Recognizing the flat torus among $\text{RCD}^*(0, N)$ spaces via the study of the first cohomology group

Nicola Gigli · Chiara Rigoni

Abstract We prove that if the dimension of the first cohomology group of a $\text{RCD}^*(0, N)$ space is $N$, then the space is a flat torus. This generalizes a classical result due to Bochner to the non-smooth setting and also provides a first example where the study of the cohomology groups in such synthetic framework leads to geometric consequences.

1 Introduction

A classical result due to Bochner concerning manifolds with non-negative Ricci curvature is:

**Theorem 1.1** (Bochner) *Let M be a compact, smooth and connected Riemannian manifold with non-negative Ricci curvature. Then:

(i) The dimension of the first cohomology group is bounded above by the dimension of the manifold.

(ii) If these two dimensions are equal, then M is a flat torus.*

The key observation that leads to (i) is the fact that under the stated assumptions every harmonic 1-form must be parallel and thus determined by its value at any given point \( x \in M \). Since Hodge’s theorem grants that the \( k \)-th cohomology group is isomorphic to the space of harmonic \( k \)-forms, the claim follows.

For (ii), the typical argument starts with the observation that if an \( n \)-dimensional manifold admits \( n \) independent parallel vector fields, then such manifold must be flat. Hence its universal cover, equipped with the pullback of the metric tensor, must be the Euclidean space and the fundamental group \( \pi_1(M) \) acts on it via isometries. Since \( M \sim \mathbb{R}^n/\pi_1(M) \), all is left to show is that \( \pi_1(M) \sim \mathbb{Z}^n \), which can be obtained by ‘soft’ considerations about the structure of the isometries of \( \mathbb{R}^n \) and the fact that \( \mathbb{R}^n/\pi_1(M) \) is, by assumption, compact and smooth (see e.g. [31] for the details).

This paper is about the generalization of the above result to the non-smooth setting of \( \text{RCD}^*(0, N) \) spaces [4,19]. Our starting point is the paper [17] by the first author where a differential calculus on such spaces has been built. Among other things, the vocabulary proposed there allows to speak of vector fields, \( k \)-forms, covariant derivative, Hodge Laplacian and cohomology groups \( H^k_{\text{dR}} \). In particular, a quite natural version of Hodge’s theorem exists in this non-smooth setting, so that we know that cohomology classes are in correspondence with their unique harmonic representative. The basic structure around which the theory is built—and which offers a counterpart for the space of \( L^2 \) section of a normed vector bundle over a smooth manifold—is the one of \( L^2 \)-normed \( L^\infty \)-module.

In searching for an analogous of Theorem 1.1 in the non-smooth setting, one thing to discuss is the notion of dimension. To this aim, let us recall that given a generic \( L^2 \)-normed \( L^\infty \)-module \( \mathcal{M} \) over a space \((X, d, m)\), there exists a unique, up to negligible sets, Borel partition \((E_i)_{i \in \mathbb{N} \cup \{\infty\}}\) of \( X \) such that for every \( i \in \mathbb{N} \) the restriction of \( \mathcal{M} \) to \( E_i \) has dimension \( i \), and for no \( F \subset E_\infty \) with positive measure the restriction of \( \mathcal{M} \) to \( F \) has finite dimension. We consider such partition \((E_i)\) for \( M \) being the tangent module of the space \( X \) and think to the dimension of tangent module on \( E_i \) as the dimension of the space \( X \) on the same set. Hence we shall call \( \dim_{\text{min}}(X) \) (resp. \( \dim_{\text{max}}(X) \)) the minimal (resp. supremum) of indexes \( i \in \mathbb{N} \cup \{\infty\} \) such that \( \mathcal{m}(E_i) > 0 \). Then in [17] the following result has been obtained:

**Theorem 1.2** *Let \((X, d, m)\) be a \( \text{RCD}^*(0, \infty) \) space. Then \( \dim(H^k_{\text{dR}})(X) \leq \dim_{\text{min}}(X) \).

The proof of this fact closely follows the argument for point (i) in Theorem 1.1: every harmonic form is proved to be parallel, so that the dimension of the first cohomology group is bounded by how many independent (co)vector fields we can find on any region of our space. Notice that the compactness assumption is not present because, in the terminology of [17], harmonic forms are by definition in \( L^2 \).
We also point out that a priori such result might be empty, in the sense that without any additional assumption it is very possible that \( \dim_{\text{min}}(X) = \infty \). In fact, the natural assumption on the space \( X \) is not that it is a \( \text{RCD}^*(0, \infty) \) space, but rather a \( \text{RCD}^*(0, N) \) one: given that the number \( N \in [1, \infty) \) represents, in some sense, an upper bound for the dimension of the space we expect it to bound from above \( \dim_{\text{max}}(X) \). This is indeed the case, as it has been proved by Han [25] (see also [23] for an alternative argument):

**Theorem 1.3** Let \( (X, d, m) \) be a \( \text{RCD}^*(K, N) \) space. Then \( \dim_{\text{max}}(X) \leq N \).

Coupling Theorems 1.2 and 1.3 we deduce that:

**Proposition 1.4** Let \( (X, d, m) \) be a \( \text{RCD}^*(0, N) \) space. Then \( \dim(H^k_{\text{dR}})(X) \leq N \).

This statement is a perfect analogue of point (i) in Theorem 1.1. The aim of the present manuscript is to complete this analogy between the smooth and nonsmooth setting by proving:

**Theorem 1.5** Let \( (X, d, m) \) be a \( \text{RCD}^*(0, N) \) space such that \( \dim(H^k_{\text{dR}})(X) = N \) (so that in particular \( N \) is integer). Then it is isomorphic to a flat \( N \)-dimensional torus.

Here ‘isomorphic’ means that there exists a measure preserving isometry from the torus equipped with its Riemannian distance and a constant multiple of the induced volume measure to our space. Unlike the proof of Theorem 1.2 which closely mimics the original one, here we cannot adapt the ‘smooth arguments’ to the current setting: the problem is that it is not known whether \( \text{RCD} \) spaces admit a universal cover or not (there are some results in this direction—see [29]—but it is unclear to us whether they can effectively be used for our current purposes).

We therefore have to pursue a different strategy, the starting steps of our argument being:

- We start studying the flow of an harmonic vector field on our space and, using the fact that in particular such vector field must be parallel and divergence-free, we prove that in accordance with the smooth case such flow is made of measure preserving isometries. Here by ‘flow’ we intend in fact ‘Regular Lagrangian Flow’ in the sense of Ambrosio–Trevisan [7] who adapted to the setting of \( \text{RCD} \) spaces the analogous notion developed by Ambrosio in [1] in connection with the DiPerna–Lions theory [13]. We remark that our result appears to be the first application of Ambrosio–Trevisan theory to vector fields which are not gradients.

- We prove that given two such vector fields \( X, Y \), for their flows \( \text{Fl}_t^X \) and \( \text{Fl}_s^Y \) we have the formula \( \text{Fl}_t^X \circ \text{Fl}_s^Y = \text{Fl}_{t+s}^{X+sY} \) for any \( t, s \in \mathbb{R} \).

- Our assumption on the space \( (X, d, m) \) grants that there are \( N \) independent and orthogonal vector fields \( X_1, \ldots, X_N \) which are parallel and divergence-free, hence we can define the map \( T : X \times \mathbb{R}^N \to X \) by

\[
(x, a_1, \ldots, a_N) \mapsto \text{Fl}_{a_1}^{X_1}(\cdots\text{Fl}_{a_N}^{X_N}(x)).
\]

What previously proved ensures that this map can be seen as an action of \( \mathbb{R}^N \) on \( X \) by isomorphisms.

Analyzing the properties of the map \( T \) will lead to the desired isomorphism with the torus. The hardest part will be the proof of the fact that the action is transitive: to obtain this will require a sharpening of the calculus tools available in the nonsmooth setting and, in particular, we will analyze the structure of the (co)tangent modules on product spaces which we believe to be interesting on its own.
Let us mention that Honda proved in [26] that the dimension of the first cohomology group is upper semicontinuous along a non-collapsing sequence of manifolds with same dimension and a uniform two-sided bound on the Ricci. This result hints at the possibility of obtaining an almost rigidity statement of our theorem in the context of \( \mathbf{RCD} \) spaces, which would informally read as

if a \( \mathbf{RCD} \) space almost fulfills the assumption of Theorem 1.5, then it is \( \text{mGH} \)-close to a flat torus.

In this direction it is worth to emphasize that in the smooth category more is known: as Colding proved in [12] (see also [11]), \( N \)-dimensional manifolds with Ricci \( \geq -\varepsilon \) and first cohomology group of dimension \( N \), not only must be \( \text{mGH} \)-close to the torus, but also diffeomorphic to it for every \( N \geq 2 \). Such differential (and topological) information is out of reach of simple arguments based on the \( \text{mGH} \)-compactness of the class of \( \mathbf{RCD} \) spaces.

We conclude underlying that even in the smooth case, although a lower bound on the Ricci curvature gives information on the first Betti number, higher ones are in general not controlled: see the examples provided by Anderson [9], Sha–Yang [33], Perelman [30] and Menguy [28].

# 2 Preliminaries

To keep the presentation at reasonable length we shall assume the reader familiar with the notions of Sobolev functions on metric measure spaces (introduced in [10], see also the presentations in [3,34]), of differential calculus on such setting (see [15,17]) and with the notion of Regular Lagrangian Flow on metric measure spaces [7,8]. Here we shall only recall a few facts mainly to fix the notation.

For us a metric measure space \((X, d, m)\) will always be a complete and separable metric space equipped with a reference non-negative (and non-zero) Borel measure \( m \) which is finite on bounded sets and with full support, i.e. \( m(\Omega) > 0 \) for every non-empty open set \( \Omega \subset X \). This latter assumption is not really necessary, but simplifies some statements.

## 2.1 \( L^2 \)- and \( L^0 \)-normed modules and basis of differential calculus

**Definition 2.1** \((L^2(X)\)-normed modules) A \( L^2(X) \)-normed \( L^\infty(X) \)-module, or simply a \( L^2(X) \)-normed module, is a structure \((\mathcal{M}, \| \cdot \|, \cdot, | \cdot |)\) where

i) \((\mathcal{M}, \| \cdot \|)\) is a Banach space

ii) \( \cdot \) is a bilinear map from \( L^\infty(X) \times \mathcal{M} \) to \( \mathcal{M} \), called multiplication by \( L^\infty(X) \) functions, such that

\[
\begin{align*}
  f \cdot (g \cdot v) &= (fg) \cdot v, \quad (2.1.1a) \\
  1 \cdot v &= v, \quad (2.1.1b)
\end{align*}
\]

for every \( v \in \mathcal{M} \) and \( f, g \in L^\infty(X) \), where \( 1 \) is the function identically equal to 1.

iii) \( | \cdot | \) is a map from \( \mathcal{M} \) to \( L^2(X) \), called pointwise norm, such that

\[
\begin{align*}
  |v| &\geq 0 \quad \text{ m-a.e.} \quad (2.1.2a) \\
  |fv| &= |f| \, |v| \quad \text{ m-a.e.} \quad (2.1.2b) \\
  \|v\| &= \sqrt{\int |v|^2 \, dm}, \quad (2.1.2c)
\end{align*}
\]
An isomorphism between two $L^2(X)$-normed modules is a linear bijection which preserves the norm, the product with $L^\infty(X)$ functions and the pointwise norm.

**Definition 2.2 (L^0-normed module)** A $L^0$-normed module is a structure $(\mathcal{M}, \tau, \cdot, |\cdot|)$ where:

(i) $\cdot$ is a bilinear map, called multiplication with $L^0$ functions, from $L^0(X) \times \mathcal{M}$ to $\mathcal{M}$ for which (2.1.1a), (2.1.1b) hold for any $f \in L^0(X)$, $v \in \mathcal{M}$,

(ii) $|\cdot| : \mathcal{M} \to L^0(X)$, called pointwise norm, satisfies (2.1.2a) and (2.1.2b) for any $f \in L^0(X)$, $v \in \mathcal{M}$,

(iii) for some Borel partition $(E_i)$ of $X$ into sets of finite $m$-measure, the map

$$d_0(v, w) := \sum_i \frac{1}{2^i m(E_i)} \int_{E_i} \min\{1, |v - w|\} \, dm$$

(2.1.3)

is a complete distance on $\mathcal{M}$ and $\tau$ is the topology induced by it.

An isomorphisms of $L^0$-normed modules is a linear homeomorphism preserving the pointwise norm and the multiplication with $L^0$-functions.

It is readily checked that the choice of the partition $(E_i)$ in (iii) does not affect the completeness of $\mathcal{M}$ nor the topology $\tau$.

**Theorem/Definition 2.3 (L^0 completion of a module)** Let $\mathcal{M}$ be a $L^2$-normed module. Then there exists a unique couple $(\mathcal{M}^0, \imath)$, where $\mathcal{M}^0$ is a $L^0$-normed module and $\imath : \mathcal{M} \to \mathcal{M}^0$ is linear, preserving the pointwise norm and with dense image.

Uniqueness is intended up to unique isomorphism, i.e.: if $(\mathcal{M}^0, \tilde{\imath})$ has the same properties, then there exists a unique isomorphism $\Phi : \mathcal{M}^0 \to \mathcal{M}^0$ such that $\tilde{\imath} = \Phi \circ \imath$.

**2.2 Sobolev spaces for locally integrable objects**

Given a metric measure space $(X, d, m)$, by $L^2_{loc}(X)$ we mean the space of (equivalence classes w.r.t. $m$-a.e. equality of) Borel functions $f : X \to \mathbb{R}$ such that $\chi_B f \in L^2(X)$ for every bounded Borel set $B \subset X$. A curve $t \mapsto f_t \in L^2_{loc}(X)$ will be called continuous (resp. absolutely continuous, Lipschitz, $C^1$) provided for any bounded Borel set $B \subset X$ the curve $t \mapsto \chi_B f_t \in L^2(X)$ is continuous (resp. absolutely continuous, Lipschitz, $C^1$).

