipartite permutation graph or a reflexive proper interval graph, then approximately counting list $H$-colorings is equivalent to #BIS, the problem of approximately counting independent sets in a bipartite graph. This is a well-studied problem that is believed to be of intermediate complexity—it is believed that it does not have an FPRAS, but that it is not as difficult as approximating the most difficult counting problems in #P. For every other graph $H$, approximately counting list $H$-colorings is complete for #P with respect to approximation-preserving reductions (so there is no FPRAS unless NP = RP). Two pleasing features of the trichotomy are (1) it has a natural formulation in terms of hereditary graph classes, and (2) the proof is largely self-contained and does not require any universal algebra (unlike similar dichotomies in the weighted case). We are able to extend the hardness results to the bounded-degree setting, showing that all hardness results apply to input graphs with maximum degree at most 6.

1. OVERVIEW

In this article, we study the complexity of approximately counting the list $H$-colorings of a graph. List $H$-colorings generalize $H$-colorings in the same way that list colorings generalize proper vertex colorings. Fix an undirected graph $H$, which may have loops but not parallel edges. Given a graph $G$, an $H$-coloring of $G$ is a homomorphism from $G$ to $H$—that is, a mapping $\sigma : V(G) \rightarrow V(H)$ such that, for all $u, v \in V(G)$, $\{u, v\} \in E(G)$.

These results were presented in preliminary form in the proceedings of ICALP 2016 (Track A). The research leading to these results has received funding from the European Research Council under the European Union's Seventh Framework Programme (FP7/2007-2013) ERC grant agreement no. 334828. The article reflects only the authors’ views and not the views of the ERC or the European Commission. implies \( \{ \sigma(u), \sigma(v) \} \in E(H) \). If we identify the vertex set \( V(H) \) with a set \( Q = \{1, 2, \ldots, q\} \) of “colors,” then we can think of the mapping \( \sigma \) as specifying a coloring of the vertices \( G \), and we can interpret the graph \( H \) as specifying the allowed color adjacencies: adjacent vertices in \( G \) can be assigned colors \( i \) and \( j \) if and only if vertices \( i \) and \( j \) are adjacent in \( H \).

Now consider the graph \( G \) together with a collection of sets \( S = \{ S_v \subseteq Q : v \in V(G) \} \) specifying allowed colors at each of the vertices. A list \( H \)-coloring of \( (G, S) \) is an \( H \)-coloring \( \sigma \) of \( G \) satisfying \( \sigma(v) \in S_v \) for all \( v \in V \). In the literature, the set \( S_v \) is referred to as the “list” of allowed colors at vertex \( v \), but there is no implied ordering on the elements of \( S_v \)—\( S_v \) is just a set of allowed colors.

Suppose that \( H \) is a reflexive graph (i.e., a graph in which each vertex has a loop). Feder and Hell [1998] considered the complexity of determining whether a list \( H \)-coloring exists, given an input \( (G, S) \). They showed that the problem is in FP if \( H \) is an interval graph, and that it is NP-complete otherwise. Feder et al. [1999] studied the same problem in the case where \( H \) is irreflexive (i.e., \( H \) has no loops). They showed that the problem is in FP if \( H \) is a circular arc graph of clique covering number two (which is the same as being the complement of an interval bigraph [Hell and Huang 2004]), and that it is NP-hard otherwise. Finally, Feder et al. [2003] generalized this result to obtain a dichotomy for all \( H \). They introduced a new class of graphs, called bi-arc graphs, and showed that the problem is in FP if \( H \) is a bi-arc graph, and NP-complete otherwise.

We are concerned with the computational complexity of counting list \( H \)-colorings. Specifically, we are interested in how the complexity of the following computational problem depends on \( H \):

**Name.** \#LIST-\( H \)-COL.

**Instance.** A graph \( G \) and a collection of color sets \( S = \{ S_v \subseteq Q : v \in V(G) \} \), where \( Q = V(H) \).

**Output.** The number of list \( H \)-colorings of \( (G, S) \).

Note that it is of no importance whether we allow or disallow loops in \( G \)—a loop at vertex \( v \in V(G) \) can be encoded within the set \( S_v \)—so we adopt the convention that \( G \) is loop-free. As in the case of the decision problem, \( H \) is a parameter of the problem—it does not form part of the problem instance. Sometimes we obtain sharper results by introducing an additional parameter \( \Delta \), which is an upper bound on the degrees of the vertices of \( G \).

**Name.** \#LIST-\( H \)-COL(\( \Delta \)).

**Instance.** A graph \( G \) with maximum degree at most \( \Delta \) and a collection of color sets \( S = \{ S_v \subseteq Q : v \in V(G) \} \), where \( Q = V(H) \).

**Output.** The number of list \( H \)-colorings of \( (G, S) \).

Although \#LIST-\( H \)-COL and \#LIST-\( H \)-COL(\( \Delta \)) are the main objects of study in this article, we occasionally need to discuss the more basic versions of these problems without lists.

**Name.** \#\( H \)-COL.

**Instance.** A graph \( G \).

**Output.** The number of \( H \)-colorings of \( G \).

**Name.** \#\( H \)-COL(\( \Delta \)).

**Instance.** A graph \( G \) with maximum degree at most \( \Delta \).

**Output.** The number of \( H \)-colorings of \( G \).
To illustrate the definitions, let \( K_2 \) be the first graph illustrated in Figure 1, consisting of two connected vertices with a loop on vertex 2. \( \#K_2\)-Col is the problem of counting independent sets in a graph since the vertices mapped to color 1 by any homomorphism form an independent set. Let \( K_3 \) be the complete irreflexive graph on three vertices. Then \( \#K_2\)-Col is the problem of counting the proper 3-colorings of a graph. \( \#K_2\)-Col(\( \Delta \)) and \( \#K_3\)-Col(\( \Delta \)) are the corresponding problems where the instance is restricted to have maximum degree at most \( \Delta \).

The computational complexity of computing exact solutions to \( \#H\)-Col and \( \#H\)-Col(\( \Delta \)) was determined by Dyer and Greenhill [2000]. Dyer and Greenhill showed that \( \#H\)-Col is in FP if \( H \) is a complete reflexive graph or a complete bipartite irreflexive graph, and \( \#H\)-Col is \#P-complete otherwise. Their dichotomy also extends to the bounded-degree setting. In particular, they showed that if \( H \) is not a complete reflexive graph or a complete bipartite irreflexive graph, then there is an integer \( \Delta_H \) such that, for all \( \Delta \geq \Delta_H \), \( \#H\)-Col(\( \Delta \)) is \#P-complete.

Since the polynomial-time cases in Dyer and Greenhill’s dichotomy clearly remain solvable in polynomial time in the presence of lists, their dichotomy for \( \#H\)-Col carries over to \#List-\( H\)-Col without change. In other words, there is no difference between the complexity of \( \#H\)-Col and \#List-\( H\)-Col as far as exact computation is concerned. However, this situation changes if we consider approximate counting, and this is the phenomenon that we explore in this article.

With a view to reaching the statement of the main results as quickly as possible, we defer precise definitions of the relevant concepts to Section 2, and provide only indications here. From graph theory, we import a couple of well-studied hereditary graph classes, namely, bipartite permutation graphs and proper interval graphs. These classes each have several equivalent characterizations, and we give two of these, namely, excluded subgraph and matrix characterizations, in Section 2. It is sometimes useful to restrict the definition of proper interval graphs to simple graphs. However, in this article, as in Feder and Hell [1998], we consider reflexive proper interval graphs.

From complexity theory, we need the definitions of a Fully Polynomial Randomized Approximation Scheme (FPRAS), of approximation-preserving (AP) reducibility, and of the counting problems \#SAT and \#BIS. An FPRAS is a randomized algorithm that produces approximate solutions within a specified relative error with high probability in polynomial time. An AP reduction from problem \( \Pi \) to problem \( \Pi' \) is a randomized Turing reduction that yields close approximations to \( \Pi \) when provided with close approximations to \( \Pi' \). It meshes with the definition of an FPRAS in the sense that the existence of an FPRAS for \( \Pi' \) implies the existence of an FPRAS for \( \Pi \). The problem of counting satisfying assignments of a Boolean formula is denoted by \#SAT. Every counting problem in \#P is AP reducible to \#SAT, so \#SAT is said to be complete for \#P with respect to AP reductions. It is known that there is no FPRAS for \#SAT unless RP = NP. The problem of counting independent sets in a bipartite graph is denoted by \#BIS. The problem \#BIS appears to be of intermediate complexity: there is no known FPRAS for \#BIS (and it is generally believed that none exists), but there is no known AP reduction from \#SAT to \#BIS. Indeed, \#BIS is complete with respect to AP reductions for a complexity class \#RH\#P1, which will be discussed further in Section 5.

We say that a problem \( \Pi \) is \#SAT-hard if there is an AP reduction from \#SAT to \( \Pi \), that it is \#SAT-easy if there is an AP reduction from \( \Pi \) to \#SAT, and that it is \#SAT-equivalent if both are true. Note that all of these labels are about the difficulty of \textit{approximately} solving \( \Pi \), not about the difficulty of exactly solving it. Similarly, \( \Pi \) is said to be \#BIS-hard if there is an AP reduction from \#BIS to \( \Pi \), \#BIS-easy if there is an AP reduction from \( \Pi \) to \#BIS, and \#BIS-equivalent if there are both.

Our main result is a trichotomy for the complexity of approximating \#List-\( H\)-Col.
Theorem 1.1. Suppose that $H$ is a connected undirected graph (possibly with loops).

(i) If $H$ is an irreflexive complete bipartite graph or a reflexive complete graph, then \#\text{\textsc{List-H-Col}} is in $\text{FP}$.

(ii) Otherwise, if $H$ is an irreflexive bipartite permutation graph or a reflexive proper interval graph, then \#\text{\textsc{List-H-Col}} is \#\text{\textsc{Bis}}-equivalent.

(iii) Otherwise, \#\text{\textsc{List-H-Col}} is \#\text{\textsc{Sat}}-equivalent.

Remarks.

(1) The assumption that $H$ is connected is made without loss of generality, since the complexity of \#\text{\textsc{List-H-Col}} is determined by the maximum complexity of \#\text{\textsc{List-H'-Col}} over all connected components $H'$ of $H$. To see this, suppose that $H$ has connected components $H_1, \ldots, H_k$. We can reduce \#\text{\textsc{List-H'-Col}} to \#\text{\textsc{List-H-Col}} by using the lists to pick out the colors in $V(H_i)$. So hardness results for $H_i$ translate to hardness results for $H$. In the other direction, let $G_1, \ldots, G_m$ be the connected components of $G$. If we have algorithms for \#\text{\textsc{List-H_i-Col}} for $1 \leq i \leq k$, then we can solve \#\text{\textsc{List-H-Col}} for each instance $G_i$ to obtain the solution $Z_i$. Then, to get a solution $Z$ to \#\text{\textsc{List-H-Col}} with input $G$, we combine the solutions via

$$Z = \prod_{j=1}^{m} \sum_{i=1}^{k} Z_{i,j}.$$

(2) Part (ii) of Theorem 1.1 can be strengthened. For the graphs $H$ covered by this part of the theorem, \#\text{\textsc{List-H-Col}} is actually complete for the complexity class \#\text{\textsc{RhPi1}}. See Section 5.

Theorem 1.1 also extends to the bounded-degree case.

Theorem 1.2. Suppose that $H$ is a connected undirected graph (possibly with loops).

(i) If $H$ is an irreflexive complete bipartite graph or a reflexive complete graph, then, for all $\Delta$, \#\text{\textsc{List-H-Col}}($\Delta$) is in $\text{FP}$.

(ii) Otherwise, if $H$ is an irreflexive bipartite permutation graph or a reflexive proper interval graph, then, for all $\Delta \geq 6$, \#\text{\textsc{List-H-Col}}($\Delta$) is \#\text{\textsc{Bis}}-equivalent.

(iii) Otherwise, for all $\Delta \geq 6$, \#\text{\textsc{List-H-Col}}($\Delta$) is \#\text{\textsc{Sat}}-equivalent. Further, if $H$ is reflexive or irreflexive, \#\text{\textsc{List-H-Col}}($\Delta$) is \#\text{\textsc{Sat}}-equivalent for $\Delta \geq 3$.

Remarks.

(1) The condition $\Delta \geq 6$ is necessary for any hardness result that holds for all graphs $H$. In particular, there is a graph $H$ that is not an irreflexive complete bipartite graph or a reflexive complete graph but for which \#\text{\textsc{List-H-Col}}($\Delta$) has an FPTAS. An example is the graph $H = K_{\Delta}'$ for which Weitz’s self-avoiding walk algorithm [Weitz 2006] gives an FPTAS for \#\text{\textsc{List-H-Col}}($\Delta$) for $\Delta \leq 5$.

(2) In general, the lowest value of the degree bound $\Delta$ such that \#\text{\textsc{List-H-Col}}($\Delta$) is computationally hard depends on the particular graph $H$. Theorem 1.2 leaves open the cases $\Delta = 3, 4, 5$ (partly).

Theorems 1.1 and 1.2 follow from various constituent results, scattered throughout the article.

Proof of Theorems 1.1 and 1.2. Part (i) is trivial. Part (ii) follows from Lemmas 4.2 and 5.1. Part (iii) follows from Lemmas 3.1, 3.2, 3.3, 3.4, and 3.5. ∎

The most obvious issue raised by our theorems is the computational complexity of approximately counting $H$-colorings (in the absence of lists). This question was
extensively studied by Kelk [2003] and others, and appears much harder to resolve, even when there are no degree bounds. It is known [Galanis et al. 2016a] that \#H-COL is \#BIS-hard for every connected undirected graph \(H\) that is neither an irreflexive bipartite permutation graph nor a reflexive proper interval graph. It is not known for which connected \(H\) the problem is \#BIS-easy and for which it is \#SAT-equivalent, and whether one or the other always holds. In fact, there are specific graphs \(H\), two of them with as few as four vertices, for which the complexity of \#H-COL is unresolved. It is far from clear that a trichotomy should be expected, and in fact there may exist an infinite sequence \((H_t)\) of graphs for which \#H\(_t\)-COL is reducible to \#H\(_{t+1}\)-COL but not vice versa.

Some partial results and speculations can be found in Kelk [2003]. As we noted, \#H-COL and \#LIST-H-COL have the same complexity as regards exact computation. However, for approximate computation they are different, assuming (as is widely believed) that there is no AP reduction from \#SAT to \#BIS. An example is provided by the 2-wrench (see Figure 1). It is known [Dyer et al. 2003, Theorem 21] that \#2-wrench-COL is \#BIS-equivalent, but we know from Theorem 1.1 that the list version \#LIST-2-wrench-COL is \#SAT-equivalent since the 2-wrench is neither irreflexive nor reflexive. One way to see that \#LIST-2-wrench-COL is \#SAT-equivalent is to note that the 2-wrench contains \(K'_2\) as an induced subgraph, and that this induced subgraph can be “extracted” using the list constraints \(S_v = \{1, 2\}\), for all \(v \in V(G)\). But \#LIST-K'_2-COL is already known to be \#SAT-equivalent [Dyer et al. 2003, Theorem 1]. Indeed, systematic techniques for extracting hard induced subgraphs form the main theme of the article. It is for this reason that the theory of hereditary graph classes comes into play, just as in Feder et al. [2003].

Another recent research direction, at least in the unbounded-degree case, is toward weighted versions of list coloring. Here, the graph \(H\) is augmented by edge weights, specifying for each pair of colors \(i, j\) the cost of assigning \(i\) and \(j\) to adjacent vertices in \(G\). The computational complexity of obtaining approximate solutions was studied by Chen et al. [2015] and by Goldberg and Jerrum [2015]. There is a trichotomy for the case in which the input has no degree bound, but this is obtained in a context where individual spins at vertices are weighted and not just the interactions between pairs of adjacent spins. In this article, we have restricted the class of problems under consideration to ones having 0,1-weights on interactions, but at the same time we have restricted the problem instances to ones having 0,1-weights on individual spins. So we have a different tradeoff and the results from the references that we have just discussed do not carry across, even in the unbounded-degree setting. Indeed, toward the end of the article, in Section 6, we give an example to show that Theorem 1.1 is not simply the restriction of earlier results to 0,1-interactions (not merely because the proofs differ, but, in a stronger sense, because the results themselves are different).

Two things are appealing about our theorems. First, unlike the weighted classification theorems [Chen et al. 2015], here the truth is pleasingly simple. The trichotomies for \#LIST-H-COL and \#LIST-H-COL(\(\Delta\)) have a simple, natural formulation in terms of hereditary graph classes. Second, the proofs of the theorems are largely self-contained. The proofs do not rely on earlier works such as Chen et al. [2015], which require
multimorphisms and other deep results from universal algebra. The proof of Theorem 1.1 is self-contained apart from some very elementary and well-known starting points, which are collected together in Lemma 2.4. The proof of Theorem 1.2 is similarly self-contained, though it additionally relies on recent results [Sly 2010; Galanis et al. 2016b] about approximating the partition function of the antiferromagnetic Ising model on bounded-degree graphs (these are also contained in Lemma 2.4).

2. COMPLEXITY- AND GRAPH-THEORETIC PRELIMINARIES

As the complexity of computing exact solutions of \#\textsc{List-H-Col} is well understood, we focus on the complexity of computing approximations. The framework for this has already been explained in many papers, so we provide an informal description only here and direct the reader to Dyer et al. [2003] for precise definitions.

The standard notion of the efficient approximation algorithm is that of a Fully Polynomial Randomized Approximation Scheme (or FPRAS). This is a randomized algorithm that is required to produce a solution within relative error specified by a tolerance \( \varepsilon > 0 \), in time polynomial in the instance size and \( \varepsilon^{-1} \). Evidence for the nonexistence of an FPRAS for a problem \( \Pi \) can be obtained through Approximation Preserving reductions. These are randomized polynomial-time Turing reductions that preserve (closely enough) the error tolerance. The set of problems that have an FPRAS is closed under AP reducibility.

Every problem in \#P is AP reducible to \#\textsc{Sat}, so \#\textsc{Sat} is complete for \#P with respect to AP reductions. The same is true of the counting version of any NP-complete decision problem. It is known that these problems do not have an FPRAS unless RP = NP. On the other hand, using the bisection technique of Valiant and Vazirani [1986, Corollary 3.6], we know that \#\textsc{Sat} can be approximated (in the FPRAS sense) by a polynomial-time probabilistic Turing machine equipped with an oracle for the decision problem \textsc{Sat}.

In the statements and proofs of our theorems, we refer to two hereditary graph classes. A class of undirected graphs is said to be hereditary if it is closed under taking induced subgraphs. The classes of bipartite permutation graphs and proper interval graphs have been widely studied, and many equivalent characterizations of them are known. We are concerned with the excluded subgraph and matrix characterizations. These characterizations are well known in the area of structural graph theory, and most can be found in some form in the Information System on Graph Classes and their Inclusions (ISGCI) at www.graphclasses.org. However, it is not always easy for someone from outside the area to make the required connections, so we show in Appendix A how to derive the results we use from the published literature. Refer to the appendix also for proper citations.

The classes of bipartite permutation graphs and proper interval graphs are defined by certain intersection models and have the following excluded subgraph characterizations. A graph is a bipartite permutation graph if and only if it contains none of the following as an induced subgraph: \( X_3 \), \( X_2 \), \( T_2 \), or a cycle \( C_\ell \) of length \( \ell \) not equal to four. (Refer to Figure 2 for specifications of \( X_3 \), \( X_2 \), and \( T_2 \).) A graph is a proper interval graph if and only if it contains none of the following as an induced subgraph: the claw, the net, \( S_3 \), or a cycle \( C_\ell \) of length \( \ell \) at least four. (Refer to Figure 3 for specifications of the claw, the net, and \( S_3 \).)