Recall that $\pi \in \mathcal{P}(C([0, 1], X))$ is called test plan provided

$$(e_t)_* \pi \leq C m \quad \forall t \in [0, 1], \quad \text{for some } C > 0,$$

$$\int_0^1 |\dot{\gamma}_t|^2 \, dt \, d\pi < \infty.$$

The **Sobolev class** $S^2(X)$ (resp. $S^2_{loc}(X)$) is the space of all Borel functions $f : X \to \mathbb{R}$ for which there exists $G \in L^2(X)$ (resp. $G \in L^2_{loc}(X)$) non-negative, called weak upper gradient, such that

$$\int |f(\gamma_1) - f(\gamma_0)| \, d\pi(\gamma) \leq \int_0^1 G(\gamma_t)|\dot{\gamma}_t| \, dt \, d\pi(\gamma) \quad \text{for every test plan } \pi.$$

It turns out that $f \in S^2_{loc}(X)$ and $G$ is a weak upper gradient if and only if for every test plan $\pi$ we have that for $\pi$-a.e. $\gamma$ the map $t \mapsto f(\gamma_t)$ is in $W^{1,1}(0, 1)$ and

$$\left| \frac{d}{dt} f(\gamma_t) \right| \leq G(\gamma_t)|\dot{\gamma}_t| \quad \text{a.e. } t \in [0, 1].$$

(2.2.1)
From this characterization it follows that there exists a minimal weak upper gradient in the m.a.e. sense: it will be called **minimal weak upper gradient** and denoted by $|Df|$. With a simple cut-off argument, (2.2.1) also shows that $f \in S^2_{\text{loc}}(X)$ if and only if $\eta f \in S^2(X)$ for every $\eta$ Lipschitz and with bounded support.

The **Sobolev space** $W^{1,2}(X)$ (resp. $W^{1,2}_{\text{loc}}(X)$) is defined as $L^2 \cap S^2(X)$ (resp. $L^2_{\text{loc}} \cap S^2_{\text{loc}}(X)$) and again one can check that $f \in W^{1,2}_{\text{loc}}(X)$ if and only if $\eta f \in W^{1,2}(X)$ for every $\eta$ Lipschitz and with bounded support. $W^{1,2}(X)$ is a Banach space when endowed with the norm

$$
\|f\|_{W^{1,2}(X)} := \|f\|_{L^2(X)} + \|Df\|_{L^2(X)}.
$$

(X, d, m) is said **infinitesimally Hilbertian** provided $W^{1,2}(X)$ is a Hilbert space.

Among others, minimal weak upper gradients have the following important locality property:

$$
|Df| = |Dg| \text{ m.a.e. on } \{f = g\} \quad \forall f, g \in S^2_{\text{loc}}(X).
$$

Also, it will be useful to keep in mind that

$$
\forall f \in S^2_{\text{loc}}(X) \text{ there exists } (f_n) \subset S^2(X) \text{ such that } m(X \setminus \bigcup_n \{f = f_n\}) = 0
$$

and for every $n \in \mathbb{N}$ the function $f_n$ is bounded and with bounded support.

Such sequence can be obtained noticing that for $f \in S^2_{\text{loc}}(X)$ the truncated function $(f \wedge (-c)) \vee c$ also belongs to $S^2_{\text{loc}}(X)$ for every $c > 0$ and then proceeding with a cut-off argument.

From the notion of minimal weak upper gradient it is possible to extract the one of differential via the following result:

**Theorem/Definition 2.4** There exists a unique couple $(L^0(T^*X), d)$ with $L^0(T^*X)$ being a $L^0(X)$-normed module and $d : S^2_{\text{loc}}(X) \to L^0(T^*X)$ linear and such that

(i) $|df| = |Df|$ m.a.e. for every $f \in S^2_{\text{loc}}(X)$,

(ii) $L^0(T^*X)$ is generated by $\{df : f \in S^2_{\text{loc}}(X)\}$, i.e. $L^0$-linear combinations of objects of the form $df$ are dense in $L^0(T^*X)$.

Uniqueness is intended up to unique isomorphism, i.e. if $(\mathcal{M}, d')$ is another such couple, then there is a unique isomorphism $\Phi : L^0(T^*X) \to \mathcal{M}$ such that $\Phi(df) = d'f$ for every $f \in S^2_{\text{loc}}(X)$.

Some remarks:

(a) Using the approximation property (2.2.2) one can show that $S^2_{\text{loc}}(X)$ can be replaced with either one of $S^2(X)$, $W^{1,2}(X)$ in the above statement

(b) If one chooses to replace $S^2_{\text{loc}}(X)$ with either $S^2(X)$ of $W^{1,2}(X)$, then it is also possible to replace the $L^0$-normed module with a $L^2$-normed module in the statement and in this case (ii) ‘$L^0$-linear’ should be replaced by ‘$L^\infty$-linear’ (notice that the choice of the module also affects the topology considered, whence the possibility of having two different uniqueness results). The proof is unaltered: compare for instance Theorem 3.2 with the construction of pullback module given in [15,17].

(c) Call $(L^2(T^*X), d)$ the outcome of Theorem 2.4 written for $L^2$-normed modulus and one of the spaces $S^2(X)$, $W^{1,2}(X)$. Then its $L^0$-completion can be fully identified with the couple $(L^0(T^*X), d)$ given by Theorem 2.4 in the sense that: there is a unique linear map $\iota : L^2(T^*X) \to L^0(T^*X)$ sending $df$ to $df$ and preserving the pointwise norm, moreover such map has dense image.

This is trivial to check from the definitions and for this reason we won’t use a distinguished notation for the differential coming from the ‘$L^2$’ formulation of the statement.
Let us now discuss other differentiation operators defined for objects with $L^2_{\text{loc}}$ integrability.

The space of vector fields $L^0(TX)$ is defined as the dual of the $L^0$-normed module $L^0(T^*X)$. Equivalently, it is the $L^0$-completion of the dual $L^2(TX)$ of the $L^2$-normed module $L^2(T^*X)$ (see [15,17]). $L^2_{\text{loc}}(TX) \subset L^0(TX)$ is the space of X’s such that $|X| \in L^2_{\text{loc}}(X)$.

We say that $X \in L^2_{\text{loc}}(TX)$ has divergence in $L^2_{\text{loc}}$, and write $X \in \text{D(div}_{\text{loc}})$, if there exists $h \in L^2_{\text{loc}}(X)$ such that for every $f \in W^{1,2}(X)$ with bounded support it holds

$$\int fh \, \text{dm} = -\int f \, d\langle X \rangle \, \text{dm}.$$ 

In this case we put $\text{div} X := h$.

Let us now assume that $(X, d, m)$ is infinitesimally Hilbertian, so that the pointwise norms in $L^0(T^*X)$, $L^0(TX)$ induce pointwise scalar products. Recall that in this case the modules $L^0(T^*X)$ and $L^0(TX)$ are canonically isomorphic via the Riesz (musical) isomorphism

$$\flat: L^0(TX) \to L^0(T^*X) \quad \text{and} \quad \sharp: L^0(T^*X) \to L^0(TX). \quad (2.2.3)$$

The gradient of a function $f \in W^{1,2}(X)$ is defined as $\nabla f := (df)^\sharp \in L^2_{\text{loc}}(TX)$.

We say that $f \in L^2_{\text{loc}}(X)$ has Laplacian in $L^2_{\text{loc}}$, and write $f \in \text{D}(\Delta_{\text{loc}})$ if there exists $h \in L^2_{\text{loc}}(X)$ such that for every $g \in W^{1,2}(X)$ with bounded support it holds

$$\int gh \, \text{dm} = -\int \langle \nabla f, \nabla g \rangle \, \text{dm}.$$ 

In this case we put $\Delta f := h$. If $f, h \in L^2(X)$ we shall write $f \in D(\Delta)$ instead of $f \in D(\Delta_{\text{loc}})$. It is not hard to check that in this case this notion is equivalent to the more familiar notion of Laplacian as infinitesimal generator of the Dirichlet form

$$E(f) := \begin{cases} 
\frac{1}{2} \int |df|^2 \, \text{dm} & \text{if } f \in W^{1,2}(X), \\
+\infty & \text{otherwise.}
\end{cases}$$

(see [3,4]).

To continue this introduction, we shall now assume that $(X, d, m)$ is a $\text{RCD}(K, \infty)$ space for some $K \in \mathbb{R}$ ([4]); recall that a $\text{RCD}(K, \infty)$ space is an infinitesimally H"{e}bertian metric measure space satisfying the $\text{CD}(K, \infty)$ of Lott–Villani [27] and Sturm [35]. A relevant property of Sobolev functions in relations to the metric of such spaces is the following result, proved in [4] (see also [16,18] for the given formulation):

**Theorem 2.5** Let $(X_1, d_1, m_1)$ and $(X_2, d_2, m_2)$ be two $\text{RCD}(K, \infty)$ spaces with $m_1, m_2$ having full support and $T : X_1 \to X_2$ and $S : X_2 \to X_1$ be Borel maps such that

$$T \circ S = \text{Id}_{X_2} \quad m_2\text{-a.e.}, \quad S \circ T = \text{Id}_{X_1} \quad m_1\text{-a.e.},$$

and

$$T_* m_1 = m_2 \quad E_{X_1}(f \circ T) = E_{X_2}(f) \quad \forall f \in L^2(X_2).$$

Then, up to modifications in a $m_1$-negligible set, $T$ is an isometry.

Recall that the class of test functions (see [32]) is defined as

$$\text{Test}(X) := \{ f \in L^\infty \cap W^{1,2}(X) \cap D(\Delta) : |df| \in L^\infty(X), \Delta f \in W^{1,2}(X) \}.$$
Crucial properties of test functions are that they form an algebra and that $|df|^2 \in W^{1,2}(X)$ for $f \in \text{Test}(X)$ (see [32]). For our discussion, it is also useful to keep in mind that for every $K \subset \Omega \subset X$ with $d(x, y) \geq c$ for some $c > 0$ and every $x \in K$, $y \in \Omega^c$

\begin{equation}
\text{there exists } f \in \text{Test}(X) \text{ with } \supp(f) \subset \Omega \text{ and identically 1 on } K,
\end{equation}

(2.2.4)

see e.g. [6].

With this said, we can define the space $W_{\text{loc}}^{2,2}(X)$ as the space of $f \in W_{\text{loc}}^{1,2}(X)$ for which there exists $A \in L_{\text{loc}}^2((T^*)^\otimes 2 X)$ such that

\[ 2 \int h A(\nabla g, \nabla \tilde{g}) \, dm = - \int (\nabla f, \nabla \tilde{g}) \, (h \nabla g) + (\nabla f, \nabla \hat{g}) \, (h \tilde{\nabla} g) + h(\nabla f, \nabla (\nabla g, \nabla \tilde{g})) \, dm \tag{2.2.5} \]

for every $g, \tilde{g}, h \in \text{Test}(X)$ with bounded support. In this case we call $A$ the \textbf{Hessian} of $f$ and denote it by Hess$(f)$. If $f \in W^{1,2}(X)$ and Hess$(f) \in L^2((T^*)^\otimes 2 X)$ we say that $f \in W^{2,2}(X)$. Noticing that the two sides of (2.2.5) are continuous in $h$ w.r.t. the $W^{1,2}$-norm and using property (2.2.4) it is easy to check that this definition of $W^{2,2}(X)$ coincides with the one given in [17]. Also, $W^{2,2}(X)$ is a separable Hilbert space when endowed the norm

\[ \| f \|_{W^{2,2}(X)} = \| f \|_{L^2(X)} + \| Df \|_{L^2(X)} + \| \text{Hess}(f) \|_{L^2} \]  

We recall (see [17]) that $D(\Delta) \subset W^{2,2}(X)$ and

\[ \int |\text{Hess}(f)|^2_{\text{HS}} \, dm \leq \int |\Delta f|^2 - K|df|^2 \, dm, \tag{2.2.6} \]

so that in particular Test$(X) \subset W^{2,2}(X)$. We then define $H^{2,2}(X)$ as the $W^{2,2}$-closure of Test$(X)$ and similarly $H_{\text{loc}}^{2,2}(X)$ as the $W_{\text{loc}}^{2,2}(X)$-closure of Test$(X)$, i.e.: $f \in H_{\text{loc}}^{2,2}(X) \subset W_{\text{loc}}^{2,2}(X)$ provided there exists a sequence $(f_n) \subset \text{Test}(X)$ such that $f_n, \ldots, f_n, \text{Hess}(f_n)$ converge to $f, \ldots, f_n, \text{Hess}(f)$ in $L_{\text{loc}}^2(X), L_{\text{loc}}^2(TX), L_{\text{loc}}^2((T^*)^\otimes 2 X)$ respectively.

The space of Sobolev vector fields $W_{C_{\text{loc}}}^{1,2}(TX)$ is defined as the space of $X \in L_{\text{loc}}^2(TX)$ for which there is $T \in L^2(T^\otimes 2 X)$ such that

\[ \int h T(\nabla g, \nabla \tilde{g}) \, dm = \int -(X, \nabla \tilde{g}) \, (h \nabla g) + h \text{Hess}(\tilde{g})(X, \nabla g) \, dm \]

for every $h, g, \tilde{g} \in \text{Test}(X)$ with bounded support. In this case we call $T$ the \textbf{covariant derivative} of $X$ and denote it as $\nabla X$. If $|X|, |\nabla X|_{\text{HS}} \in L^2(X)$ we shall say that $X \in W_{C_{\text{loc}}}^{1,2}(TX)$; again, it is not hard to check that this definition of $W_{C_{\text{loc}}}^{1,2}(TX)$ coincides with the one given in [17]. Vector fields of the form $g \nabla f$ for $f, g \in \text{Test}(X)$ are in $W_{C_{\text{loc}}}^{1,2}(TX)$ and the $W_{C_{\text{loc}}}^{1,2}$-closure of the linear span of such vector fields will be denoted $H_{C_{\text{loc}}}^{1,2}(TX)$. The space $H_{C_{\text{loc}}}^{1,2}(TX)$ is then equivalently defined either as the subspace of $L_{\text{loc}}^2(TX)$ made of vectors $X$ of such that $f X \in H_{C_{\text{loc}}}^{1,2}(TX)$ for every $f \in \text{Test}(X)$ with bounded support or as the $W_{C_{\text{loc}}}^{1,2}$-closure of $H_{C_{\text{loc}}}^{1,2}(TX)$, i.e. as the space of vector fields $X \in W_{C_{\text{loc}}}^{1,2}(TX)$ such that there is $(X_n) \subset H_{C_{\text{loc}}}^{1,2}(TX)$ such that $X_n \rightarrow X$ and $\nabla X_n \rightarrow \nabla X$ in $L_{\text{loc}}^2(TX)$ and $L_{\text{loc}}^2(T^\otimes 2 X)$ as $n \rightarrow \infty$.