These two graph classes also have matrix characterizations. Say that a 0,1-matrix \( A = (A_{i,j} : 1 \leq i \leq n, 1 \leq j \leq m) \) has staircase form if the 1s in each row are contiguous and the following condition is satisfied: letting \( \alpha_i = \min\{j : A_{i,j} = 1\} \) and \( \beta_j = \max\{i : A_{i,j} = 1\} \), we require that the sequences \( (\alpha_i) \) and \( (\beta_j) \) are nondecreasing. It is automatic that the columns share the contiguity and monotonicity properties, so the property of having staircase form is in fact invariant under matrix transposition.
A graph is a bipartite permutation graph if the rows and columns of its biadjacency matrix can be (independently) permuted so that the resulting biadjacency matrix has staircase form. A reflexive graph is a proper interval graph if there exists a permutation of the vertices so that the resulting adjacency matrix has staircase form.

As we mentioned in Section 1, an appealing feature of our theorems is that our proofs are largely self-contained. The only prerequisites for the proof are complexity results classifying some very well-known approximation problems. These are collected in Lemma 2.4. For this, we will use the graph $K'_2$ defined in Section 1—see Figure 1.

We will also use the following definitions.

**Definition 2.1.** Let $P_4$ be the path of length three (with four vertices).

**Definition 2.2.** Let $0 < \lambda < 1$ be a rational number and let $\Delta$ be a positive integer. We consider the following problem.

**Name.** AntiFerroIsing$_\lambda$($\Delta$).

**Instance.** A graph $G$ of maximum degree at most $\Delta$.

**Output.** The partition function of the antiferromagnetic Ising model with parameter $\lambda$ evaluated on instance $G$, that is,

$$Z_\lambda(G) = \sum_{\sigma : V \rightarrow \{\pm 1\}} \prod_{\{u, v\} \in E(G)} \lambda^{\delta(\sigma(u), \sigma(v))},$$

where $\delta(i, j)$ is 1 if $i = j$ and 0 otherwise.

**Definition 2.3.** #1P1NSat is the problem of counting the satisfying assignments of a CNF formula in which each clause has at most one negated literal and at most one unnegated literal.

**Remark.** Note that each clause of an instance of #1P1NSat is either a single literal or the relation “implies” between two variables.

**Lemma 2.4.** The following problems are #SAT-equivalent:

---

- $\#K'_2$-COL($\Delta$) for any $\Delta \geq 6$, and
- AntiFerroIsing$_\lambda$($\Delta$) for any $\Delta \geq 3$ and $0 < \lambda < (\Delta - 2)/\Delta$.

The following problems are #BIS-equivalent: $\#P_4$-COL($\Delta$) for $\Delta \geq 6$ and #1P1NSat.

**Proof.** As we noted in Section 1, $\#K'_2$-COL($\Delta$) is the problem of counting the independent sets of a graph of maximum degree at most $\Delta$. Without the degree bound, there is a very elementary proof that this problem is #SAT-equivalent (see Dyer et al. [2003, Theorem 3]). This suffices for the unbounded-degree case. For the bounded-degree case, the fact that counting independent sets is #SAT-equivalent for $\Delta \geq 6$ follows from Sly [2010, Theorem 2]. In fact, Sly shows in the proof of Sly [2010, Theorem 2] that an FPRAS for $\#K'_2$-COL($\Delta$) can be used (as an oracle) to provide a polynomial-time randomized algorithm for the NP-hard problem MAX-CUT. As is noted in the proof of Dyer et al. [2003, Theorem 4], this gives an AP reduction from #SAT to $\#K'_2$-COL($\Delta$), using the bisection technique of Valiant and Vazirani [1986, Corollary 3.6].

In the unbounded-degree case, there is an elementary proof that approximating the partition function of the antiferromagnetic Ising model is #SAT-equivalent. The proof is an easy reduction from the problem of counting large cuts in a graph (see Jerrum and Sinclair [1993, Thm 14]). In the bounded-degree case, we have to use more sophisticated results. The fact that AntiFerroIsing$_\lambda$($\Delta$) is #SAT-equivalent for $\Delta \geq 3$ and $0 < \lambda < (\Delta - 2)/\Delta$ comes from Galanis et al. [2016b, Theorem 1.2]. Similar to the paper of Sly mentioned earlier, the proof of Galanis et al. [2016b, Theorem 1.2] shows that an FPRAS for AntiFerroIsing$_\lambda$($\Delta$) can be used to provide a polynomial-time randomized
algorithm for \textsc{Max-Cut} and this can be turned into an AP reduction from \textsc{#Sat} to \textsc{AntiFerroising}(\Delta) using the bisection technique of Valiant and Vazirani.

Note that \textsc{#P}_\text{1}-\text{Col}(\Delta) is equivalent to the problem of counting independent sets in bipartite graphs of maximum degree at most \Delta (this is almost by definition since the end-points of the path can be interpreted as “in” the independent set and the other vertices of the path can be interpreted as “out”). It follows from Cai et al. [2016, Corollary 3] that the latter problem is \textsc{Bis}-equivalent for \Delta \geq 6, thus yielding that \textsc{#P}_\text{1}-\text{Col}(\Delta) is \textsc{Bis}-equivalent for \Delta \geq 6.

Finally, the \textsc{Bis}-equivalence of \textsc{$1p1$NSat} is given in Dyer et al. [2003, Theorem 5].

\section{\textsc{#Sat}-equivalence}

The aim of this section is to establish the \textsc{#Sat}-equivalence parts of Theorems 1.1 and 1.2.

\textbf{Lemma 3.1.} Suppose that \( H \) is a connected undirected graph. If \( H \) is neither reflexive nor irreflexive, then, for all \( \Delta \geq 6 \), \textsc{List-H-Col}(\Delta) is \textsc{Sat}-equivalent. Hence, \textsc{List-H-Col} is \textsc{Sat}-equivalent.

\textbf{Proof.} Let \( \Delta \geq 6 \). Since \( H \) is connected, it must contain \( K'_2 \) as an induced subgraph. So \textsc{#K}_2-\text{Col}(\Delta) is AP-reducible to \textsc{List-H-Col}(\Delta). By Lemma 2.4, \textsc{#K}_2-\text{Col}(\Delta) is \textsc{Sat}-equivalent.

\textbf{Remark.} We can see already that there is a complexity gap between \textsc{List-H-Col} and \textsc{H-Col}. The smallest witness to this gap is the 2-wrench mentioned in Section 1 (Figure 1). The problem \#2-wrench-Col is \textsc{Bis}-equivalent [Dyer et al. 2003, Theorem 21], whereas the problem \textsc{List-2-wrench-Col} is \textsc{Sat}-equivalent by Lemma 3.1. The point is that a graph \( H \) for which \textsc{H-Col} is \textsc{Bis}-easy may contain an induced subgraph \( H' \) for which \textsc{H'-Col} is \textsc{Sat}-equivalent. In other words, the class of graphs \( H \) such that \textsc{H-Col} is \textsc{Bis}-easy is not hereditary. Identifying \textsc{Sat}-equivalent subgraphs is the main analytical tool in this section. For this we use results in structural graph theory.

The gadgets that we use in our reductions in Sections 3.1 and 3.2 are of a particularly simple kind, namely, paths.\textsuperscript{1} Let the vertex set of the \( L \)-vertex path be \{1, 2, \ldots, \( L \)\}, where the vertices are numbered according to their position on the path. The end-vertices 1 and \( L \) are \textit{terminals}, which make connections with the rest of the construction. For each vertex \( 1 \leq k \leq L \), there is a set of allowed colors \( S_k \). We can describe a gadget by specifying \( L \) and specifying the sets \( (S_1, S_2, \ldots, S_L) \). In our application, each set \( S_i \) has cardinality 2, and \( S_1 = S_L \).

Fix a connected graph \( H \), possibly with loops. Our strategy for proving that \textsc{List-H-Col}(\Delta) is \textsc{Sat}-equivalent is to find a gadget \((i_1, j_1), (i_2, j_2), \ldots, (i_L, j_L)\) such that

(i) the sequence \((i_1, \ldots, i_L)\) is a path in \( H \), and likewise \((j_1, \ldots, j_L)\);

(ii) it is never the case that both \((i_k, j_{k+1}) \in E(H)\) and \((j_k, i_{k+1}) \in E(H)\); and

(iii) \( i_1 = j_L \) and \( j_1 = i_L \).

If we achieve these conditions, then, as we shall see, the colors at the terminals will be negatively correlated, and from there we will be able to encode instances of \textsc{AntiFerroising}(\Delta) for some integer \( \Delta \geq 3 \) and \( \lambda \in (0, \frac{\Delta-2}{\Delta}) \), and this is \textsc{Sat}-equivalent.

\textsuperscript{1}We were also able to make use of path gadgets in Goldberg and Jerrum [2015], though, as noted (see Section 1), the results unfortunately do not carry over to our setting. Here the use of structural graph theory makes the discovery of such gadgets pleasingly straightforward.
(Lemma 2.4). Note that although the ordering of elements within the sets $S_i$ is irrelevant to the workings of the gadget, we write the pairs in a specific order to bring out the path structure that we have just described.

Fix $H$ and let $A = A_{H}$ be the adjacency matrix of $H$. Denote by $A_{(i, j), (i', j')}$ the $2 \times 2$ submatrix of $A$ indexed by rows $i$ and $j$ and columns $i'$ and $j'$. We regard the indices in the notation $A_{(i, j), (i', j')}$ as ordered; thus, the first row of this $2 \times 2$ matrix comes from row $i$ of $A$ and the second from row $j$.

Given a gadget, that is, sequence $(\{i_1, j_1\}, \{i_2, j_2\}, \ldots, \{i_L, j_L\})$, consider the product of $2 \times 2$ submatrices of $A$:

$$D' = A_{(i_1, j_1), (i_2, j_2)}A_{(i_2, j_2), (i_3, j_3)} \cdots A_{(i_{L-1}, j_{L-1}), (i_L, j_L)}.$$  \hspace{1cm} (1)

If conditions (i) to (iii) for gadget construction are satisfied, then each of the $2 \times 2$ matrices in the product has $1$s on the diagonal; also, all of them have at least one off-diagonal entry that is $0$. Thus, each matrix has determinant $1$, from which it follows that $\det D' = 1$.

Now consider the matrix $D$ that is obtained by swapping the two columns of $D'$. This swap rectifies the “twist” that occurs in the passage from $(i_1, j_1)$ to $(i_L, j_L) = (j_1, i_1)$, but it also flips the sign of the determinant, leaving $\det D = -1$. Let $r = i_1 = j_L$ and $s = j_1 = i_L$. The matrix $D$ can be interpreted as giving the number of list $H$-colorings of the gadget when the $k$th vertex of the gadget (for $k \in \{1, \ldots, L\}$ is assigned the list $\{i_k, j_k\}$, so the terminals are restricted to colors in $[r, s]$. Thus:

— the entry in the first row and column of $D$ is the number of colorings with both terminals receiving color $r$,
— the entry in the first row and second column is the number of colorings with terminal $1$ receiving color $r$ and terminal $L$ receiving color $s$,
— the entry in the second row and first column is the number of colorings with terminal $1$ receiving color $s$ and terminal $L$ receiving color $r$, and finally
— the entry in the second row and second column is the number of colorings with both terminals receiving color $s$.

We call $D = D(\Gamma)$ the interaction matrix associated with the gadget $\Gamma$. Since $\det D < 0$, the gadget provides a negative correlation between the colors at the terminals, which, as we will see, will allow a reduction from $\text{ANTI\text{-}FERRO\text{-}ISING}_\Delta(\Delta)$. In Sections 3.1 and 3.2, we first demonstrate how to apply the technique to get the $\text{#SAT}$-equivalences in the unbounded-degree case. For these arguments, we intentionally keep the construction of the gadgets as simple as possible. While this would also lead to a value of $\Delta$ such that $\text{#LIST-H-COL}_\Delta$ is $\text{#SAT}$-equivalent, the value of $\Delta$ would be much larger than $6$. Thus, our remaining task will be to show how to refine the constructions to obtain the bounded-degree results of Theorem 1.2.

3.1. Irreflexive Graphs That Are Not Bipartite Permutation Graphs

**Lemma 3.2.** Suppose that $H$ is a connected undirected graph. If $H$ is irreflexive but it is not a bipartite permutation graph, then $\text{#LIST-H-COL}$ is $\text{#SAT}$-equivalent.

**Proof.** Graphs that are not bipartite permutation graphs contain one of the following as an induced subgraph: $X_3$, $X_5$, $T_2$, or a cycle of length other than $4$. (Refer to Figure 2.) We just have to show that $\text{#LIST-H-COL}$ is $\text{#SAT}$-equivalent when $H$ is any of these.

We consider the case $X_3$ in detail, and the others more swiftly, as they all follow the same general pattern. The gadget in this case is

$$\Gamma = (\{1, 2\}, \{4, 7\}, \{3, 6\}, \{4, 5\}, \{2, 1\}).$$

ACM Transactions on Computation Theory, Vol. 9, No. 2, Article 9, Publication date: April 2017.
Conditions (i) and (iii) for gadget construction are immediately satisfied, while condition (ii) is easy to check. Explicit calculation using Equation (1) yields

\[ D' = A_{(1,2),(4,7)}A_{(4,7),(3,6)}A_{(3,6),(4,5)}A_{(4,5),(2,1)} = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 3 & 5 \end{pmatrix}. \]

Swapping the columns of \( D' \) yields the interaction matrix \( D = (\frac{3}{2} \frac{2}{3}) \). As we explained earlier, \( \det D = -1 \). Obtaining a matrix \( D \) with negative determinant is moving in the right direction, but in order to encode antiferromagnetic Ising, we ideally want the matrix \( D = (D_{ij}) \) to also satisfy \( D_{11} = D_{22} \) and \( D_{12} = D_{21} \).

In the case of \( X_2 \), we have already \( D_{11} = D_{22} \), which makes the task easier. But we are not always in this favorable situation, so we introduce a technique that works in general for all of the graphs that we consider.

Observe that the graph \( X_3 \) has an automorphism of order two, \( \pi = (1, 2)(5, 7) \), that transposes vertices 1 and 2, which are the terminals of the gadget \( \Gamma \). Consider the gadget obtained from \( \Gamma \) by letting \( \pi \) act on the color sets, namely,

\[ \Gamma^\pi = ((\pi(1), \pi(2)), \{\pi(4), \pi(7)\}, \{\pi(3), \pi(6)\}, \{\pi(4), \pi(5)\}, \{\pi(2), \pi(1)\}) = ([2, 1], [4, 5], [3, 6], [4, 7], [1, 2]). \]

The interaction matrix \( D^\pi = (\frac{3}{2} \frac{5}{3}) \) corresponding to \( \Gamma^\pi \) is the same as \( D \), except that the rows and columns are swapped. Placing \( \Gamma \) and \( \Gamma^\pi \) in parallel, identifying the terminals, yields a composite gadget \( \Gamma^* \) whose interaction matrix is

\[ D^* = \begin{pmatrix} D_{11}D_{22} & D_{12}D_{21} \\ D_{21}D_{12} & D_{22}D_{11} \end{pmatrix} = \begin{pmatrix} 9 & 10 \\ 10 & 9 \end{pmatrix}. \]

Clearly the same construction will work for any graph \( H \) with an automorphism swapping the terminals of \( \Gamma \), provided \( D > 0 \). Note that the gadget \( \Gamma^* \) has maximum degree 2 (this observation will be important in the upcoming Lemma 3.3). Also, in general, \( \det D^* = D_{11}^2D_{22}^2 - D_{12}^2D_{21}^2 \). So we have an AP reduction from \textsc{AntiFerroIsing}_\lambda \) with \( \lambda = D_{11}D_{22}/(D_{12}D_{21}) \) to \textsc{List-H-Col}: given an instance \( G \) of \textsc{AntiFerroIsing}_\lambda \), simply replace each edge \( \{u, v\} \) of \( G \) with a copy of the gadget \( \Gamma^* \), identifying the two terminals of \( \Gamma^* \) with the vertices \( u \) and \( v \), respectively. (Since \( \Gamma^* \) is symmetric, it does not matter which is \( u \) and which is \( v \).) The problem \textsc{AntiFerroIsing}_\lambda \) is \#SAT-equivalent by Lemma 2.4. In the case \( H = X_3 \), we have \( \lambda = \frac{9}{10} \).

Now we present in less detail the gadgets for \( X_2, T_2 \), odd cycles, and even cycles of length at least 6. For \( X_2 \), the gadget is

\[ ([1, 2], [4, 7], [3, 2], [4, 6], [3, 1], [4, 5], [2, 1]). \]
with

\[ D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 5 & 8 \\ 8 & 13 \end{pmatrix}. \]

The interaction matrix is \( D = \begin{pmatrix} 8 & 5 \\ 13 & 8 \end{pmatrix} \). The graph \( X_2 \) has an automorphism transposing 1 and 2, yielding the symmetrized interaction matrix

\[ D^* = \begin{pmatrix} 64 & 65 \\ 65 & 64 \end{pmatrix}. \]

The remaining part of the analysis can be completed exactly as before. So that we don’t need to repeat this observation in the future, let us note at this point that all the graphs \( H \) we consider in this proof and the next have an automorphism of order 2 transposing the two distinguished terminal colors.

For \( T_2 \), the gadget is

\( (\{1, 2\}, \{5, 7\}, \{4, 2\}, \{3, 5\}, \{4, 1\}, \{5, 6\}, \{2, 1\}) \),

with

\[ D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 5 & 7 \\ 7 & 10 \end{pmatrix}. \]

The interaction matrix is \( D = \begin{pmatrix} 7 & 5 \\ 10 & 7 \end{pmatrix} \), yielding the symmetrized interaction matrix

\[ D^* = \begin{pmatrix} 49 & 50 \\ 50 & 49 \end{pmatrix}. \]

We will conclude by presenting the gadgets for odd cycles and for even cycles of length at least 6. The reason for doing so is that we will use the gadgets in the upcoming Lemma 3.3 to obtain the result for the bounded-degree case (and to present easy, self-contained proofs). For the unbounded-degree case, the remainder of the argument could be omitted since the result follows easily from the fact that the decision problem is NP-hard in these cases [Feder et al. 1999, Theorem 3.1].

For a cycle of even length \( q \geq 6 \), the gadget is

\( (\{1, 3\}, \{2, 4\}, \{1, 5\}, \ldots, \{1, q - 1\}, \{2, q\}, \{3, 1\}) \).

Note that, for convenience, the terminal colors in this case are 1 and 3, rather than 1 and 2, as elsewhere. To clarify the construction, we are setting \( L = q - 1 \), and the intention is that the path \( i_1, \ldots, i_L \) oscillates between 1 and 2, before moving at the last step to 3, while the path \( j_1, \ldots, j_L \) cycles clockwise from 3 to 1. We have

\[ D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}. \]

Note that this construction fails for \( q = 4 \)! The interaction matrix is \( D = \begin{pmatrix} 2 & 1 \\ 3 & 1 \end{pmatrix} \) and its symmetrized version is

\[ D^* = \begin{pmatrix} 2 & 3 \\ 3 & 2 \end{pmatrix}. \]

Finally, for a cycle of odd length \( q \), the gadget is

\( (\{1, 2\}, \{2, 3\}, \ldots, \{1, q - 1\}, \{2, q\}, \{1, q - 1\}, \ldots, \{2, 3\}, \{1, 2\}, \{2, 1\}) \).

To clarify the construction, we are setting \( L = 2q - 2 \), and the intention is that the path \( i_1, \ldots, i_L \) oscillates between 1 and 2, while the path \( j_1, \ldots, j_L \) cycles clockwise from 2
to $q$ and then anticlockwise back to 2 and then on to 1. We have

$$D' = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdots \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdots \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 1 \\ 1 & 1 \end{pmatrix}. $$

Note that this construction works even for $q = 3$. The corresponding interaction matrix is $D = \begin{pmatrix} 1 & 2 \\ 1 & 1 \end{pmatrix}$, and its symmetrized version is

$$D^* = \begin{pmatrix} 1 & 2 \\ 2 & 1 \end{pmatrix}. $$

In all cases, we obtain a reduction from $\text{AntiFerroIsing}_3(\Delta)$, completing the proof. $\square$

As noted earlier, we need to consider slightly more complicated gadgets to get the bounded-degree results of Theorem 1.2. Roughly, the idea is to implement thickenings of the gadgets using carefully chosen list colorings to keep the degree of the gadget small. This is achieved in the next lemma.