The ‘local versions’ of the exterior differential, codifferential and Hodge Laplacian are defined in the same way. For us it will be relevant to know that

\[ f \in D(\Delta_{\text{loc}}) \iff df \in D(\Delta_{H, \text{loc}}) \text{ and in this case } df = -\Delta_H \text{ df} \tag{2.2.7} \]
where the minus sign is due to the usual sign convention $\Delta f = -\Delta_H f$; this is a direct consequence of the analogous identity valid in for objects in $D(\Delta), D(\Delta_H)$ and a cut-off argument. Also, we shall use the fact that if $X^b \in D(\Delta_H;_{\text{loc}})$ then $X \in W^{1,2}_{\text{loc}}(TX)$ and the Bochner inequality
\[
\Delta \frac{|X|^2}{2} \geq |\nabla X|^2_{\text{HS}} - \{X^b, \Delta_H X^b\} + K|X|^2
\]
holds in the weak form, i.e.:
\[
\int \frac{|X|^2}{2} \Delta g \, dm \geq \int g \left( |\nabla X|^2_{\text{HS}} - \{X^b, \Delta_H X^b\} + K|X|^2 \right) \, dm
\]
for every $g \in \text{Test}(X)$ non-negative and with bounded support. As before, this follows with a cut-off argument starting with the analogous inequalities valid for the various objects in $L^2$.

We remark that (2.2.7) for a vector field $X \in D(\Delta_H)$ implies, in particular, by integration that
\[
\int |\nabla X|^2_{\text{HS}} \, dm \leq \int \{X^b, \Delta_H X^b\} - K|X|^2 \, dm
\]
and recall that
\[
X^b \in D(\Delta_H) \text{ with } \Delta_H X = 0 \iff \left\{ \begin{array}{l} X^b \in D(\text{d}), \; X \in D(\text{div}) \\ \text{with } \text{d}X^b = 0, \; \text{div} X = 0 \end{array} \right. \quad (2.2.10)
\]
indeed $\iff$ follows from the definition of $\Delta_H$ and $\Rightarrow$ from the identity
\[
\int \{X^b, \Delta_H X^b\} \, dm = \int |\text{d}X^b|^2 + |\text{div} X|^2 \, dm.
\]

### 2.3 Regular Lagrangian flows and continuity equation

Here we recall the concept of Regular Lagrangian Flow of Sobolev vector fields on RCD spaces, which provides a non-smooth analogous of the concept of solution of the ODE
\[
\gamma'_t = X_t(\gamma_t).
\]
This notion has been introduced by Ambrosio [1] in the Euclidean space in the context of DiPerna–Lions theory [13]. Then Ambrosio–Trevisan ([7], see also [8]) showed that theory could be developed in RCD spaces.

**Definition 2.6** (Regular Lagrangian flow) Let $(X_t) \in L^2([0, 1], L^2_{\text{loc}}(TX))$. We say that $\text{Fl}^{(X_t)} : [0, 1] \times X \to X$ is a Regular Lagrangian Flow for $(X_t)$ provided:

(i) There is $C > 0$ such that
\[
\left( \text{Fl}^{(X_t)}_s \right)_s \m \leq C \m \quad \forall s \in [0, 1]. \quad (2.3.1)
\]

(ii) For $\text{m}$-a.e. $x \in X$ the curve $[0, 1] \ni s \mapsto \text{Fl}^{(X_t)}_s (x) \in X$ is continuous and such that $\text{Fl}^{(X_t)}_0 (x) = x$.

(iii) for every $f \in W^{1,2}(X)$ we have: for $\text{m}$-a.e. $x \in X$ the function $s \mapsto f(\text{Fl}^{(X_t)}_s (x))$ belongs to $W^{1,1}(0, 1)$ and it holds
\[
\frac{d}{ds} f(\text{Fl}^{(X_t)}_s (x)) = d f(X_s) (\text{Fl}^{(X_t)}_s (x)) \quad \text{m} \times \mathcal{L}^1_{|[0,1]-a.e.}(x, s). \quad (2.3.2)
\]
We shall also deal with Regular Lagrangian Flows for $X_t \equiv X$: in this case, we shall mainly consider flows defined on the whole $[0, \infty)$ rather than only on $[0, 1]$ and the various statements below should be read with this implicit assumption in mind.

Notice that it is due to property (i) that property (iii) makes sense. Indeed, for given $X_s \in L^2(TX)$ and $f \in W^{1,2}(X)$ the function $df(X_s) \in L^1(X)$ is only defined $m$-a.e., so that (part of) the role of (2.3.1) is to grant that $df(X_s) \circ F_s$ is well defined $m$-a.e. Also, it is known (see Lemmas 7.4 and 9.2 in [7]) that for $m$-a.e. $x$ the curve $s \mapsto \text{Fl}_s^{(X)}(x)$ is absolutely continuous and for its metric speed $|\dot{\text{Fl}}_s^{(X)}(x)|$ we have

$$|\dot{\text{Fl}}_s^{(X)}(x)| = |X_s| \left(\text{Fl}_s^{(X)}(x)\right) \text{ a.e. } s \in [0, 1]. \quad (2.3.3)$$

We shall always work with vector fields $(X_t)$ such that

$$|X_t| \in L^\infty([0, 1], L^\infty(X)). \quad (2.3.4)$$

In this case, a simple property, valid for any $p \in [1, \infty)$, of Regular Lagrangian Flows that we shall occasionally use is the following:

$$f_s \to f \text{ in } L^p(X) \text{ as } s \to 0 \Rightarrow f_s \circ \text{Fl}_s^{(X)} \to f \text{ in } L^p(X) \text{ as } s \to 0. \quad (2.3.5)$$

Indeed, for any Lipschitz function $\tilde{f}$ with bounded support we have

$$\left\| f_s \circ \text{Fl}_s^{(X)} - f \right\|_{L^p} \leq \left\| f_s \circ \text{Fl}_s^{(X)} - \tilde{f} \circ \text{Fl}_s^{(X)} \right\|_{L^p} + \left\| \tilde{f} \circ \text{Fl}_s^{(X)} - \tilde{f} \right\|_{L^p} + \left\| \tilde{f} - f \right\|_{L^p} \quad \text{by (2.3.1)}$$

$$\leq (C^{1/p} + 1) \left\| f_t - \tilde{f} \right\|_{L^p} + \left\| \tilde{f} \circ \text{Fl}_t^{(X)} - \tilde{f} \right\|_{L^p}.$$ 

Since for $m$-a.e. $x \in X$ the curve $s \mapsto \text{Fl}_s^{(X)}(x)$ is Lipschitz and with metric speed bounded above by $\|\|X_t\|\|_{L^\infty(L^\infty)}$, we have

$$\left| \tilde{f} \left(\text{Fl}_t^{X}(x)\right) - \tilde{f}(x) \right| \leq |t| \text{Lip}(\tilde{f}) \|X_t\|_{L^\infty(L^\infty)} \text{ m-a.e. } x \in X,$$

hence letting $t \to 0$ in the above we obtain

$$\lim_{t \to 0} \left\| f_t \circ \text{Fl}_t^{X} - f \right\|_{L^2} \leq (C^{1/p} + 1) \left\| \tilde{f} - f \right\|_{L^p},$$

so that (2.3.5) follows from the arbitrariness of $\tilde{f}$ and the density of Lipschitz functions with bounded support in $L^p(X)$.

We shall mainly use Regular Lagrangian Flows following the via the following characterization:

**Proposition 2.7** Let $(X_t) \in L^2([0, 1], L^2_\text{loc}(TX))$ be such that (2.3.4) holds and $F : [0, 1] \times X \to X$ be a Borel map satisfying (i), (ii) of Definition 2.6. Then the following are equivalent:

(a) (iii) of Definition 2.6 holds, i.e. $F$ is a Regular Lagrangian flow for $(X_t)$.

(b) for every $f \in W^{1,2}(X)$ the map $[0, 1] \ni t \mapsto f \circ F_t \in L^2(X)$ is Lipschitz and for a.e. $t \in [0, 1]$ it holds

$$\lim_{h \to 0} \frac{f \circ F_{t+h} - f \circ F_t}{h} = df(F_t) \circ F_t, \quad (2.3.6)$$

the limit being intended in $L^2(X)$.

(c) for every $f \in W^{1,2}_\text{loc}(X)$ the map $[0, 1] \ni t \mapsto f \circ F_t \in L^2_\text{loc}(X)$ is Lipschitz and for a.e. $t \in [0, 1]$ (2.3.6) holds with the limit being intended in $L^2_\text{loc}$.

Moreover, if these holds and $X_t \equiv X$, then ‘Lipschitz’ in (b), (c) can be replaced by ‘$C^1$', and (2.3.6) holds for every $t \in [0, 1]$. 

© Springer
Proof (a) ⇒ (b) From (2.3.2) and Fubini’s theorem we have that for m-a.e. $x$ and $(\mathcal{L}^{1}_{[0,1]})^{2}$-a.e. $(s_0, s_1)$ it holds

$$\int_{s_0}^{s_1} df(X_s)(\text{Fl}^{(X_s)}(x)) \, ds.$$  

(2.3.7)

By the uniform bound (2.3.4) and (2.3.1) we deduce that $(df(X_s) \circ \text{Fl}^{(X_s)}(x)) \in L^\infty([0,1], L^2(X))$, and thus the Bochner integral $\int_{s_0}^{s_1} df(X_s) \circ \text{Fl}^{(X_s)}(x) \, ds$ is a well defined function in $L^2(X)$ which vary continuously in $s_0, s_1$. By (2.3.5) we also deduce that $s \mapsto f \circ \text{Fl}^{(X_s)}(x) \in L^2(X)$ is continuous, thus from (2.3.7) we obtain that

$$f \circ \text{Fl}^{(X_s)}(x) - f \circ \text{Fl}^{(X_s)} = \int_{s_0}^{s_1} df(X_s) \circ \text{Fl}^{(X_s)}(x) \, ds, \quad \forall s_0, s_1 \in [0,1], \ s_0 < s_1,$$

where the identity is intended in $L^2(X)$ and the integral in the right hand side is the Bochner one. The Lipschitz continuity of $s \mapsto f \circ \text{Fl}^{(X_s)}(x) \in L^2(X)$ and (2.3.6) follow.

(b) ⇒ (c) The assumption (2.3.4) together with (2.3.3) grant finite speed of propagation. Thus for every given bounded set $B \subset X$ the set $B' := \cup_{s \in [0,1]} (\text{Fl}^{(X_s)}(x))^{-1}(B)$ is also bounded and we can find a Lipschitz function $\chi$ with bounded support which is identically 1 on $B'$. Hence for $f \in W^{1,2}_{\text{loc}}(X)$ arbitrary we have $\chi f \in W^{1,2}(X)$ and $(\chi f) \circ \text{Fl}^{(X_s)}(x) = f \circ \text{Fl}^{(X_s)}(x)$ on $B$ for every $s \in [0,1]$. The claim follows from the arbitrariness of $f$ and $B$.

(c) ⇒ (a) By assumption for every bounded set $B \subset X$ we have

$$\chi_B \left( f \circ \text{Fl}^{(X_s)}(x) - f \circ \text{Fl}^{(X_s)} \right) = \int_{s_0}^{s_1} \chi_B df(X_s) \circ \text{Fl}^{(X_s)}(x) \, ds, \quad \forall s_0, s_1 \in [0,1], \ s_0 < s_1$$

and thus from the arbitrariness of $B$ and Fubini’s theorem we conclude that for m-a.e. $x$ it holds

$$\int_{s_0}^{s_1} df(X_s)(\text{Fl}^{(X_s)}(x)) \, ds,$$

2-a.e. $s_0, s_1 \in [0,1], \ s_0 < s_1$.

Applying Lemma 2.1 of [2] we deduce that for m-a.e. $x$ the function $t \mapsto f(\text{Fl}^{(X_s)}(x))$ belongs to $W^{1,1}(0,1)$ and it is now obvious that its distributional derivative is given by $df(X_s)(\text{Fl}^{(X_s)}(x))$, thus concluding the proof.

C^{1} regularity It is sufficient to prove that $s \mapsto df(X_s) \circ \text{Fl}^{(X_s)}(x) \in L^2(X)$ (resp. $L^2_{\text{loc}}$) is continuous for $f \in W^{1,2}(X)$ (resp. $W^{1,2}_{\text{loc}}(X)$). This is a direct consequence of (2.3.5) applied to the functions $s \mapsto df(X_s)$ (resp. $\chi_B df(X)$ for $B \subset X$ Borel and bounded).

With this said, we shall now recall the main result of [7] in the form we will use it:

**Theorem 2.8** Let $(X_t) \in L^2([0,1], W^{1,2}_{C_{\text{loc}}}(TX)) \cap L^\infty([0,1], L^\infty(TX))$ be such that $X_t \in D(\text{div}_{\text{loc}})$ for a.e. $t \in [0,1]$, with

$$\int_{0}^{1} ||\nabla X||_{L^2(X)} + ||\text{div}(X_t)||_{L^2(X)} + ||(\text{div}(X_t))^-||_{L^\infty(X)} \, dt < \infty.$$  

(2.3.8)

Then a Regular Lagrangian Flow $F_s^{(X_t)}$ for $(X_t)$ exists and is unique, in the sense that if $\tilde{f}(X_t)$ is another flow, then for m-a.e. $x \in X$ it holds $F_s(x) = \tilde{f}_s(x)$ for every $s \in [0,1]$. Moreover it holds the quantitative bound

$$\left( F_s^{(X_t)} \right)_* m \leq \exp \left( \int_{0}^{s} ||(\text{div}(X_t))^-||_{L^\infty(X)} \, dt \right) m \quad \forall s \in [0,1].$$  

(2.3.9)
Notice that the uniqueness part of the statement grants in particular that for $X_t$ independent on $t$, say $X_t = X$, the Regular Lagrangian Flow (that in this situation is well defined for any $t \geq 0$) satisfies the semigroup property

$$\text{Fl}^{(X)}_t \circ \text{Fl}^{(X)}_s = \text{Fl}^{(X)}_{t+s} \quad \text{m.a.e.} \quad \forall t, s \geq 0.$$  

(2.3.10)

The uniqueness part of Theorem 2.8 is tightly linked to the uniqueness of solutions of the continuity equation [7,21]:

**Definition 2.9** (Solutions of the continuity equation) Let $t \mapsto \mu_t \in \mathcal{P}(X)$ and $t \mapsto X_t \in L^0(TX)$, $t \in [0, 1]$, be Borel maps. We say that they solve the continuity equation

$$\frac{d}{dt}\mu_t + \text{div}(X_t \mu_t) = 0$$  

(2.3.11)

provided:

(i) $\mu_t \leq Cm$ for every $t \in [0, 1]$ and some $C > 0$,

(ii) we have

$$\int_0^1 \int |X_t|^2 \, d\mu_t \, dt < \infty,$$

(iii) for any $f \in W^{1,2}(X)$ the map $t \mapsto \int f \, d\mu_t$ is absolutely continuous and it holds

$$\frac{d}{dt} \int f \, d\mu_t = \int d\mu_t (X_t) \quad \text{a.e. } t.$$

The following uniqueness result and representation formula has been proved in [7].

**Theorem 2.10** (Uniqueness of solutions of the continuity equation) Let $(X_t)$ be as in Theorem 2.8 and $\tilde{\mu} \in \mathcal{P}(X)$ be such that $\mu_0 \leq Cm$ for some $C > 0$. Then there exists a unique $(\mu_t)$ such that $(\mu_t, X_t)$ solves the continuity equation (2.3.11) in the sense of Definition 2.9 and for which $\mu_0 = \tilde{\mu}$. Moreover, such $(\mu_t)$ is given by

$$\mu_s = \left(\text{Fl}^{(X)}_s\right)^\ast \tilde{\mu} \quad \forall s \in [0, 1].$$

3 Calculus tools

3.1 Local bounded compression/deformation

Here we shall extend the constructions of pullback module and pullback of 1-forms provided in [17] (see also [15]) to maps which are locally of bounded compression/deformation. For this, it is technically convenient to work with $L^0$-normed modules rather than with $L^2$-normed ones.

3.1.1 Pullback module through a map of local bounded compression

**Definition 3.1** (Maps of local bounded compression) Let $(X_1, m_1)$ and $(X_2, m_2)$ be two $\sigma$-finite measured spaces. We say that $\varphi : X_1 \to X_2$ is a map of local bounded compression provided for every $B \subset \mathcal{B}(X_1)$ with $m_1(B) < +\infty$ there exists a constant $C_B \geq 0$ such that

$$\varphi_*(m_{1\mid_B}) \leq C_B m_2.$$  

(3.1.1)
**Theorem/Definition 3.2** Let \((X_1, m_1)\) and \((X_2, m_2)\) be two \(\sigma\)-finite measured spaces, \(\varphi : X_1 \rightarrow X_2\) be of local bounded compression and \(\mathcal{M}\) a \(L^0(X_2)\)-normed module. Then there exists a unique couple \([(\varphi^*, \mathcal{M})]\) where \([\varphi^*] : \mathcal{M} \rightarrow [\varphi^*]\) is a linear map such that:

1. \(||[\varphi^*]| v| = |v| \circ \varphi m_1\text{-a.e. for every } v \in \mathcal{M},\)
2. \([\varphi^*] \mathcal{M}\) is generated by \(\{|[\varphi^*]| v : v \in \mathcal{M}\}\).

Uniqueness is intended up to unique isomorphism, i.e.: if \([(\varphi^*, \mathcal{M}), [\tilde{\varphi}^*]]\) is another such couple, then there exists a unique isomorphism \(\Phi : [\varphi^*] \mathcal{M} \rightarrow [\tilde{\varphi}^*] \mathcal{M}\) such that \([\tilde{\varphi}^*] = [\varphi^*] \circ \Phi\).

**Proof**

**Existence** We define the ‘pre-pullback’ set \(Ppb\) as

\[
Ppb := \{(v_i, A_i)_{i=1,...,n} : n \in \mathbb{N}, \ (A_i) \subset \mathcal{B}(X_1)\text{ is a partition of } X_1 \text{ and } v_i \in \mathcal{M} \ \forall i = 1, \ldots, n\}
\]

and an equivalence relation on it by declaring \((v_i, A_i) \sim (w_j, B_j)\) provided

\[
|v_i - w_j| \circ \varphi = 0 \ \text{m}_1\text{-a.e. on } A_i \cap B_j \ \forall i, j.
\]

It is readily verified that it is actually an equivalence relation on \(Ppb\): we shall denote by \([\{(v_i, A_i)\}]\) the equivalence class of \((v_i, A_i)\).

We endow \(Ppb/\sim\) with a vector space structure by putting

\[
[(v_i, A_i)] + [(w_j, B_j)] := [(v_i + w_j, A_i \cap B_j)]
\]

\[
\lambda[(v_i, A_i)] := [\lambda v_i, A_i]
\]

for every \([(v_i, A_i)], [(w_j, B_j)] \in Ppb/\sim\) and \(\lambda \in \mathbb{R}\). Notice that these are well defined. Moreover, we define a pointwise norm on \(Ppb/\sim\) and a multiplication with simple functions by putting

\[
||[\{v_i, A_i\}]|| := \sum_i \chi_{A_i} |v_i| \circ \varphi
\]

\[
g([v_i, A_i]) := [(\alpha_j v_i, A_i \cap E_j)] \text{ for } g = \sum_j \alpha_j \chi_{E_j}.
\]

Again, these are easily seen to be well defined; then we fix a partition \((E_i) \subset \mathcal{B}(X_1)\) of \(X_1\) made of sets of finite \(m_1\)-measure and define the distance \(d_0\) on \(Ppb/\sim\) as

\[
d_0([(v_i, A_i)], [(w_j, B_j)]) := \sum_{k \in \mathbb{N}} \frac{1}{2k} \int_{E_k} ||[v_i, A_i]] - [(w_j, B_j)]|| \, dm_1.
\]

We then define the space \([\varphi^*] \mathcal{M}\) as the completion of \((Ppb/\sim, d_0)\), equipped with the induced topology and the pullback map \([\varphi^*] : \mathcal{M} \rightarrow [\varphi^*] \mathcal{M}\) as \([\varphi^*]v := [v, X_1]\). The (in)equalities

\[
||[v_i + w_j, A_i \cap B_j]]|| \leq ||[v_i, A_i]] + ||[w_j, B_j]]||,
\]

\[
|\lambda[[v_i, A_i]]| = |\lambda||[v_i, A_i]]||,
\]

\[
g[[v_i, A_i]] = |g||[v_i, A_i]]||,
\]

valid \(m_1\text{-a.e. for every } [[v_i, A_i]], [[w_j, B_j]] \in Ppb/\sim, \lambda \in \mathbb{R}\) and simple function \(g\) grant that the vector space structure, the pointwise norm and the multiplication by simple functions
can all be extended by continuity to the whole $[\phi^*]\.M$ and it is then clear with these operations such space is a $L^0$-normed module.

Property (1) then follows by the very definitions of pullback map and pointwise norm, while property (2) from the fact that $\text{Ppb}/_1$ is dense in $[\phi^*]\.M$ and the typical element $[v_i, A_i]$ of $\text{Ppb}/_1$ is equal to $\sum_i A_i [\phi^*]v_i$.

**Uniqueness** The requirement for $\Phi: [\phi^*]\.M \to [\phi^*]\.M$ to be $L^0(X_i)$-linear and such that $[\tilde{\phi}^*] = [\phi^*] \circ \Phi$ force the definition

$$\Phi(V) := \sum_i A_i [\tilde{\phi}^*]v_i \quad \text{for} \quad V = \sum_i A_i [\phi^*]v_i. \quad (3.1.2)$$

The identity

$$|\Phi(V)| = \sum_i A_i |[\tilde{\phi}^*]v_i| = \sum_i A_i |[\phi^*]v_i| = |V|$$

shows in particular that the definition of $\Phi(V)$ is well-posed, i.e. it depends only on $V$ and not on the particular way to represent it as sum. It also shows that it preserves the pointwise norm and thus it is continuous. Since the space of $V$'s of the form $\sum_i A_i [\phi^*]v_i$ is dense in $[\phi^*]\.M$ (property (2) for $[\phi^*]\.M$), such $\Phi$ can be uniquely extended to a continuous map on the whole $[\phi^*]\.M$ and such extension is clearly linear, continuous, and preserves the pointwise norm. By definition, it also holds $\Phi(gV) = g\Phi(V)$ for $g$ simple and $V = \sum_i A_i [\phi^*]v_i$ and thus by approximation we see that the same holds for general $g \in L^0(X_1)$ and $V \in [\phi^*]\.M$.

It remains to show that the image of $\Phi$ is the whole $[\phi^*]\.M$: this follows from the fact that elements of the form $\sum_i A_i [\phi^*]v_i$, which by definition are in the image of $\Phi$, are dense in $[\phi^*]\.M$ by property (2) for $[\phi^*]\.M$. $\square$

We shall now provide an explicit representation of such pullback module in the case when $\phi$ is a projection.

Thus let $(X_1, m_1)$ and $(X_2, m_2)$ be two $\sigma$-finite measured spaces and let $\.M$ be a $L^0(X_1)$-module over $X_1$.

We shall denote by $L^0(X_2, \mathcal{M})$ the space of (equivalence classes up to $m_2$-a.e. equality of) strongly measurable functions (=Borel and essentially separably valued, the latter meaning that except for a negligible set the function take values in a separable subspace) from $X_2$ to $\.M$ and claim that such space canonically carries the structure of $L^0(X_1 \times X_2)$-normed module. The multiplication of an element in $L^0(X_2, \mathcal{M})$ by a function $f \in L^0(X_1 \times X_2)$ is defined as the map $X_2 \ni x_2 \mapsto f(\cdot, x_2) \cdot v(\cdot, x_2) \in \mathcal{M}$. By approximating $f$ in $L^0(X_1 \times X_2)$ with functions having finite range it is easy to check that $x_2 \mapsto f(\cdot, x_2) \cdot v(\cdot, x_2)$ has separable range if $x_2 \mapsto v(\cdot, x_2)$ does, so that this definition is well posed. Similarly, the pointwise norm of $v \in L^0(X_2, \mathcal{M})$ is obtained composing the map $x_2 \mapsto v(\cdot, x_2) \in \mathcal{M}$ with the pointwise norm on $\.M$, thus providing an element of $L^0(X_2, L^0(X_1)) \sim L^0(X_1 \times X_2)$. Finally, we use such pointwise norm to define the topology of $L^0(X_2, \mathcal{M})$ as in point (ii) of Definition 2.2.

It is not hard to check that sequences converging in this topology are made of maps $v_n(\cdot, x_2)$ which are $m_2$-a.e. converging and that with these definitions $L^0(X_2, \mathcal{M})$ is indeed a $L^0(X_1 \times X_2)$-normed module.

In what will come next, we shall often implicitly use the following identification:

**Proposition 3.3** ($[\pi_1]^*\.M$ is isomorphic to $L^0(X_2, \mathcal{M})$) Let $(X_1, m_1)$ and $(X_2, m_2)$ be two $\sigma$-finite measured spaces, $\.M$ a $L^0(X_1)$-module over $X_1$ and $\pi_1: X_1 \times X_2 \to X_1$ the canonical projection.
Then there exists a unique isomorphism from $[\pi_1^*](\mathcal{M})$ to $L^0(X_2, \mathcal{M})$ which for every $v \in \mathcal{M}$ sends $[\pi_1^*]v$ to the function in $L^0(X_2, \mathcal{M})$ constantly equal to $v$.

Proof For $v \in \mathcal{M}$ let $\hat{v} \in L^0(X_2, \mathcal{M})$ be the function constantly equal to $v$. It is clear that $|\hat{v}| = |v| \circ \pi_1^*m_1 \times m_2$-a.e.. Moreover, from the fact that functions in $L^0(X_2, \mathcal{M})$ are essentially separably valued it follows by standard means in vector-space integration that $\{\hat{v} : v \in \mathcal{M}\}$ generate the whole $L^0(X_2, \mathcal{M})$.

The conclusion comes from Theorem 3.2. \(\square\)

3.1.2 Localized pullback of 1-forms

**Definition 3.4** (Maps of local bounded deformation) Let $(X_1, d_1, m_1)$ and $(X_2, d_2, m_2)$ be two metric measure spaces. We say that a map $\varphi : X_1 \rightarrow X_2$ is of local bounded deformation if for every bounded set $B \subset X_1$ there are constants $L(B), C(B) > 0$ such that:

\[
\varphi \text{ is } L(B)\text{-Lipschitz on } B \quad \varphi_*(m_1|_B) \leq C(B)m_2.
\]

Recalling that the local Lipschitz constant $\text{lip} \varphi : X_1 \rightarrow [0, \infty]$ is defined as

\[
\text{lip} \varphi(x) := \lim_{y \rightarrow x} \frac{d_2(\varphi(x), \varphi(y))}{d_1(x, y)}
\]

if $x$ is not isolated, 0 otherwise, we have the following simple statement:

**Proposition 3.5** Let $(X_1, d_1, m_1)$ and $(X_2, d_2, m_2)$ be two metric measure spaces and $\varphi : X_1 \rightarrow X_2$ be a map of local bounded deformation. Then for any $f \in \mathcal{S}_\text{loc}^2(X_2)$, we have $f \circ \varphi \in \mathcal{S}_\text{loc}^2(X_1)$ and

\[
|d(f \circ \varphi)| \leq \text{lip} \varphi |df| \circ \varphi, \quad \text{m}_1\text{-a.e.} \quad (3.1.3)
\]

Proof Fix a point $\bar{x} \in X_1$, let $A_n \subset C([0, 1], X_1)$ be defined as

\[
A_n := \{\gamma \in C([0, 1], X_1) : \gamma_t \in B_n(\bar{x}) \ \forall t \in [0, 1]\}
\]

and notice that $\cup_n A_n = C([0, 1], X_1)$. Now let $\pi$ be a test plan on $X_1$ and notice that for $n$ sufficiently large the measure $\pi_n := \pi(A_n)^{-1}\pi|_{A_n}$ is well defined and a test plan. By construction we have

\[
(e_t)_*\varphi_*\pi_n \leq \pi(A_n)^{-1}C(B_n(\bar{x}))C(\pi)m_2 \quad \forall t \in [0, 1],
\]

where $C(\pi)$ is such that $(e_t)_*\pi \leq C(\pi)m_1$ for every $t \in [0, 1]$, and taking into account the trivial bound

\[
\{\text{metric speed of } t \mapsto \varphi(\gamma_t)\} \leq \text{lip} \varphi(\gamma_t)|\dot{\gamma}_t| \quad a.e. \ t \quad (3.1.4)
\]

we also have

\[
\int_0^1 |\dot{\gamma}_t|^2 dt \ d\varphi_*\pi_n(\gamma) \leq \pi(A_n)^{-1}L^2(B_n(\bar{x})) \int_0^1 |\dot{\gamma}_t|^2 dt \ d\pi_n(\gamma).
\]

Hence $\varphi_*\pi_n$ is a test plan on $X_2$ and thus for $\varphi_*\pi_n$-a.e. $\tilde{\gamma}$ we have that $t \mapsto f(\tilde{\gamma})$ is in $W^{1, 1}(0, 1)$ with

\[
\left| \frac{d}{dt} f(\tilde{\gamma}) \right| \leq |\dot{\gamma}_t||df|(\tilde{\gamma}_t).
\]
Recalling (3.1.4) this means that for $\pi_n$-a.e. $\gamma$ the map $t \mapsto f(\varphi(\gamma_t))$ belongs to $W^{1,1}(0, 1)$ with
\[
\frac{d}{dt} f(\varphi(\gamma_t)) \leq \text{lip } \varphi(\gamma_t) |\dot{\gamma}_t| |df| \varphi(\gamma_t)). \quad (3.1.5)
\]
Being this true for every $n \in \mathbb{N}$ sufficiently large, (3.1.5) holds also for $\pi$-a.e. $\gamma$ and since $\text{lip } |df| \circ \varphi \in L^2_{\text{loc}}(X_1)$, by the characterization (2.2.1) of Sobolev functions the proof is completed. \qed

**Theorem/Definition 3.6** (Pullback of 1-forms) Let $(X_1, d_1, m_1)$ and $(X_2, d_2, m_2)$ be two metric measure spaces and $\varphi : X_1 \to X_2$ be a map of local bounded deformation.