**Lemma 3.3.** Suppose that $H$ is a connected undirected graph. If $H$ is irreflexive but it is not a bipartite permutation graph, then for all $\Delta \geq 3$, $\text{List-H-Col}(\Delta)$ is $\text{SAT}$-equivalent.

**Proof.** As in the proof of Lemma 3.2, it suffices to show that, for all $\Delta \geq 3$, $\text{List-H-Col}(\Delta)$ is $\text{SAT}$-equivalent when $H$ is any of $X_3$, $X_2$, $T_2$, or a cycle of length other than 4. (Refer to Figure 2.)

Again, we consider the case $X_3$ in detail, and the other more swiftly, as they all follow the same general pattern. In Lemma 3.2, we constructed a gadget $\Gamma^*$ whose terminals have the allowed set of colors $\{1, 2\}$ and whose interaction matrix is given by $D^* = \begin{pmatrix} 9 & 10 \\ 10 & 9 \end{pmatrix}$ (see Equation (2)). The gadget $\Gamma^*$ was obtained by placing two paths in parallel and hence all of its vertices have degree 2. Note that all of the gadgets $\Gamma^*$ in the proof of Lemma 3.2 had the same property, so we will not repeat this observation later on.

Let $t \geq 0$ be an integer. We will denote by $D_t^*$ the matrix whose entries are obtained from $D^*$ by raising the entries of $D^*$ to the power $2^t$. Thus, in the case of $X_3$, $D_t^* = \begin{pmatrix} 9^{2^t} & 10^{2^t} \\ 10^{2^t} & 9^{2^t} \end{pmatrix}$. We will construct inductively a gadget $\Gamma_t^*$ with the following properties:

(i) The allowed colors of the terminals of $\Gamma_t^*$ will be $\{1, 2\}$ for odd $t$ and $\{5, 7\}$ for even $t$.

(ii) The two terminals of $\Gamma_t^*$ will each have degree 1, and all other vertices of $\Gamma_t^*$ will have degree at most 3.

(iii) The interaction matrix of $\Gamma_t^*$ will be $D_t^*$.

We first do the base case $t = 0$. Let $u$, $v$ be the terminals of $\Gamma^*$ and recall that their allowed sets of colors is $\{1, 2\}$. The gadget $\Gamma^*_0$ (i.e., $t = 0$) is obtained from $\Gamma^*$ by adding two new vertices $u_0$, $v_0$ and adding the edges $(u, u_0)$, $(v_0, v)$. For all vertices that were initially in $\Gamma^*$, we keep their sets of allowed colors the same, and for $u_0$, $v_0$, we restrict their allowed colors to the set $\{5, 7\}$. Finally, we set the terminals of $\Gamma^*_0$ to be $u_0$, $v_0$. It is easy to see that $\Gamma^*_0$ satisfies properties (i) and (ii) for $t = 0$. To find the interaction matrix of $\Gamma^*_0$, note that color 1 is adjacent to color 5 in $X_3$ but not color 7, and similarly color 2 is adjacent to color 7 in $X_3$ but not color 5. It follows that $D(\Gamma^*_0) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 9 & 10 \\ 10 & 9 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = D_0^*$, proving that $\Gamma^*_0$ satisfies all properties (i) to (iii), as desired.
We now carry out the induction step, so assume that for an integer \( t \geq 0 \), we have \( \Gamma^* \), which satisfies all properties (i) to (iii). Let \( u_t, v_t \) be the terminals of \( \Gamma^*_t \). Take two copies of \( \Gamma^*_t \) and place them in parallel, identifying the two copies of \( u_t \) into one vertex and similarly for the two copies of \( v_t \). Also, add two new vertices \( u_{t+1}, v_{t+1} \) and add the edges \((u_{t+1}, u_t), (v_{t+1}, v_t)\). For all vertices that belonged to one of the copies of \( \Gamma^*_t \), we keep their sets of allowed colors the same, and for \( u_{t+1}, v_{t+1} \), we restrict their allowed colors to the set \( \{1, 2\} \) if \( t \) is even and to \( \{5, 7\} \) if \( t \) is odd. The final graph is the gadget \( \Gamma^*_t \) with terminals \( u_{t+1}, v_{t+1} \). It is immediate that \( \Gamma^*_t \) satisfies property (i) and, using the fact that \( \Gamma^*_t \) satisfies property (ii), it is simple to check that \( \Gamma^*_t \) satisfies property (ii) as well. To see property (iii), note by construction that the set of allowed colors of \( \Gamma^*_t \), for odd \( t \), is either \( \{1, 2\} \) or \( \{5, 7\} \), identifying the two terminals of \( \Gamma^*_t \), which satisfies all properties (i) to (iii). Let \( \lambda_t \) be the terminals of \( \Gamma^*_t \) such that \( \lambda_t \) is adjacent to \( \lambda_t \) in Lemma 3.2, this establishes condition (3). (Note that \( \lambda_t \) are either \( \{1, 2\} \) or \( \{5, 7\} \) for odd \( t \) or \( \{5, 7\} \) and \( \{1, 2\} \) for odd \( t \), respectively. Taking also into consideration the 2-thickening of the gadget \( \Gamma^*_t \), we obtain

\[
D(\Gamma^*_t) = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} (9^2)^2 & (10^2)^2 \\ (10^2)^2 & (9^2)^2 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} = D^r_{t+1},
\]

thus proving property (iii) as well. This completes the induction and hence the construction of the gadgets \( \Gamma^*_t \).

Let \( \lambda_t = 9^2/10^2 \) for an arbitrary integer \( t \geq 0 \). For every positive integer \( \Delta \geq 3 \), we now have an AP reduction from \text{AntiFerroIsing}_{\lambda_t}(\Delta) \text{ to } \#\text{LIST-H-Col}(\Delta) \text{; given an instance } G \text{ of } \text{AntiFerroIsing}_{\lambda_t}(\Delta), \text{ simply replace each edge } \{u, v\} \text{ of } G \text{ with a copy of the gadget } \Gamma^*_t \text{, identifying the two terminals of } \Gamma^*_t \text{ with the vertices } u \text{ and } v \text{, respectively. Using property (ii) of the gadget } \Gamma^*_t \text{, the resulting instance of } \#\text{LIST-X3-Col} \text{ has maximum degree at most } \Delta. \text{ We can clearly find a positive integer } t \text{ such that } \lambda_t < (\Delta - 2)/\Delta, \text{ so that } \text{AntiFerroIsing}_{\lambda_t}(\Delta) \text{ is } \#\text{SAT-equivalent by Lemma 2.4. Thus, we obtain that } \#\text{LIST-X3-Col}(\Delta) \text{ is } \#\text{SAT-equivalent for all } \Delta \geq 3, \text{ as claimed.}

To expedite the proof of the remaining cases for the graph \( H \), note that the part of the argument that was crucial in the construction of the gadgets \( \Gamma^*_t \) from \( \Gamma^* \) was the following condition:

\[
\text{for the allowed colors } r, s \text{ for the terminals of } \Gamma^*, \text{ there exist colors } r', s' \text{ such that } r \text{ is adjacent to } r' \text{ but not } s', \text{ and } s \text{ is adjacent to } s' \text{ but not } r'. \tag{3}
\]

Note that in some circumstances, it will suffice to have \( \{r, s\} = \{r', s'\} \). For example, \( r' = s \text{ and } s' = r \) is a solution if \( \{r, s\} \) is an edge of \( H \) and there are no self-loops on \( r \) or \( s \). If condition (3) holds for a graph \( H \) and the respective gadget \( \Gamma^* \) in Lemma 3.2, this argument yields gadgets \( \Gamma^*_t \) satisfying properties (i) to (iii). We next check that this is the case for all the graphs \( H \) under consideration with the single exception of the cycle of length 3.

For \( X_3 \), the set of allowed colors for the terminals of \( \Gamma^* \), in Lemma 3.2 was \( \{1, 2\} \) and hence the colors in \( \{5, 7\} \) establish condition (3).

For \( T_2 \), the set of allowed colors for the terminals of \( \Gamma^* \), in Lemma 3.2 was \( \{1, 2\} \) and hence the colors in \( \{6, 7\} \) establish condition (3).

For a cycle of even length \( q \geq 6 \), the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.2 was \( \{1, 3\} \) and hence the colors in \( \{q, 4\} \) establish condition (3).

For a cycle of odd length \( q \geq 3 \), the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.2 was \( \{1, 2\} \) and hence the colors in \( \{2, 1\} \) establish condition (3). (Note that there are no self-loops on \( 1, 2 \)).

Thus, when \( H \) is any of \( X_3, X_2, T_2 \), or a cycle of length other than 4, we obtain, for all \( \Delta \geq 3 \), for some \( 0 < \lambda < (\Delta - 2)/\Delta \), an AP reduction from \text{AntiFerroIsing}_{\lambda}(\Delta) \text{ to } \#\text{LIST-H-Col}(\Delta). \text{ By Lemma 2.4, AntiFerroIsing}_{\lambda}(\Delta) \text{ is } \#\text{SAT-equivalent, so } \#\text{LIST-H-Col}(\Delta) \text{ is also } \#\text{SAT-equivalent.} \]
3.2. Reflexive Graphs That Are Not Proper Interval Graphs

**Lemma 3.4.** Suppose that $H$ is a connected undirected graph. If $H$ is a reflexive graph that is not a proper interval graph, then $\#\text{List-}H\text{-Col}$ is $\#\text{SAT}$-equivalent.

**Proof.** The line of argument is the same as in the proof of Lemma 3.2. Graphs that are not proper interval graphs contain one of the following as an induced subgraph: the claw, the net, $S_3$, or a cycle of length at least 4. (Refer to Figure 3 but note that loops are omitted.) We just have to show that $\#\text{List-}H\text{-Col}$ is $\#\text{SAT}$-equivalent when $H$ is any of these.