Then there exists a unique linear and continuous map $\varphi^* : L^0(T^*X_2) \to L^0(T^*X_1)$ such that
\[
\varphi^*(df) = df(\circ \varphi), \quad \forall f \in S^2_{\text{loc}}(X_2),
\]
and
\[
\varphi^*(g \omega) = g \circ \varphi \varphi^* \omega, \quad \forall g \in L^0(X_2), \quad \omega \in L^0(T^*X_2),
\]
\[
(3.1.6)
\]
and such map satisfies
\[
|\varphi^* \omega| \leq \text{lip } \varphi |\omega| \circ \varphi \quad \text{m}_1\text{-a.e.}, \quad \forall \omega \in L^0(T^*X_2). \quad (3.1.7)
\]

**Proof** The requirements (3.1.6) force the definition
\[
\varphi^* \omega := \sum_i \chi_{\varphi^{-1}(E_i)} d(f_i \circ \varphi) \quad \text{for } \omega = \sum_i \chi_{E_i} d f_i, \quad (3.1.8)
\]
for $(E_i)$ finite Borel partition of $X_2$ and $(f_i) \subset S^2_{\text{loc}}(X_2)$. The bound
\[
|\varphi^* \omega| = \sum_i \chi_{\varphi^{-1}(E_i)}|d(f_i \circ \varphi)| \leq \text{lip } \varphi \sum_i \chi_{E_i} \circ \varphi |d f_i| \circ \varphi = \text{lip } \varphi |\omega| \circ \varphi, \quad (3.1.9)
\]
grants both that the definition of $\varphi^* \omega$ is well-posed (i.e. its value depends only on $\omega$ and not in how it is written as $\sum_i \chi_{E_i} d f_i$) and that $\varphi^*$ is continuous from the space of $\omega$’s as in (3.1.8) with the $L^0(T^*X_2)$-topology to $L^0(T^*X_1)$. Since the class of such $\omega$’s is dense in $L^0(T^*X_2)$, we can uniquely extend $\varphi^*$ to a continuous map from $L^0(T^*X_2)$ to $L^0(T^*X_1)$.

The resulting extension satisfies the first in (3.1.6) by definition, while (3.1.7) comes from (3.1.9). The second in (3.1.6) for simple functions $g$ is a direct consequence of the definition (3.1.8), then the general case follows by approximation. Thus existence is proved; uniqueness follows from the fact that the construction has been forced by the requirements in the statement. \qed

### 3.2 Calculus on product spaces

#### 3.2.1 Cotangent module and product of spaces

Let $(X_1, d_1, m_1)$ and $(X_2, d_2, m_2)$ be two metric measure spaces. Aim of this section is to relate the cotangent modules of $X_1, X_2$ to that of the product space $X_1 \times X_2$, which will be always implicitly endowed with the product measure and the distance
\[
(d_1 \otimes d_2)^2((x_1, x_2), (y_1, y_2)) := d_1^2(x_1, y_1) + d_2^2(x_2, y_2).
\]
Let $\pi_i : X_1 \times X_2 \to X_i, i = 1, 2$ be the canonical projections, observe that they are of local bounded deformation and recall from Proposition 3.3 and the discussion before it that
Proposition 3.7 Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be two metric measure spaces. Then there exists a unique \(L^0(X_1 \times X_2)\)-linear and continuous map \(\Phi_1 : L^0(X_2, L^0(T^*X_1)) \rightarrow L^0(T^*(X_1 \times X_2))\) such that

\[
\Phi_1(\hat{d}g) = d(g \circ \pi_1) \quad \forall g \in S^2_{\text{loc}}(X_1),
\]

where \(\hat{d}g : X_2 \rightarrow L^0(T^*X_1)\) is the function identically equal to \(dg\). Such map preserves the pointwise norm.

Similarly, there is a unique \(L^0(X_1 \times X_2)\)-linear and continuous map \(\Phi_2 : L^0(X_1, L^0(T^*X_2)) \rightarrow L^0(T^*(X_1 \times X_2))\) such that

\[
\Phi_2(\hat{d}h) = d(h \circ \pi_1) \quad \forall h \in S^2_{\text{loc}}(X_2),
\]

where \(\hat{d}h : X_1 \rightarrow L^0(T^*X_2)\) is the function identically equal to \(dh\), and such map preserves the pointwise norm.

Proof We shall prove the claims for \(\Phi_1\), as then the ones for \(\Phi_2\) follow by symmetry. The required \(L^0\)-linearity and (3.2.1) force the definition

\[
\Phi_1(W) := \sum_{i,j} \chi_{A_i} \circ \pi_1 \chi_{B_j} \circ \pi_2 d(g_{i,j} \circ \pi_1) \quad \text{for} \quad W = \sum_{i,j} \chi_{B_j} (\chi_{A_i} dg_{i,j})
\]

(3.2.2)

where \((A_i), (B_j)\) are finite Borel partitions of \(X_1, X_2\) respectively and \((g_{i,j}) \subset S^2_{\text{loc}}(X_1)\).

Since \(\pi_1\) is 1-Lipschitz we have

\[
|\Phi_1(W)| = \sum_{i} \chi_{B_i} \circ \pi_2 |d(g_i \circ \pi_1)| \leq \sum_{i} \chi_{B_i} \circ \pi_2 |dg_i| \circ \pi_1 = |W|
\]

(3.2.3)

which shows both that (3.2.2) provides a good definition for \(\Phi_1(W)\), in the sense that \(\Phi_1(W)\) depends only on \(W\) and not on the way we write it as \(\sum_{i,j} \chi_{B_j} (\chi_{A_i} dg_{i,j})\), and that it is continuous. The definition also ensures that \(\Phi_1(fW) = f\Phi_1(W)\) for \(f \in L^0(X_1 \times X_2)\) of the form \(\sum_{i,j} \alpha_{i,j} \chi_{A_i} \chi_{B_j}\) for \((A_i), (B_j)\) finite Borel partitions of \(X_1, X_2\) respectively and \((\alpha_{i,j}) \subset \mathbb{R}\).

Since these functions are dense in \(L^0(X_1 \times X_2)\) and \(W\)'s as in (3.2.2) are dense in \(L^0(X_1, L^0(T^*X_2))\), this is enough to show existence and uniqueness of a \(L^0\)-linear and continuous \(\Phi_1\) for which (3.2.1) holds and, from (3.2.3), that for such \(\Phi_1\) we have

\[
|\Phi_1(W)| \leq |W| \quad m_1 \times m_2\text{-a.e.}
\]

(3.2.4)

Thus to conclude it is sufficient to show that equality holds and, by the very same arguments just given, to this aim it is sufficient to show that

\[
|dg| \circ \pi_1 = |d(g \circ \pi_1)| \quad m_1 \times m_2\text{-a.e.} \quad \forall g \in S^2_{\text{loc}}(X_1).
\]

(3.2.5)

It is now convenient to consider the map

\[
T : C([0, 1], X_1) \times X_2 \rightarrow C([0, 1], X_1 \times X_2) \quad \begin{cases} t \mapsto \gamma_t(x_2) \mapsto t \mapsto (\gamma_t, x_2). \end{cases}
\]

Notice that

\[
\text{for any } x_2 \in X_2 \text{ the speed of } T(\gamma, x_2) \text{ is equal to the speed of } \gamma \text{ for a.e. } t
\]

(3.2.6)
and fix \( \mu \in \mathcal{P}(X_2) \) such that \( \mu \leq \tilde{C}m_2 \) for some \( \tilde{C} > 0 \). Then for an arbitrary test plan \( \pi \) on \( X_1 \) define
\[
\tilde{\pi} := T_\pi(\mu \times \pi) \in \mathcal{P}(C([0,1], X_1 \times X_2))
\]
and observe that \( \tilde{\pi} \) is a test plan on \( X_1 \times X_2 \). Hence for any \( g \in C^{2,0}(X_1) \) we have
\[
\int |g \circ e_1 - g \circ e_0| \, d\pi = \int |g \circ \pi_1 \circ e_1 - g \circ \pi_1 \circ e_0| \, d\tilde{\pi}
\]
\[
\leq \int_0^1 \int |d(g \circ \pi_1)(\tilde{\gamma}_t)| \tilde{\gamma}_t^\prime \, d\tilde{\pi}(\tilde{\gamma}) \, dt
\]
by (3.2.6)
\[
= \int_0^1 \int \left( \left( \int |d(g \circ \pi_1)(T(\gamma, x_2))| \, d\mu(x_2) \right) |\tilde{\gamma}_t^\prime| \, d\pi(\gamma) \, dt \right)
\]
so that the arbitrariness of \( \pi \) gives that the function \( \int |d(g \circ \pi_1)(\cdot, x_2)| \, d\mu(x_2) \) is a weak upper gradient of \( g \). Therefore for \( m_1 \)-a.e. \( x_1 \) we have
\[
|dg|(x_1) \leq \int |d(g \circ \pi_1)(x_1, x_2)| \, d\mu(x_2) \overset{\text{(3.1.3)}}{\leq} \int |dg| \circ \pi_1(x_1, x_2) \, d\mu(x_2) = |dg|(x_1).
\]
Hence the inequalities are equalities and the arbitrariness of \( \mu \) gives (3.2.5).

It seems hard to obtain any further relation between the cotangent modules in full generality, for this reason from now on we shall make two structural assumptions. In the following, for any function \( f(x_1, x_2) \) on the product space \( X_1 \times X_2 \), we define \( f^{x_1}(\cdot) := f(x_1, \cdot) \) and, similarly, \( f_{x_2}(\cdot) := f(\cdot, x_2) \).

**Definition 3.8** *(Tensorization of the Cheeger energy)* We say that two metric measure spaces \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) have the property of tensorization of the Cheeger energy provided for any \( f \in L^2(X_1 \times X_2) \) the following holds: \( f \in W^{1,2}(X_1 \times X_2) \) if and only if
\[
- f^{x_1} \in W^{1,2}(X_2) \text{ for } m_1 \text{-a.e. } x_1 \in X_1 \text{ and } \iint |df^{x_1}|^2 \, dm_1(x_1) < \infty
- f_{x_2} \in W^{1,2}(X_1) \text{ for } m_2 \text{-a.e. } x_2 \in X_2 \text{ with } \iint |df_{x_2}|^2 \, dm_2(x_2) < \infty
\]
and in this case it holds
\[
|df|^2(x_1, x_2) = |df^{x_1}|^2(x_2) + |df_{x_2}|^2(x_1) \quad m_1 \times m_2 \text{-a.e. } (x_1, x_2). \quad (3.2.7)
\]
Notice that for \( g \in L^\infty \cap W^{1,2}(X_1) \) and \( h \in L^\infty \cap W^{1,2}(X_2) \), both with bounded support, the function \( g \circ \pi_1 h \circ \pi_2 \) has bounded support and is in \( L^\infty \cap W^{1,2}(X_1 \times X_2) \), its differential being given by
\[
d(g \circ \pi_1 h \circ \pi_2) = g \circ \pi_1 d(h \circ \pi_2) + h \circ \pi_2 d(g \circ \pi_1). \quad (3.2.8)
\]

**Definition 3.9** *(Density of the product algebra)* We say that two metric measure spaces \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) have the property of density of product algebra if the set
\[
\mathcal{A} := \left\{ \sum_{j=1}^n g_j \circ \pi_1 h_j \circ \pi_2 : n \in \mathbb{N}, \ g_j \in L^\infty \cap W^{1,2}(X_1) \text{ has bounded support, } \ h_j \in L^\infty \cap W^{1,2}(X_2) \text{ has bounded support } \forall j = 1, \ldots, n \right\}
\]
is dense in \( W^{1,2}(X_1 \times X_2) \) in the strong topology of \( W^{1,2}(X_1 \times X_2) \).

From now on we will always assume the following:
Assumption 3.10 \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) are two metric measure spaces for which both the tensorization of Cheeger energy and the density of the product algebra hold.

It is worth to underline that no couple of spaces \(X_1, X_2\) are known for which Assumption 3.10 does not hold. On the other hand, it is unclear if that holds in full generality. The first results about the tensorization of Cheeger energies being given in [4] for the cases of two \(\text{RCD}\) spaces with finite mass, for our purposes the following result covers the cases of interest:

Proposition 3.11 Let \((X_1, d_1, m_1)\) be a \(\text{RCD}(K, \infty)\) spaces and let \(X_2\) be the Euclidean space \(\mathbb{R}^N\) equipped with the Euclidean distance and the Lebesgue measure.

Then both the tensorization of the Cheeger energy and the density of the product algebra hold.

Proof In [20] it has been proved that for arbitrary \((X_1, d_1, m_1)\) and for \(X_2 = \mathbb{R}\) the tensorization of the Cheeger energy holds and the algebra \(\mathcal{A}\) is dense in energy, i.e.: for any \(f \in W^{1,2}(X_1 \times \mathbb{R})\) there is \((f_n) \subset \mathcal{A}\) such that \(f_n \rightharpoonup f\) and \(|d f_n| \rightharpoonup |d f|\) in \(L^2(X_1 \times \mathbb{R})\).