For the claw, the gadget we use is

$$((1, 2), (4, 2), (3, 4), (4, 1), (2, 1)),$$

with

$$D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 3 & 5 \end{pmatrix},$$

and interaction matrix $D = \begin{pmatrix} 3 & 2 \\ 5 & 3 \end{pmatrix}$. The claw has an automorphism transposing vertices 1 and 2 (as do the other graphs $H$ that we meet in this proof), so we can complete the reduction from the partition function of the antiferromagnetic Ising model as in the proof of Lemma 3.2.

For the net, the gadget is

$$((1, 2), (4, 6), (3, 2), (3, 1), (4, 5), (2, 1)),$$

with

$$D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 2 & 3 \\ 3 & 5 \end{pmatrix},$$

and interaction matrix $D = \begin{pmatrix} 3 & 2 \\ 5 & 3 \end{pmatrix}$.

For $S_3$, it is

$$((1, 2), (3, 6), (3, 5), (3, 4), (2, 1)),$$

with

$$D' = \begin{pmatrix} 1 & 0 \\ 1 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 1 \\ 1 & 2 \end{pmatrix},$$

and interaction matrix $D = \begin{pmatrix} 1 & 1 \\ 0 & 2 \end{pmatrix}$.

Finally, for the cycle of length $q \geq 4$, it is

$$((1, 2), (1, 3), \ldots, (1, q - 1), (1, q), (2, 1)).$$

Here $L = q$, and the path $i_1, \ldots, i_L$ cycles round the loop at vertex 1 and moves to 2 at the last step, while the path $j_1, \ldots, j_L$ cycles clockwise from vertex 2 to vertex 1. We
have
\[ D' = \begin{pmatrix} 1 & 0 \\ 1 & 2 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \cdots \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} \begin{pmatrix} 1 & 1 \\ 0 & 1 \end{pmatrix} = \begin{pmatrix} 1 & 2 \\ 1 & 3 \end{pmatrix}, \]
and the interaction matrix is \( D = \begin{pmatrix} 2 & 1 \\ 3 & 1 \end{pmatrix} \). This completes the analysis of the excluded subgraphs and the proof. \( \Box \)

**Lemma 3.5.** Suppose that \( H \) is a connected undirected graph. If \( H \) is a reflexive graph that is not a proper interval graph, then, for \( \Delta \geq 3 \), \( \text{\#LIST-H-Col}(\Delta) \) is \( \text{\#SAT-equivalent} \).

**Proof.** Similarly to our derivation of Lemma 3.3 from Lemma 3.2, to derive the lemma from Lemma 3.4, we only need to check that condition (3) holds when \( H \) is the claw, the net, \( S_3 \), or a cycle of length at least 4 (we iterate the condition for convenience):

for the allowed colors \( r, s \) for the terminals of \( \Gamma^* \), there exist colors \( r', s' \) such that \( r \) is adjacent to \( r' \) but not \( s' \), and \( s \) is adjacent to \( s' \) but not \( r' \).

For the claw, the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.4 was \( \{1, 2\} \) and hence the colors in \( \{1, 2\} \) establish the condition (note the self-loops on colors 1,2).

For the net, the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.4 was \( \{1, 2\} \) and hence the colors in \( \{1, 2\} \) establish condition (3).

For \( S_3 \), the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.4 was \( \{1, 2\} \) and hence the colors in \( \{1, 2\} \) establish condition (3).

For a cycle of length \( q \geq 4 \), the set of allowed colors for the terminals of \( \Gamma^* \) in Lemma 3.2 was \( \{1, 2\} \) and hence the colors in \( \{q, 3\} \) establish condition (3). \( \Box \)

**4. \#BIS-HARDNESS**

We will use the following lemma.

**Lemma 4.1.** For all \( \Delta \geq 6 \), \( \text{\#LIST-P_3^*-Col}(\Delta) \) is \( \text{\#BIS-hard} \).

**Proof.** Let \( \Delta \geq 6 \). We will reduce \( \text{\#P_4-Col}(\Delta) \) to \( \text{\#LIST-P_3^*-Col}(\Delta) \). Consider an instance \( G \) of \( \text{\#P_4-Col}(\Delta) \). We may assume that \( G \) is a bipartite graph with bipartition \((V_1, V_2)\).

Recall \( P_3^* \) from Figure 1 and the colors 1,2,3 there. For each \( v \in V_1 \), let \( S_v = \{1, 2\} \), and for each \( v \in V_2 \), let \( S_v = \{2, 3\} \). Consider the instance \((G, S)\) of \( \text{\#LIST-P_3^*-Col}(\Delta) \). It is immediate to see that list \( P_3^* \)-colorings of \((G, S)\) are in one-to-one correspondence with \( P_4 \)-colorings of \( G \). This completes the reduction, so the result follows from Lemma 2.4. \( \Box \)

We now deal with the \#BIS-equivalent cases in Theorems 1.1 and 1.2.

**Lemma 4.2.** Suppose that \( H \) is a connected undirected graph. If \( H \) is not a reflexive complete graph or an irreflexive complete bipartite graph, then, for all \( \Delta \geq 6 \), \( \text{\#LIST-H-Col}(\Delta) \) is \( \text{\#BIS-hard} \). Hence, \( \text{\#LIST-H-Col} \) is \( \text{\#BIS-hard} \).

**Proof.** The case when \( H \) is neither reflexive nor irreflexive is covered by Lemma 3.1 (since \#BIS is \#AP reducible to \#SAT).

So assume next that \( H \) is reflexive but not complete. We will show that \( H \) contains an induced \( P_3^* \), which suffices by Lemma 4.1. To find the induced \( P_3^* \), among the non-adjacent pairs of vertices \( i, j \in V(H) \), choose a pair that minimizes the graph distance between \( i \) and \( j \). Minimality easily implies that the graph distance between \( i \) and \( j \) is in fact 2. Let \( k \in V(H) \) be a vertex that is adjacent to both \( i \) and \( j \). Then the vertices \((i, k, j)\) induce a \( P_3^* \).

Finally, assume that \( H \) is irreflexive but that it is not a complete bipartite graph.
**Case 1.** If \( H \) is bipartite, then, among the pairs of nonadjacent vertices \( i, j \in V(H) \) on opposite sides of the bipartition, choose the pair that minimizes graph distance between \( i \) and \( j \). Minimality easily implies that the graph distance between \( i \) and \( j \) is in fact 3. Thus, \( H \) contains an induced \( P_4 \), the path of length 3. For \( \Delta \geq 6 \), the problem \( \#P_{\Delta} - \text{Col}(\Delta) \) is equivalent to \( \#\text{BIS} \) by Lemma 2.4.

**Case 2.** If \( H \) is not bipartite, it is not a bipartite permutation graph either (trivially). By Lemma 3.3, for \( \Delta \geq 3 \), \( \#\text{List-}H\text{-Col}(\Delta) \) is \( \#\text{SAT} \)-equivalent. Once again, the result follows since \( \#\text{BIS} \), like every other approximate counting problem in \( \#\text{P} \), is \( \text{AP}\text{-reducible to } \#\text{SAT} \). \( \square \)

**Remark.** Galanis et al. [2016a] prove a result that is related to, but incomparable to, Lemma 4.2. Namely, in the absence of lists, and in the absence of degree bounds, they show that if \( H \) is not a reflexive complete graph or an irreflexive complete bipartite graph, then \( \#H\text{-Col} \) is \( \#\text{BIS} \)-hard. In the unbounded-degree case, this result is stronger than Lemma 4.2 (because no lists are involved). However, it does not apply in the bounded-degree case. Also, the proof is quite long and technical.

5. \#BIS-EASINESS

**Lemma 5.1.** Suppose that \( H \) is a connected undirected graph. If \( H \) is an irreflexive bipartite permutation graph or a reflexive proper interval graph, then \( \#\text{List-}H\text{-Col} \) is \( \#\text{BIS} \)-easy.

**Proof.** The reduction is done in a more general weighted setting by Chen et al. [2015]: see the proofs of Lemmas 45 and 46 of that article. However, in the current context, we can simplify the reduction significantly (eliminating the need for multimorphisms and other concepts from universal algebra), and we can also extract a slightly stronger statement, which will be presented in Corollaries 5.2 and 5.3. The target problem for our reduction is \( \#1\text{P1NSAT} \) (see Definition 2.3), which is \#BIS-equivalent by Lemma 2.4.

First, suppose that \( H \) is a connected irreflexive bipartite permutation graph whose biadjacency matrix \( B \) has \( q_1 \) rows and \( q_2 \) columns and is in staircase form. Let \( A \) be the (permuted adjacency) matrix \( \left( \begin{array}{c|c} B & 0 \\ \hline 0 & B^T \end{array} \right) \), which is formally defined as follows:

\[
A_{i,j} = \begin{cases} 
B_{i,j}, & \text{if } 1 \leq i \leq q_1, 1 \leq j \leq q_2 \\
B_{j-q_2,j-q_1}, & \text{if } q_1 + 1 \leq i \leq q_1 + q_2, q_2 + 1 \leq j \leq q_2 + q_1 \\
0, & \text{otherwise.}
\end{cases}
\]

Let \( q = q_1 + q_2 \). For each \( i \in \{1, \ldots, q\} \), let \( \alpha_i = \min\{j : A_{i,j} = 1\} \) and let \( \beta_i = \max\{j : A_{i,j} = 1\} \). Since \( B \) is in staircase form, so is \( A \), so the sequences \( (\alpha_i) \) and \( (\beta_i) \) are nondecreasing. Let \( r_1, \ldots, r_q \) be the colors associated with the rows of \( A \) and \( c_1, \ldots, c_q \) be the colors associated with the columns of \( A \) in order. Note that \( \{r_1, \ldots, r_q\} \) and \( \{c_1, \ldots, c_q\} \) are different permutations of the vertices of \( H \).