If \((X_1, d_1, m_1)\) is infinitesimally Hilbertian (which is the case for \(\text{RCD}\) spaces), then the tensorization of the Cheeger energy ensures that \(W^{1,2}(X_1 \times \mathbb{R})\) is a Hilbert space, so that the uniform convexity of the norm grants that convergence in energy implies strong \(W^{1,2}\)-convergence.

Thus the thesis is true for \(X_2 = \mathbb{R}\). The general case follows by a simple induction argument.

With this said, we shall now continue the investigation of the relation between cotangent modules and products of spaces. We start with the following result; notice that the density of the product algebra is used to show that for \(f \in S^2_{\text{loc}}(X_1 \times X_2)\) the map \(x_2 \mapsto d f_{x_2} \in L^0(T^*X_1)\) is essentially separably valued.

Lemma 3.12 Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be two metric measure spaces satisfying Assumption 3.10.

Then for every \(f \in S^2_{\text{loc}}(X_1 \times X_2)\) we have that \(f_{x_2} \in S^2_{\text{loc}}(X_1)\) for \(m_2\)-a.e. \(x_2\) and the map \(x_2 \mapsto d f_{x_2}\) belongs to \(L^0(X_2, L^0(T^*X_1))\). Moreover, for \((f_n) \subset S^2_{\text{loc}}(X_1 \times X_2)\) we have

\[
|d f_n| \rightharpoonup |d f| \quad \text{in } L^0(T^*(X_1 \times X_2)) \quad \Rightarrow \quad d(f_n) \rightharpoonup d f \quad \text{in } L^0(X_2, L^0(T^*X_1)).
\]

(3.2.10)

Similarly for the roles of \(X_1\) and \(X_2\) inverted. Finally, the identity (3.2.7) holds for any \(f \in S^2_{\text{loc}}(X_1 \times X_2)\).

Proof Let \(f = g \circ \pi_1 \circ h \circ \pi_2\) for some \(g \in L^\infty \cap W^{1,2}(X_1)\) and \(h \in L^\infty \cap W^{1,2}(X_2)\) with bounded supports and notice that \(d f_{x_2} = h(x_2) \, d g\) for every \(x_2 \in X_2\). Hence \(x_2 \mapsto d f_{x_2} \in L^2(X_2, L^2(T^*X_1))\).

By linearity, the same holds for a generic \(f \in \mathcal{A}\). Now notice that for an arbitrary \(f \in W^{1,2}(X_1 \times X_2)\), the identity (3.2.7) yields

\[
|d f_{x_2}|^2(x_1) \leq |d f|^2(x_1, x_2) \quad m_1 \times m_2\text{-a.e. } (x_1, x_2),
\]

(3.2.11)

and thus

\[
\|d f - d \tilde{f}\|_{L^2(X_2, L^2(T^*X_1))} \leq \| f - \tilde{f}\|_{W^{1,2}(X_1 \times X_2)}.
\]

(3.2.12)

Hence for \(f \in W^{1,2}(X_1 \times X_2)\) arbitrary, using the density of the product algebra we can find \((f_n) \subset \mathcal{A} W^{1,2}\)-converging to \(f\), so that from (3.2.12) we see that \(d f \in L^2(X_2, L^2(T^*X_1))\).

We now prove (3.2.11) for \(f \in S^2_{\text{loc}}(X_1 \times X_2)\) thanks to an approximation argument. Given \(f \in S^2_{\text{loc}}(X_1 \times X_2)\) find a sequence \((f_n) \subset W^{1,2}(X_1 \times X_2)\) as in (2.2.2) and use the
locality of the differential to get that (3.2.11) holds even for \( f \in S^2_{\text{loc}}(X_1 \times X_2) \). Thus, since clearly \( df_{f_n} \to df \) in \( L^0(T^*(X_1 \times X_2)) \), from (3.2.11) we also get that \( |d(f_{f_n}) - df| \to 0 \) in \( L^0(X_2, L^0(X_1)) \); this proves both that \( df \in L^0(X_2, L^0(T^*X_1)) \) and that \( d(f_{f_n}) \to df \) in \( L^0(X_2, L^0(T^*X_1)) \).

Since this latter convergence does not depend on the particular choice of the sequence \((f_n) \subset S^2_{\text{loc}}(X_1 \times X_2) \) such that \( df_{f_n} \to df \) in \( L^0(T^*(X_1 \times X_2)) \), we proved also (3.2.10).

The last claim follows along the same approximation argument using the continuity property (3.2.10) (and the analogous one with \( X_1 \) and \( X_2 \) inverted).

Let \( \mathcal{M}_1, \mathcal{M}_2 \) be two \( L^0 \)-normed modules on a space \( X \). Then on the product \( \mathcal{M}_1 \times \mathcal{M}_2 \) we shall consider the structure of \( L^0 \)-normed module given by: the product topology, the multiplication by \( L^0 \)-functions given by \( f(v_1, v_2) := (f v_1, f v_2) \) and the pointwise norm defined as

\[ |(v_1, v_2)|^2 := |v_1|^2 + |v_2|^2. \]

It is readily verified that these actually endow \( \mathcal{M}_1 \times \mathcal{M}_2 \) with the structure of \( L^0 \)-normed module.

In particular, \( L^0(X_2, L^0(T^*X_1)) \times L^0(X_1, L^0(T^*X_2)) \) is a \( L^0(X_1 \times X_2) \)-normed module and we can define \( \Phi_1 \oplus \Phi_2 \) as

\[ \Phi_1 \oplus \Phi_2 : L^0(X_2, L^0(T^*X_1)) \times L^0(X_1, L^0(T^*X_2)) \to L^0(T^*(X_1 \times X_2)) \]

\[(\omega, \sigma) \mapsto \Phi_1(\omega) + \Phi_2(\sigma) \]

We then have the following result:

**Theorem 3.13** Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be two metric measure spaces such that Assumption 3.10 holds. Then \( \Phi_1 \oplus \Phi_2 \) is an isomorphism of modules, i.e. it is \( L^0(X_1 \times X_2) \)-linear, continuous, surjective and for every \( (\omega, \sigma) \in L^0(X_2, L^0(T^*X_1)) \) and \( \sigma \in L^0(X_1, L^0(T^*X_2)) \) satisfies

\[ |\Phi_1(\omega) + \Phi_2(\sigma)|^2 = |\omega|^2 + |\sigma|^2 \quad m_1 \times m_2 \text{-a.e..} \]  (3.2.13)

Moreover, for every \( f \in S^2_{\text{loc}}(X_1 \times X_2) \) it holds:

\[ df = \Phi_1(df_1) + \Phi_2(df_2). \]  (3.2.14)

**Proof** From Proposition 3.7 it is clear that \( \Phi_1 \oplus \Phi_2 \) is \( L^0(X_1 \times X_2) \)-linear and continuous. We now claim that

\[ |\Phi_1(df_1') + \Phi_2(df_2')|^2 = |df_1'|^2 \circ \pi_1 + |df_2'|^2 \circ \pi_2 \quad m_1 \times m_2 \text{-a.e.} \]  (3.2.15)

for any \( g \in S^2(X_1) \), \( h \in S^2(X_2) \), where \( \widehat{dg} \in L^0(X_2, L^0(T^*X_1)) \) is the function identically equal to \( dg \), and similarly for \( \widehat{dh} \in L^0(X_1, L^0(T^*X_2)) \). Fix such \( g, h \) and put \( f := g \circ \pi_1 + h \circ \pi_2 \in S^2_{\text{loc}}(X_1 \times X_2) \). Notice that trivially \( df_1 = dg \) and \( df_2 = dh \) for any \( x_1 \in X_1 \) and \( x_2 \in X_2 \), hence from the tensorization of Cheeger energy (recall the last claim of Lemma 3.12 above) we have

\[ |\Phi_1(df_1) + \Phi_2(df_2)|^2 = |dg| \circ \pi_1 + |dh| \circ \pi_2 \]

which is (3.2.15). Thus (3.2.13) holds for forms of the kind \( \widehat{dg}, \widehat{dh} \) and since these generate \( L^0(X_2, L^0(T^*X_1)) \) and \( L^0(X_1, L^0(T^*X_2)) \) respectively, by the locality and continuity of \( \Phi_1 \oplus \Phi_2 \) we conclude that (3.2.13) holds.
Now we prove (3.2.14). Let \( g \in L^\infty \cap W^{1,2}(X_1) \) and \( h \in L^\infty \cap W^{1,2}(X_2) \) be both with bounded support and consider \( f := g \circ \pi_1 h \circ \pi_2 \). Then \( f \in W^{1,2}(X_1 \times X_2) \) and the very definition of \( \Phi_1, \Phi_2 \) grant that
\[
d f = h \circ \pi_2 d(g \circ \pi_1) + g \circ \pi_1 d(h \circ \pi_2) = \Phi_1(h \, d g) + \Phi_2(g \, d h) = \Phi_1(d f_1) + \Phi_2(d f_2),
\]
so that in this case (3.2.14) is proved. By linearity, we get that (3.2.14) holds for general \( f \in \mathcal{A} \). Then using first the density of \( \mathcal{A} \) in \( W^{1,2}(X_1 \times X_2) \) and then property (2.2.2), taking into account the convergence property (3.2.10) we conclude that (3.2.14) holds for general \( f \in S^2_{\text{log}}(X_1 \times X_2) \), as claimed.

It remains to prove that \( \Phi_1 \oplus \Phi_2 \) is surjective. By (3.2.14) we know that its image contains the space of differential of functions in \( S^2_{\text{log}}(X_1 \times X_2) \), and thus \( L^0 \)-linear combinations of them. Since it preserves the pointwise norm, its image must be closed and since \( L^0(T^*(X_1 \times X_2)) \) is generated by differentials of functions in \( S^2_{\text{log}}(X_1 \times X_2) \), this is sufficient to conclude. \( \square \)

3.2.2 Other differential operators in product spaces

In the previous section we have seen how the differential behaves under products of spaces. We shall now investigate other differentiation operators under the assumption that \( X_1, X_2 \) are infinitesimally Hilbertian.

We start with the following simple orthogonality statement:

**Proposition 3.14** Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be infinitesimally Hilbertian spaces such that Assumption 3.10 holds. Then \(X_1 \times X_2\) is also infinitesimally Hilbertian and for every \( \omega_1 \in L^0(X_2, L^0(T^*X_1)) \) and \( \omega_2 \in L^0(X_1, L^0(T^*X_2)) \) we have
\[
\langle \Phi_1(\omega_1), \Phi_2(\omega_2) \rangle = 0 \quad m_1 \times m_2 \text{-a.e.} \tag{3.2.16}
\]

**Proof** The fact that \( W^{1,2}(X_1 \times X_2) \) is Hilbert is a direct consequence of the tensorization of the Cheeger energy and the assumption that both \( W^{1,2}(X_1) \) and \( W^{1,2}(X_2) \) are Hilbert. For (3.2.16) notice that
\[
|\omega_1|^2 + |\omega_2|^2 = |\Phi_1(\omega_1) + \Phi_2(\omega_2)|^2 = |\Phi_1(\omega_1)|^2 + |\Phi_2(\omega_2)|^2 + 2\langle \Phi_1(\omega_1), \Phi_2(\omega_2) \rangle,
\]
so that the conclusion follows recalling that \( \Phi_1, \Phi_2 \) preserve the pointwise norms. \( \square \)

By means of the musical isomorphisms (recall (2.2.3)) the map \( \Phi_1 \) induces a map, still denoted \( \Phi_1 \), from \( L^0(X_2, L^0(TX_1)) \) to \( L^0(T(X_1 \times X_2)) \) via:
\[
\Phi_1(X_\cdot) := \Phi_1(X^\cdot)^\sharp.
\]
Similarly for \( \Phi_2 \). It is clear that these newly defined \( \Phi_1, \Phi_2 \) have all the properties we previously proved for the same operators viewed as acting on forms. We also notice that for any \( \omega \in L^0(X_2, L^0(T^*X_1)) \) and \( X \in L^0(X_2, L^0(TX_1)) \) we have
\[
\Phi_1(\omega)(\Phi_1(X_\cdot))(x_1, x_2) = \omega(x_2)(X(x_1)) = m_1 \times m_2 \text{-a.e.} \ (x_1, x_2). \tag{3.2.17}
\]
Indeed, for \( \omega \equiv d g \) and \( X \equiv \nabla \tilde{g} \) for \( g, \tilde{g} \in S^2_{\text{loc}}(X_1) \) this is a direct consequence of the definition of \( \Phi_1 \) and the fact that \( \Phi_1 \) preserves the pointwise norm (and hence the pointwise scalar product), then the general case follows by \( L^0(X_1 \times X_2) \)-bilinearity and continuity of both sides.
Proposition 3.15 Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be infinitesimally Hilbertian spaces such that Assumption 3.10 holds. Then \(X \in D(\div_{\text{loc}}, X_1)\) if and only if \(\Phi_1(X) \in D(\div_{\text{loc}}, X_1 \times X_2)\), where \(\Phi \in L^0(X_2, L^0(TX_1))\) is the function identically equal to \(X\), and in this case

\[
\div(\Phi(X)) = \div(X) \circ \pi_1.
\]

Proof From the very definition of divergence it is readily verified that the thesis is equivalent to

\[
\int d f(\Phi(X)) \, d(m_1 \times m_2) = \int d f(X) \, d(m_1 \times m_2)
\]

for every \(f \in W^{1,2}(X_1 \times X_2)\) with bounded support.