Suppose that \( (G, S) \) is an instance of \#List-\( H \)-Col. Assume without loss of generality that \( G \) is bipartite. Otherwise, it has no \( H \)-colorings. Let \( V_1(G) \cup V_2(G) \) be the bipartition of \( V(G) \). We will construct an instance \( \Psi \) of \#1P1NSat such that the number of satisfying assignments to \( \Psi \) is equal to the number of list \( H \)-colorings of \((G, S)\).

The variable set of \( \Psi \) is \( \mathbf{x} = \{x_i^u : u \in V(G) \text{ and } 0 \leq i \leq q\} \). For each vertex \( u \in V(G) \), we introduce the clauses \( (x_i^u) \) and \( (\neg x_i^u) \). Also, for each \( j \in \{1, \ldots, q\} \), we introduce the clause \( \text{IMP}(x_j^u, x_{j-1}^u) \). Denote by \( \Psi_V(x) \) the formula obtained by taking the conjunction of all these clauses.

We will interpret the assignment to the variables in \( x \) as an assignment \( \sigma \) of colors to the vertices of \( G \) according to the following rule. If \( u \in V_1(G) \), then \( x_i^u = 1 \) if and only if \( \sigma(u) = r_j \) for some \( j > i \). If \( u \in V_2(G) \), then \( x_i^u = 1 \) if and only if \( \sigma(u) = c_j \) for some
\( j > i \). Note that there is a one-to-one correspondence between assignments to \( x \) that satisfy the clauses in \( \Psi_V(x) \) and assignments \( \sigma \) of colors to the vertices of \( G \).

We now introduce further clauses to enforce the constraint on colors received by adjacent vertices. For each edge \( \{u, v\} \in E(G) \) with \( u \in V_1(G) \) and \( v \in V_2(G) \), and for each \( i \in \{1, \ldots, q\} \), we add the clauses \( \text{IMP}(x_{i-1}^u, x_{i-1}^v) \) and \( \text{IMP}(x_{k_i}^u, x_{k_i}^v) \). Denote by \( \Psi_E(x) \) the formula obtained by taking the conjunction of all of these clauses.

We next argue that there is a bijection between \( H \)-colorings of \( G \) and satisfying assignments to \( \Psi_V(x) \land \Psi_E(x) \).

In one direction, suppose \( \sigma \) is an \( H \)-coloring of \( G \). We wish to show that all clauses in \( \Psi_E(x) \) are satisfied. Consider an edge \( \{u, v\} \in E(G) \) with \( u \in V_1(G) \) and \( v \in V_2(G) \).

—Consider the corresponding clause \( \text{IMP}(x_{i-1}^u, x_{i-1}^v) \). The clause is satisfied unless \( x_{i-1}^u = 1 \), so suppose \( x_{i-1}^u = 1 \). Then, by the interpretation of assignments, \( \sigma(u) = r_j \) for some \( j \geq i \). Since \( \sigma \) is an \( H \)-coloring, this implies that \( \sigma(v) = c_k \) for some \( k \geq \alpha_i \). But by the interpretation of assignments, this means that \( x_{i-1}^v = 1 \), so the clause is satisfied.

—Consider the other corresponding clause \( \text{IMP}(x_{k_i}^u, x_{k_i}^v) \). Suppose that \( x_{k_i}^u = 1 \) (otherwise, the clause is satisfied). Then, by the interpretation of assignments, \( \sigma(v) = c_k \) for some \( k > \beta_i \). Since \( \sigma \) is an \( H \)-coloring, this implies that \( \sigma(u) = r_j \) for some \( j > i \), which implies by the interpretation of assignments that \( x_{k_i}^u = 1 \), so the clause is satisfied.

In the other direction, suppose \( \Psi_V(x) \land \Psi_E(x) \) is satisfied. Consider an edge \( \{u, v\} \in E(G) \) with \( u \in V_1(G) \) and \( v \in V_2(G) \) and suppose that \( \sigma(u) = r_i \).

—In the corresponding assignment, \( x_{i-1}^u = 1 \), so by the clause \( \text{IMP}(x_{i-1}^u, x_{i-1}^v) \), we have \( x_{i-1}^v = 1 \), so \( \sigma(v) = c_k \) for some \( k \geq \alpha_i \).

—In the corresponding assignment, \( x_{i}^u = 0 \), so by the clause \( \text{IMP}(x_{k_i}^u, x_{k_i}^v) \), \( x_{k_i}^v = 0 \), so \( \sigma(v) = c_k \) for some \( k \leq \beta_i \).

We conclude that the colors \( \sigma(u) \) and \( \sigma(v) \) are adjacent in \( H \). This holds for every edge, so \( \sigma \) is an \( H \)-coloring of \( G \).

Finally, we add clauses to deal with lists. A color assignment \( \sigma(u) = r_i \) with \( u \in V_1(G) \) is uniquely characterized by \( x_{i-1}^u = 1 \) and \( x_i^u = 0 \). So we can eliminate the possibility of \( \sigma(u) = r_i \) by introducing the clause \( \text{IMP}(x_{i-1}^u, x_i^u) \). A similar clause will forbid a vertex \( v \in V_2(G) \) to receive color \( c_j \). Let \( \Psi_L(x) \) be the conjunction of all such clauses, arising from the lists in \( S \). Let \( \Psi(x) = \Psi_V(x) \land \Psi_E(x) \land \Psi_L(x) \).

Then the list \( H \)-colorings of \((G, S)\) are in bijection with the satisfying assignments to \( \Psi(x) \). This concludes the case where \( H \) is an irreflexive bipartite permutation graph.

The situation where \( H \) is a reflexive proper interval graph is exactly the same except that we can just take the adjacency matrix \( A \) of \( H \) to be in staircase form, so \( \{r_1, \ldots, r_q\} \) is the same permutation as \( \{c_1, \ldots, c_q\} \). We do not require \( G \) to be bipartite, so the interpretation of the assignment of the variables in \( x \) as an assignment \( \sigma \) of colors to the vertices of \( \tilde{G} \) is the same for all vertices in \( G \).

As remarked in Section 1, we can slightly strengthen the statement of Lemma 5.1. For this, we will need the definition of the complexity class \#RH1_1 from Dyer et al. [2003, Section 5], which builds on the logical framework of Saluja et al. [1995]. A vocabulary is a finite set of relation symbols. These are used to define an instance of a \#P problem. In the case of \#BIS, the relevant vocabulary consists of a binary relation \( \sim \) (representing adjacency in the input graph \( G \)) and a unary relation \( L \) (representing one side of the bipartition—for concreteness, the “left” side \( V_1(G) \)).
A problem in \#P can be represented by a first-order sentence using the relevant vocabulary. The sentence may use variables to represent elements of the universe, it may use relations in the vocabulary, and it may also use some new relation symbols \(X_0, \ldots, X_q\) (for some \(q\)). (The fact that the sentence is “first order” just means that it may quantify over variables, but not over relations.)

The input to the \#P problem is a structure consisting of a universe together with interpretations of all relations in the vocabulary. The problem is to count the number of ways that the interpretations can be extended to interpretations of the new relation symbols \(X_0, \ldots, X_q\) and of any free variables in the sentence to obtain a model of the sentence. Note that the input is an arbitrary structure over the vocabulary, but, for example, only some structures over the vocabulary \(\{\sim, L\}\) correspond to undirected bipartite graphs, so in the logical framework we define \#BIS as follows.

**Name.** \#BIS.

**Instance.** A structure consisting of a finite universe \(V\) and interpretations of the binary relation \(\sim\) and the unary relation \(L\).

**Output.** If the structure corresponds to an undirected bipartite graph \(G\) where \(L\) represents one side of the bipartition, then the output is the number of independent sets of \(G\). Otherwise, it is 0.

**Remark.** Since it is easy to check in polynomial time whether a structure over \(\{\sim, L\}\) does represent an undirected bipartite graph with bipartition given by \(L\), this version of \#BIS is AP interreducible with the usual version.

In the class \#RH\Pi_1, syntactic restrictions are placed on the first-order sentence representing the problem. It consists of universal quantification (over variables) followed by an unquantified CNF formula, which satisfies the special property that each clause has at most one occurrence of an unnegated relation symbol from \(X_0, \ldots, X_q\) and at most one occurrence of a negated relation symbol from \(X_0, \ldots, X_q\).

It is known that \#BIS and many other problems that are \#BIS-equivalent are contained in \#RH\Pi_1, and in fact that they are complete for \#RH\Pi_1 with respect to \#P reductions. To illustrate the definitions, it is perhaps useful to give a simple example illustrating the fact that \#BIS, as defined earlier, is in \#RH\Pi_1. A similar example appears in Dyer et al. [2003]. A suitable sentence using the vocabulary \(\{\sim, L\}\) is

\[
\forall u, v \quad (L(u) \land u \sim v \land X_0(u) \Rightarrow X_0(v)) \land \\
(u \sim v \Rightarrow v \sim u) \land (\neg(u \sim v) \lor L(u) \lor L(v)) \land (\neg(u \sim v) \lor \neg L(u) \lor \neg L(v)).
\]

Note that the clauses

\[
(u \sim v \Rightarrow v \sim u) \land (\neg(u \sim v) \lor L(u) \lor L(v)) \land (\neg(u \sim v) \lor \neg L(u) \lor \neg L(v))
\]

ensure that the sentence has no models unless the input corresponds to an undirected bipartite graph \(G\) where the relation \(L\) corresponds to one side of the bipartition. When this is the case, each interpretation of the new unary relation symbol \(X_0\) corresponds to an independent set of \(G\) in the sense that \(\{u \in L \cap X_0\} \cup \{u \in L \cap X_0\}\) is an independent set, so independent sets are in one-to-one correspondence with interpretations of \(X_0\).

Having defined \#RH\Pi_1, we are now ready to strengthen Lemma 5.1 to show that, if \(H\) is an irreflexive bipartite permutation graph or a reflexive proper interval graph, then \#LIST-\#H-COL \in \#RH\Pi_1. In order to proceed, we must define versions of these in the logical framework, as we did for \#BIS. First, suppose that \(H\) is a connected irreflexive bipartite permutation graph with \(q\) vertices. Our vocabulary will consist of the vocabulary \(\{\sim, L\}\), together with \(q\) unary relations \(U_1, \ldots, U_q\). The intention is that \(U_i\) will represent the vertices of \(G\) that are allowed color \(i\).
Name. \textsc{List-H-Col}.