For such \(f\) we have

\[
\int d f(\Phi(X)) \, d(m_1 \times m_2) \overset{\text{(3.2.14)}}{=} \int (\Phi_1(\div f) + \Phi_2(\div f'))(\Phi_1(X)) \, d(m_1 \times m_2)
\]

\[
\overset{\text{(3.2.16)}}{=} \int (\Phi_1(\div f))(\Phi_1(X)) \, d(m_1 \times m_2)
\]

\[
\overset{\text{(3.2.17)}}{=} \int d f(X) \, d(m_1 \times m_2),
\]

hence the conclusion. \(\square\)

A related property is the following:

Proposition 3.16 Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be infinitesimally Hilbertian spaces such that Assumption 3.10 holds. Let \(X = \Phi_1(X_1^1) + \Phi_2(X_2^2) \in L^2(TX_1 \times X_2)\) be such that:

- \(X_1^1 \in D(\div, X_1)\) for \(m_2\)-a.e. \(x_2 \in X_2\) with
  \[
  \int |\div(X_1^1)|^2 \, d(m_1 \times m_2) < \infty
  \]

- \(X_2^2 \in D(\div, X_2)\) for \(m_1\)-a.e. \(x_1 \in X_1\) with
  \[
  \int |\div(X_2^2)|^2 \, d(m_1 \times m_2) < \infty.
  \]

Then \(X \in D(\div)\) and

\[
\div(X)(x_1, x_2) = \div(X_1^1)(x_1) + \div(X_2^2)(x_2) \quad m_1 \times m_2\text{-a.e. } (x_1, x_2).
\]

Proof For any \(f \in W^{1,2}(X_1 \times X_2)\) with bounded support we have

\[
\int d f(X) \, d(m_1 \times m_2) \overset{\text{(3.2.14)}}{=} \int (\Phi_1(\div f) + \Phi_2(\div f'))(\Phi_1(X_1^1) + \Phi_2(X_2^2)) \, d(m_1 \times m_2)
\]

\[
\overset{\text{(3.2.16)}}{=} \int \Phi_1(\div f) \Phi_1(X_1^1) + \Phi_2(\div f') \Phi_2(X_2^2) \, d(m_1 \times m_2)
\]

\[
\overset{\text{(3.2.17)}}{=} \int \left( \int d f(X_1^1) \, d m_1 \right) \, d m_2 + \int \left( \int d f'(X_2^2) \, d m_2 \right) \, d m_1,
\]

which is the thesis. \(\square\)

These last two statements produce analogous ones for the Laplacian:

Corollary 3.17 Let \((X_1, d_1, m_1)\) and \((X_2, d_2, m_2)\) be infinitesimally Hilbertian spaces such that Assumption 3.10 holds. Then:

\(\square\) Springer
(i) $f \in D(\Delta_{\text{loc}}, X_1)$ if and only if $f \circ \pi_1 \in D(\Delta_{\text{loc}}, X_1 \times X_2)$ and in this case
\[ \Delta(f \circ \pi_1) = (\Delta f) \circ \pi_1. \]

(ii) Let $f \in W^{1,2}(X_1 \times X_2)$ be such that
- for $m_1$-a.e. $x_1 \in X_1$, $f^{x_1} \in D(\Delta, X_2)$ with $\int \|\Delta f^{x_1}\|_{L^2(X_2)}^2 \, dm_1 < \infty$,
- for $m_2$-a.e. $x_2 \in X_2$, $f_{x_2} \in D(\Delta, X_1)$ with $\int \|\Delta f_{x_2}\|_{L^2(X_1)}^2 \, dm_2 < \infty$.

Then $f \in D(\Delta, X_1 \times X_2)$ and
\[ \Delta f(x_1, x_2) = \Delta f_{x_2}(x_1) + \Delta f^{x_1}(x_2) = m_1 \times m_2$-a.e. $(x_1, x_2). \] (3.2.19)

Proof For the first claim simply notice that, directly from the definition, we have $f \in D(\Delta_{\text{loc}}, X_1)$ if and only if $\nabla f \in D(\text{div}_{\text{loc}}, X)$ and in this case $\text{div}(\nabla f) = \Delta f$. Similarly for $f \circ \pi_1$. Then observe that (3.2.1) grants that $\nabla(f \circ \pi_1) = \Phi_1(\nabla f)$ and apply Proposition 3.15 above to conclude.

The second claim follows by analogous considerations using Proposition 3.16 and the identity $\nabla f = \Phi_1(\nabla f) + \Phi_2(\nabla f)$ (recall (3.2.14)).

\[ \square \]

### 3.3 Flow of harmonic vector fields on $\text{RCD}(0, \infty)$ spaces

In this section we work on a fixed $\text{RCD}(0, \infty)$ space $(X, d, m)$ and study the Regular Lagrangian Flow of a fixed non-zero vector field $X \in L^2(TX)$ which is harmonic, i.e. $X^o \in D(\Delta_H)$ with $\Delta_H X^o = 0$. Recalling (2.2.10) we have that $\text{div}X = 0$, while (2.2.9) grants that $X$ is parallel, i.e. $X \in H^1_0(TX)$ with $\nabla X = 0$. This latter property also implies that $|X|$ is constant (see [17] for the details about this last claim).

We can thus apply Theorem 2.8 to deduce that there exists and is unique the Regular Lagrangian Flow ($\text{Fl}^X_t(X)$) of $X$. Aim of this section is to prove that:

- (i) the maps $\text{Fl}^X_t$ are measure preserving isometries
- (ii) if $Y$ is another harmonic vector field, then $\text{Fl}^X_t \circ \text{Fl}^Y_s = \text{Fl}^{X+sY}_t$ for any $t, s$.

Notice that by analogy with the smooth case, one would expect to need only the conditions $\text{div}X = 0$, $\nabla X = 0$ and that $X$ is a $\text{RCD}(K, \infty)$ space to get the above. Yet, it is unclear to us whether these are really sufficient, (part of) the problem being in the approximation procedure used in Proposition 3.20 which requires our stronger assumptions.

In what comes next we shall occasionally use the following simple fact: for $T, S$: $X \rightarrow X$ Borel we have
\[ T_{\#} \mu = S_{\#} \mu \quad \forall \mu \in \mathcal{P}(X) \text{ with bounded support and density } \Rightarrow T = S \quad \text{m.a.e..} \] (3.3.1)

Indeed, if $T \neq S$ on a set of positive measure, for some $r > 0$ we would have $d(T(x), S(x)) > 2r$ for a set of $x$’s of positive measure and thus using the separability of $X$ we would be able to find $\bar{x}$ such that $T_{\#} m(B_r(\bar{x})) > 0$. Thus $m(T^{-1}(B_r(\bar{x}))) > 0$ and letting $A \subset T^{-1}(B_r(\bar{x}))$ be any bounded Borel subset of positive $m$-measure, for $\mu := m(A)^{-1} m_1$, we would have that $T_{\#} \mu$ and $S_{\#} \mu$ are concentrated on disjoint sets, and thus in particular $T_{\#} \mu \neq S_{\#} \mu$.

With this said, we prove the following result, which shows that the flows of $X$ and $-X$ are one the inverse of the other:

**Lemma 3.18** Let $(X, d, m)$ be a $\text{RCD}(0, \infty)$ space and $X$ a harmonic vector field. Then for every $t \geq 0$ the following identities hold m.a.e.:
\[ \text{Fl}^{(X)}_t \circ \text{Fl}^{(X)}_t = \text{Id} \quad \text{and} \quad \text{Fl}^{(X)}_t \circ \text{Fl}^{(-X)}_t = \text{Id}. \]
Proposition 3.19 (Preservation of the measure) Let $\mu \in \mathcal{P}(X)$ be with bounded support and density, and consider the curves $[0, 1] \ni t \mapsto \mu_t, \mu_t \in \mathcal{P}(X)$ defined as

$$\mu_t := (\text{Fl}^{(X)}_1)_{t} \ast \mu$$

and

$$\tilde{\mu}_t := (\text{Fl}^{(-X)}_t)_{\ast} (\text{Fl}^{(X)}_1)_{\ast} \ast \mu,$$

notice that $\mu_0 = \tilde{\mu}_0$ and that they both solve the continuity equation (2.3.11) for $X_t = -X$ in the sense of Definition 2.9. By Theorem 2.10 we conclude that $\mu_1 = \tilde{\mu}_1$, i.e.

$$\mu = (\text{Fl}^{(-X)}_1 \circ \text{Fl}^{(X)}_1)_{\ast} \ast \mu.$$

The conclusion follows by the arbitrariness of $\mu$ and (3.3.1).

From this proposition and the semigroup property (2.3.10) of Regular Lagrangian Flows, it follows that defining $\text{Fl}^{(X)}_{t} := \text{Fl}^{(-X)}_{t} \ast \mu$ for $t \geq 0$ we have

$$\text{Fl}^{(X)}_t \circ \text{Fl}^{(X)}_s = \text{Fl}^{(X)}_{t+s} \text{ m-a.e. } \forall t, s \in \mathbb{R}. \tag{3.3.2}$$

Proposition 3.19 (Preservation of the measure) Let $(X, d, m)$ be a RCD$(0, \infty)$ space and $X$ a harmonic vector field. Then for every $t \in \mathbb{R}$ we have

$$\left(\text{Fl}^{(X)}_t\right)_{\ast} m = m. \tag{3.3.3}$$

Proof Simply notice that from $\text{div}(X) = \text{div}(-X) = 0$ and (2.3.9), for any $t \geq 0$ we have

$$m = \left(\text{Fl}^{(X)}_t \circ \text{Fl}^{(-X)}_t\right)_{\ast} m = \left(\text{Fl}^{(X)}_t\right)_{\ast} \left(\text{Fl}^{(-X)}_t\right)_{\ast} m \leq \left(\text{Fl}^{(X)}_t\right)_{\ast} m \leq m$$

forcing the inequalities to be equalities.

Recall that the heat flow $(h_t)$ on $X$ is firstly defined as the $L^2$-gradient flow of the Cheeger energy and then extended to a flow on $L^1 + L^\infty$ by monotonicity and continuity. On the other hand, the ‘Hodge’ heat flow $(h_{H,t})$ is defined on $L^2(T^*X)$ as the gradient flow of the functional

$$L^2(T^*X) \ni \omega \mapsto \frac{1}{2} \int |d\omega|^2 + |\delta \omega|^2 \, dm \text{ if } \omega \in H^{1,2}_H(T^*X),$$

For us it will be relevant to know the relation

$$h_{H,t} df = dh_t f \quad \forall f \in W^{1,2}(X) \tag{3.3.4}$$

and the improved Bakry–Émery estimate:

$$|h_{H,t} \omega|^2 \leq e^{-2K} |h_t (|\omega|^2)|, \text{ m-a.e. } \forall t \geq 0, \omega \in L^2(T^*X), \tag{3.3.5}$$

valid on RCD$(K, \infty)$ spaces. See [17] for further details about these.

With this said, we can now prove the following lemma, which is key to show that $\text{Fl}^{(X)}_t$ is an isometry.

Proposition 3.20 (Euler’s equation for $X$) Let $(X, d, m)$ be a RCD$(0, \infty)$ space and $X$ a harmonic vector field. Then for any $f \in W^{1,2}(X)$ it holds

$$h_t ( \langle \nabla f, X \rangle ) = \langle \nabla h_t f, X \rangle, \text{ m-a.e., } \forall t \geq 0. \tag{3.3.6}$$

Moreover, for every $f \in D(\Delta)$ with $\Delta f \in W^{1,2}(X)$, we have $\langle \nabla f, X \rangle \in D(\Delta)$ and

$$\Delta \langle \nabla f, X \rangle = \langle \nabla \Delta f, X \rangle, \text{ m-a.e.. } \tag{3.3.7}$$
Proof We apply (3.3.5) in our space to the form $X^b + \varepsilon \, df$ to obtain

$$|h_{H,t}(X^b + \varepsilon \, df)|^2 \leq h_t(|X + \varepsilon \nabla f|^2).$$  \hspace{1cm} (3.3.8)

We have already observed that the fact that $X^b$ is harmonic grants that $|X|$ is constant, say $|X| \equiv c$. The harmonicity also grants that $h_{H,t}(X^b) = X^b$ for every $t \geq 0$, hence we have

$$|h_{H,t}(X^b)|^2 \equiv c^2 \equiv h_t(|X|^2)$$

for any $t \geq 0$. Therefore,

$$c^2 + 2\varepsilon \langle X, h_{H,t}(df) \rangle + \varepsilon^2 |h_{H,t}(df)|^2 \leq c^2 + 2\varepsilon h_t(X, \nabla f) + \varepsilon^2 h_t(|df|^2)$$

and the arbitrariness of $\varepsilon \in \mathbb{R}$ implies

$$\langle X, h_{H,t} df \rangle = 2h_t(X, \nabla f),$$

which by (3.3.4) is (3.3.6). Then (3.3.7) comes by differentiating (3.3.6) at $t = 0$. \hspace{1cm} \Box

**Proposition 3.21** (Preservation of the Dirichlet energy) Let $(X, d, m)$ be a RCD($0, \infty$) space and $X$ a harmonic vector field. Then for every $t \in \mathbb{R}$ we have

$$E\left(f \circ Fl^X_t\right) = E(f) \quad \forall f \in W^{1,2}(X).$$ \hspace{1cm} (3.3.9)

Proof Fix $f \in W^{1,2}(X)$, put $f_t := f \circ Fl^X_t$ and notice that since $E(h_\varepsilon \, g) \rightarrow E(g)$ as $\varepsilon \downarrow 0$ for any $g \in L^2(X)$, it is sufficient to prove that for any $\varepsilon > 0$ we have

$$E(h_\varepsilon \, f_t) = E(h_\varepsilon \, f) \quad \forall t \in \mathbb{R}.$$ 

Thus fix $\varepsilon > 0$ and notice that Proposition 2.7 grants that $t \mapsto f_t \in L^2(X)$ is Lipschitz. This in conjunction with the fact that $h_\varepsilon : L^2(X) \rightarrow W^{1,2}(X)$ is Lipschitz ensures that $t \mapsto h_\varepsilon \, f_t \in W^{1,2}(X)$ is Lipschitz.