Instance. A structure consisting of a finite universe \( V \) and interpretations of the relations in the vocabulary \( \{\sim, L, U_1, \ldots, U_q\} \).

Output. If the structure consisting of \( V, \sim \), and \( L \) corresponds to an undirected bipartite graph \( G \) where \( L \) represents one side of the bipartition, then the output is the number of list \( H \)-colorings of \((G, S)\) where, for each \( v \in V \), \( S_v = \{i : v \in U_i\} \) and \( S = \{S_v\} \). Otherwise, the output is 0.

Since it is easy to check in polynomial time whether a structure over \( \{\sim, L\} \) does represent an undirected bipartite graph, with bipartition given by \( L \), and since \( H \) is irreflexive and bipartite (so \( G \) has no \( H \)-colorings unless it is also bipartite), the problem \#\textsc{List-H-Col} is AP interreducible with the usual version.

Corollary 5.2. Suppose that \( H \) is a connected undirected graph. If \( H \) is an irreflexive bipartite permutation graph, then the problem \#\textsc{List-H-Col} is in \#\textsc{RHPI}.

Proof. The proof is essentially a translation of the reduction from Lemma 5.1 into the logical setting of \#\textsc{RHPI}. The sentence representing the problem \#\textsc{List-H-Col} is of the form \( \forall u, v \Phi(u, v) \), where \( \Phi(u, v) \) is a conjunction of clauses. As in the \#\textsc{Bis} example, we include the clauses

\[
(u \sim v \Rightarrow v \sim u) \land (\neg(u \sim v) \lor L(u) \lor L(v)) \land (\neg(u \sim v) \lor \neg L(u) \lor \neg L(v))
\]

to ensure that the output is 0 unless the structure consisting of \( V, \sim \), and \( L \) corresponds to an undirected bipartite graph \( G \) with bipartition given by \( L \). Suppose that this is so.

For each \( 0 \leq i \leq q \), we introduce a new unary relation \( X_i \) corresponding (collectively) to the variables with subscript \( i \) in the variable set \( \mathbf{x} \) from Lemma 5.1. Then the remaining clauses of \( \Phi(u, v) \) come directly from the formula \( \Psi(\mathbf{x}) \). So from \( \Psi_V \), we have the following clauses (which are inside the universal quantification over \( u \)): \((X_0(u)), \neg(X_q(u)), \) and, for each \( j \in \{1, \ldots , q\} \), \( \text{IMP}(X_j(u), X_{j-1}(u)) \).

Recall that for each edge \( (u, v) \in E(G) \) with \( u \in V_1(G) \) and \( v \in V_2(G) \), \( \Psi_E(\mathbf{x}) \) contains the clauses \( \text{IMP}(x_{i-1}^u, x_{i-1}^v) \) and \( \text{IMP}(x_i^u, x_i^v) \). In \( \Phi \), these becomes the clauses

\[
L(v) \lor \neg(u \sim v) \lor \text{IMP}(X_{i-1}(u), X_{i-1}(v))
\]

and

\[
L(v) \lor \neg(u \sim v) \lor \text{IMP}(X_j(v), X_{j}(u)).
\]

Finally, we eliminated the possibility of \( \sigma(u) = i \) by adding to \( \Psi_L(\mathbf{x}) \) the clause \( \text{IMP}(x_{i-1}^u, x_{i}^v) \). In \( \Phi \), this becomes \( \text{IMP}(X_{i-1}(u), X_i(v)) \).

The proof of Lemma 5.1 guarantees that the models of \( \Phi \) correspond to the list \( H \)-colorings of \((G, S)\), as desired. Also, each clause of \( \Phi \) uses at most one negated relation and at most one unnegated relation from the set \( \{X_0, \ldots , X_q\} \). Thus, \#\textsc{List-H-Col} is in \#\textsc{RHPI}. \( \square \)

The case when \( H \) is a reflexive proper interval graph is similar, but easier. Let \( q \) be the number of vertices of \( H \). We define the problem in the logical framework using the binary relation \( \sim \) and the unary relations \( U_1, \ldots , U_q \) as follows.

Name. \textsc{List-H-Col}.

Instance. A structure consisting of a finite universe \( V \) and interpretations of the relations in the vocabulary \( \{\sim, U_1, \ldots , U_q\} \).

Output. If the structure consisting of \( V \) and \( \sim \) corresponds to an undirected graph \( G \), then the output is the number of list \( H \)-colorings of \((G, S)\) where, for each \( v \in V \), \( S_v = \{i : v \in U_i\} \) and \( S = \{S_v\} \). Otherwise, the output is 0.
Then the following corollary follows directly from the proof of Lemma 5.1, in the same way as Corollary 5.2.

**Corollary 5.3.** Suppose that $H$ is a connected undirected graph. If $H$ is a reflexive proper interval graph, then the problem $\texttt{#List-H-Col}$ is in $\texttt{#RH}_1$.

### 6. A COUNTEREXAMPLE

The situation that we have studied in this article is characterized by having hard interactions between pairs of adjacent spins (a pair is either allowed or disallowed) and hard constraints on individual spins (again, a spin is either allowed at a particular vertex or disallowed). Our results apply both in the degree-bounded case and in the unbounded-degree case. In the latter case, earlier work treated the situation with weighted interactions and weighted spins. The characterizations derived in these weighted scenarios (see, e.g. Goldberg and Jerrum [2015, Thm 1]) have a similar feel to the trichotomy that we have presented in Theorem 1.1. We may wonder whether, in the unbounded case at least, there is a common generalization. That is, in the unbounded case, does the trichotomy of Goldberg and Jerrum [2015] survive if weights on spins are replaced by lists? The answer is no. There are examples of weighted spin systems with just $q = 2$ spins whose partition function is $\texttt{#SAT}$-hard to approximate with vertex weights but efficiently approximable (in the sense that there is an FPRAS) with lists instead of weights.

Here is one such example. Following Li et al. [2012], define the interaction matrix $A = (a_{ij} : 0 \leq i, j \leq 1)$ by $A = \begin{pmatrix} 0 & 1 \\ 1 & 2 \end{pmatrix}$, and the partition function associated with an instance $G$ by

$$Z_A(G) = \sum_{\sigma : \text{V}(G) \rightarrow \{0,1\}} \prod_{(u,v) \in \text{E}(G)} a_{\sigma(u),\sigma(v)}. \quad (4)$$

This is the partition function of a variant of the independent set model, which, instead of defining the interaction between spin 1 and spin 1 (two vertices that are out of the independent set) to be 1, defines this interaction weight to be 2.

Li et al. [2012, Theorem 21] show that Weitz’s self-avoiding walk algorithm [Weitz 2006] gives an FPTAS for $Z_A(G)$. Also, Weitz’s correlation decay algorithm [Weitz 2006] can accommodate lists. Indeed, the construction of the self-avoiding walk tree relies on being able to “pin” colors at individual vertices. So the partition function (Equation (4)) remains easy to approximate (in the sense that there is an FPTAS) even in the presence of lists. In contrast, the approximation problem becomes $\texttt{#SAT}$-hard if arbitrary weights are allowed. Indeed, by weighting spin 0 at each vertex $u \in \text{V}(G)$ by $2^{d(u)}$, where $d(u)$ is the degree of $u$, we recover the usual independent set partition function, which is $\texttt{#SAT}$-equivalent (Lemma 2.4). (The same fact can be read off from general results in many papers, including Goldberg and Jerrum [2015, Thm 1].) Thus, even in the unbounded case, the dichotomies presented in Goldberg and Jerrum [2015, Thm 1] and Chen et al. [2015, Thm 6] do not hold with lists in place of weights. So even in the unbounded-degree case, it was necessary to explicitly analyze list homomorphisms in order to derive precise characterizations quantifying the problem of approximately counting these.

### APPENDIX

#### A. CHARACTERISATIONS OF HEREDITARY GRAPH CLASSES

In this appendix, we justify the graph-theoretic claims made in Section 2, by reference to the literature.
—Excluded subgraphs for bipartite permutation graphs. This characterization is due to Köhler [1999], building on work of Gallai [1967]. A graph is said to be AT-free if it does not contain a certain kind of induced substructure known as an asteroidal triple. The result we need follows from Köhler [1999, Lemma 1.46] together with the fact that a bipartite graph is AT-free if and only if it is a permutation graph. See the discussion following Köhler [1999, Lemma 1.46] for a statement of the latter fact, together with a proof of the “only if” direction. The “if” direction is not explicitly proved in Köhler [1999] but can be deduced by comparing the excluded subgraphs in Köhler [1999, Fig. 1.6] and Köhler [1999, Fig. 1.16], and noting that all the excluded subgraphs for bipartite AT-free graphs are also excluded subgraphs for bipartite permutation graphs.

—Excluded subgraphs for proper interval graphs. This characterization is due to Wegner [1967] and Roberts [1968]. It follows from combining Roberts [1969, Thm 3(a,b)] with Roberts [1969, Thm 6(a,c)].

—Matrix characterization for bipartite permutation graphs. This characterization follows indirectly from those given by Spinrad et al. [1987]. The equivalence is proved as Lemma 7 of Dyer et al. [2016].

—Matrix characterization for proper interval graphs. Mertzios [2008] shows that an n-vertex graph G is a proper interval graph if and only if it is the intersection graph of a set of n intervals of a restricted form, called the “Stair Normal Interval Representation” (SNIR) of G. These intervals have distinct left endpoints in the set \( \{0, 1, \ldots, n-1\} \); moreover, when the intervals are placed in order of increasing left endpoint, the right endpoints are in monotone nondecreasing order. By Mertzios [2008, Lemma 3], any proper interval graph can be transformed to SNIR form, after which the adjacency matrix (with ones on the diagonal) is in staircase form. Although it is not mentioned explicitly in Mertzios [2008], it is clear that an adjacency matrix (with ones on the diagonal) in staircase form corresponds to an SNIR form by considering the intervals induced by the nonzero elements in the rows of the upper triangular portion of the matrix, and hence to a proper interval graph.