We now compute the derivative of the Lipschitz map $t \mapsto E(h_\varepsilon \, f_t)$ and start noticing that

$$\int |\nabla h_\varepsilon f_{t+h} - \nabla h_\varepsilon f_t|^2 \, dm = \int |\nabla h_\varepsilon (f_{t+h} - f_t)|^2 + 2|\nabla h_\varepsilon f_t, \nabla h_\varepsilon (f_{t+h} - f_t)| \, dm,$$

so that the Lipschitz regularity of $t \mapsto h_\varepsilon \, f_t \in W^{1,2}(X)$ grants that for any $t \in \mathbb{R}$ it holds

$$\lim_{h \rightarrow 0} \int \frac{|\nabla h_\varepsilon f_{t+h} - \nabla h_\varepsilon f_t|^2}{2h} \, dm = \lim_{h \rightarrow 0} \int \langle \nabla h_\varepsilon f_t, \nabla h_\varepsilon f_{t+h} - h_\varepsilon f_t \rangle \, dm.$$ 

Hence

$$\frac{d}{dt} E(h_\varepsilon f_t) = - \lim_{h \rightarrow 0} \int \Delta h_\varepsilon f_t \, \frac{h_\varepsilon f_{t+h} - h_\varepsilon f_t}{h} \, dm = - \lim_{h \rightarrow 0} \int \Delta h_\varepsilon f_t \, \frac{f_t \circ Fl^X_{t+h} - f_t}{h} \, dm$$

by (3.3.3)

$$= - \lim_{h \rightarrow 0} \int \frac{(\Delta h_\varepsilon f_t) \circ Fl^X_{t+h} - \Delta h_\varepsilon (f_t)}{h} \, f_t \, dm,$$

by the last claim in Proposition 2.7

$$= - \int \langle \nabla \Delta h_\varepsilon f_t, X \rangle \, f_t \, dm.$$ 

To conclude it is therefore sufficient to prove that for any $g \in L^2(X)$ it holds

$$\int \langle \nabla \Delta h_\varepsilon g, X \rangle \, g \, dm = 0 \hspace{1cm} (3.3.10)$$
Hence fix \( g \in L^2(X) \) and notice that
\[
\int (\nabla \Delta_h g, X) \, g \, d\mu (3.3.6) = \int h_e (\nabla \Delta_h g, X) \, g \, d\mu (3.3.11)
\]
and, recalling that \( \text{div} X = 0 \), that
\[
\int (\nabla \Delta_h g, X) \, h_e g \, d\mu (3.3.7) = \int h_e g (X, \nabla \Delta_h g) \, d\mu.
\]
This proves (3.3.10) and the theorem. \( \square \)

We therefore can conclude that:

**Theorem 3.22** Let \( (X, d, m) \) be a RCD\((0, \infty)\) space and \( X \) a harmonic vector field. Then for every \( t \in \mathbb{R} \) the map \( \text{Fl}_t^X \) has a continuous representative and this representative is a measure preserving isometry.

**Proof** Use the preservation of measure proved in Proposition 3.19 and the one of Dirichlet energy proved in Proposition 3.21 in conjunction with Theorem 2.5. \( \square \)

From now on we shall identify \( \text{Fl}_t^X \) with its continuous representative. It is readily verified from the construction that the group property 3.3.2 holds everywhere.

One of the consequences of the fact that \( \text{Fl}_t^X \) is an automorphism of \( (X, d, m) \) is that
\[
f \in \text{Test}(X) \Rightarrow f \circ \text{Fl}_t^X \in \text{Test}(X). \tag{3.3.12}
\]
This can be seen by noticing that since \( \text{Fl}_t^X \) is a measure preserving isometry, directly from the definition of Sobolev space we have
\[
f \in W^{1,2}(X) \iff f \circ \text{Fl}_t^X \in W^{1,2}(X) \quad \text{and in this case } |\text{d}f| \circ \text{Fl}_t^X = |\text{d}(f \circ \text{Fl}_t^X)|.
\]
From this fact and the definition of Laplacian we then deduce that
\[
f \in D(\Delta) \iff f \circ \text{Fl}_t^X \in D(\Delta) \quad \text{and in this case } (\Delta f) \circ \text{Fl}_t^X = \Delta(f \circ \text{Fl}_t^X).
\]
A suitable iteration of these arguments then yields (3.3.12).

Recall also (see [17]) that being \( \text{Fl}_t^X \) invertible and of bounded deformation, its differential \( \text{dFl}_t^X \) is a map from \( L^2(TX) \) into itself (well) defined by:
\[
\text{d}f \left( \text{dFl}_t^X (Y) \right) = \text{d} \left( f \circ \text{Fl}_t^X \right)(Y) \circ \text{Fl}_t^X \quad \forall f \in W^{1,2}(X). \tag{3.3.13}
\]

We now want to prove that if \( X, Y \) are both harmonic, their flows commute. The proof is based on the following lemma:

**Lemma 3.23** Let \( (X, d, m) \) be a RCD\((0, \infty)\) space and \( X, Y \) harmonic vector fields. Then
\[
\text{dFl}_s^X (Y) = Y \quad \forall s \in \mathbb{R}.
\]

**Proof** Since differential of test functions generate the whole cotangent module, the claim will follow if we show that for any \( f \in \text{Test}(X) \) the map \( \mathbb{R} \ni s \mapsto \text{d}f(\text{dFl}_s^X (Y)) \) is constant.

Now observe that a map \( t \mapsto v_t \in B, \) with \( B \) Banach space, is constant if and only if for any \( t \) it holds \( \frac{v_{t+h} - v_t}{h} \to 0 \) in the strong topology as \( h \to 0 \). To see this apply the analogous property for real valued functions to \( t \mapsto \ell(v_t) \) for \( \ell \in B' \) arbitrary.
Hence taking account of the equality in (3.3.13) and recalling (3.3.12), in order to conclude it is sufficient to prove that for any \( f \in \text{Test}(X) \)
\[
\frac{d \left( f \circ \text{Fl}_h^{(X)} \right)(Y) \circ \text{Fl}_{1-h}^{(X)} - d f(Y)}{h} \quad \text{goes to 0 in the strong } L^2(X) - \text{ topology as } h \to 0.
\]

To this aim, start observing that
\[
\frac{d \left( f \circ \text{Fl}_h^{(X)} \right)(Y) \circ \text{Fl}_{1-h}^{(X)} - d f(Y)}{h} = \frac{d \left( f \circ \text{Fl}_h^{(X)} - f \right)}{h}(Y) \circ \text{Fl}_{1-h}^{(X)} + \frac{d f(Y) \circ \text{Fl}_{1-h}^{(X)} - d f(Y)}{h}.
\]

Since \( f \in \text{Test}(X) \) and \( Y \in H^{1,2}_{C}(TX) \) we have \( d f(Y) \in W^{1,2}(X) \) (see [17] for details about this implication) and thus from the last claim in Proposition 2.7 we have
\[
\lim_{s \to 0} \frac{d f(Y) \circ \text{Fl}_{s}^{(X)} - d f(Y)}{s} = -d(d f(Y))(X) \quad \text{in } L^2(X),
\]
hence to conclude it is sufficient to show that
\[
\lim_{s \to 0} \frac{d \left( f \circ \text{Fl}_s^{(X)} - f \right)}{s}(Y) \circ \text{Fl}_{1-s}^{(X)} = d(d f(Y))(Y). \tag{3.3.14}
\]

Let us start proving that
\[
\frac{f \circ \text{Fl}_s^{(X)} - f}{s} \to d f(X) \quad \text{as } s \to 0 \quad \text{in } W^{1,2}(X). \tag{3.3.15}
\]

Notice that (2.3.5) grants convergence in \( L^2(X) \); moreover the bound
\[
\left| d \left( \frac{f \circ \text{Fl}_s^{(X)} - f}{s} \right) \right|^2 = \left| \frac{1}{s} \int_0^s d(d f(X) \circ \text{Fl}_r^{(X)}) \ dr \right|^2 \\
\leq \frac{1}{s} \int_0^s \left| d(d f(X) \circ \text{Fl}_r^{(X)}) \right|^2 \ dr = \frac{1}{s} \int_0^s \left| d(f(X)) \right|^2 \circ \text{Fl}_r^{(X)} \ dr
\]
and the fact that \( (\text{Fl}_r^{X})_* m = m \) grant that \( \lim_{s \to 0} \| \frac{f \circ \text{Fl}_s^{(X)} - f}{s} \|_{W^{1,2}} \leq \| d f(X) \|_{W^{1,2}} \) which is sufficient to get (3.3.15).

From (3.3.15) we deduce that
\[
\frac{d \left( f \circ \text{Fl}_s^{(X)} - f \right)}{s}(Y) \to d(d f(X))(Y) \quad \text{as } s \to 0 \quad \text{in } L^2(X)
\]
hence (3.3.14) follows from (2.3.5).

\[\square\]

**Theorem 3.24** Let \((X, d, m)\) be a \(\text{RCD}(0, \infty)\) space and \(X, Y \in L^2(TX)\) be two harmonic vector fields. Then for any \(t, s \in \mathbb{R}\) it holds
\[
\text{Fl}_t^{X} \circ \text{Fl}_s^{Y} = \text{Fl}_{t+s}^{X+y}.
\]
Proof For any \( r \in \mathbb{R} \) consider the map \( G_r := \text{Fl}_r^X \circ \text{Fl}_r^Y \). Now take \( f \in W^{1,2}(X) \) and observe that \( f \circ \text{Fl}_r^X \in W^{1,2}(X) \), as a consequence of Theorem 3.22, and that from Proposition 2.7 it easily follows that \( r \mapsto f \circ G_r \in L^2(X) \) is Lipschitz. By direct computation we have:
\[
\frac{d}{dr} (f \circ G_r) = \frac{d}{dr} \left( f \circ \text{Fl}_r^X \circ \text{Fl}_r^Y \right) = s \ d (f \circ \text{Fl}_r^X) (Y) \circ \text{Fl}_r^Y + t \ d f (X) \circ \text{Fl}_r^X \circ \text{Fl}_r^Y.
\] (3.3.16)
Using first identity (3.3.13) and then Lemma 3.23 we have
\[
d \left( f \circ \text{Fl}_r^X \right) (Y) \circ \text{Fl}_r^Y = d f \left( d \text{Fl}_r^X (Y) \right) \circ \text{Fl}_r^X \circ \text{Fl}_r^Y = d f (Y) \circ \text{Fl}_r^X \circ \text{Fl}_r^Y
\]
and thus from (3.3.16) we obtain
\[
\frac{d}{dr} (f \circ G_r) = s \ d f (Y) \circ \text{Fl}_r^X \circ \text{Fl}_r^Y + t \ d f (X) \circ \text{Fl}_r^X \circ \text{Fl}_r^Y = d f (tX + sY) \circ G_r
\]
and since it is obvious by construction that \( (G_r) \) has the properties (i), (ii) in Definition 2.6, by Proposition 2.7 we deduce that \( (G_r) \) is a Regular Lagrangian Flow of \( tX + sY \) and thus by the uniqueness part of Theorem 2.8 we deduce that for any \( r \geq 0 \) we have
\[\text{Fl}_r^X \circ \text{Fl}_r^Y = \text{Fl}_r^{tX+sY}\]
m-a.e.. In particular this holds for \( r = 1 \) and since both sides are continuous functions, equality holds everywhere. \( \square \)

4 Proof of the main result

4.1 Setting

Here we fix the assumptions and notations that will be used in the rest of the text.

\((X, d, m)\) is a \(\text{RCD}^n(0, N)\) metric measure space with \(\text{supp}(m) = X\), \(N \in \mathbb{N}, N > 0\), and such that \(\dim(H^1_{dR})(X) = N\).

The theory developed in [17] grants the existence of \(N\) harmonic vector fields \(X_1, \ldots, X_N\) which are orthogonal in \(L^2(TX)\). As in Sect. 3.3, since the Ricci curvature is non-negative, these vector fields belong to \(H^1_{dR}(TX)\) and are parallel, i.e. \(\nabla X_i = 0\) for every \(i\). It follows that \((X_i, X_j) \in W^{1,2}(X)\) with
\[
d \langle X_i, X_j \rangle = \nabla X_i (\cdot, X_j) + \nabla X_j (\cdot, X_i) = 0 \quad \text{m-a.e.},
\]
which in turn grants that \((X_i, X_j)\) is m-a.e. equal to a constant function. Since \(\int \langle X_i, X_j \rangle \, dm = 0\) for \(i \neq j\) we conclude that the \(X_i\)'s are pointwise orthogonal. The same argument also shows that up to normalization we can, and will, assume that \(|X_i| = 1\) m-a.e. for every \(i\). In particular, since these vector fields are in \(L^2(TX)\), we have
\[
m(X) < \infty. \tag{4.1.1}
\]

We shall work with the product space \(X \times \mathbb{R}^N\) which will be equipped with the measure \(m \times L^N\) and the distance
\[
(d \otimes d_{\text{Eucl}})^2((x, a), (y, b)) := d^2(x, y) + |a - b|^2.
\]
We shall also define vector fields \(Y_i \in L^0(X \times \mathbb{R}^N), i = 1, \ldots, N\) as
\[
Y_i := \Phi_2(\nabla \pi_i) \quad \forall i = 1, \ldots, N,
\]
where \( \pi_i : \mathbb{R}^N \rightarrow \mathbb{R} \) is the projection on the \( i \)th coordinate, \( \nabla \pi_i \in L^0(X, L^0(T\mathbb{R}^N)) \) is the function identically equal to \( \nabla \pi^i \in L^0(T\mathbb{R}^N) \) and where \( \Phi_2 : L^0(X, L^0(T\mathbb{R}^N)) \rightarrow L^0(T(X \times \mathbb{R}^N)) \) is defined in Proposition 3.7.

We also define the map \( T : X \times \mathbb{R}^N \rightarrow X \) by
\[
T : X \times \mathbb{R}^N \rightarrow X
(\cdot, a = (a_1, \ldots, a_N)) \mapsto Fl_{a_1}^{(X_1)} \circ \cdots \circ Fl_{a_N}^{(X_N)}(\cdot).
\] (4.1.2)

### 4.2 Preliminary considerations

Let us collect some easy consequences of our assumptions that can be derived from the discussion made in the previous sections. Start recalling from [5] (see also [4]) that the product of two \( \text{RCD}(0, \infty) \) spaces is also \( \text{RCD}(0, \infty) \), so that \( X \times \mathbb{R}^N \) is \( \text{RCD}(0, \infty) \).

From the fact that the \( \nabla \pi_i \) are a pointwise orthonormal base for \( L^0(T\mathbb{R}^N) \) and the fact that \( \Phi_2 \) preserves the pointwise norm we deduce that
\[
(Y_i, Y_j) = \delta_{ij} \ m \times \mathcal{L}^N - a.e. \ \forall i, j
\]
and from the very definition of \( \Phi_2 \) we have that
\[
Y_i = \nabla(\pi_i \circ \pi|^{\mathbb{R}^N}).
\] (4.2.1)

Since \( \pi_i : \mathbb{R}^N \rightarrow \mathbb{R} \) is harmonic, we have \( \nabla \pi_i \in D(\text{div}_{\text{loc}}, \mathbb{R}^N) \) with \( \text{div}(\nabla \pi_i) = 0 \) and thus from Propositions 3.15 and 3.11 we deduce that \( Y_i \in D(\text{div}_{\text{loc}}, X \times \mathbb{R}^N) \) with
\[
\text{div}Y_i \equiv 0.
\] (4.2.2)

Taking into account (2.2.7) we also obtain that \( Y_i^b \in D(\Delta H_{\text{loc}}, \mathbb{R}^N) \) with \( \Delta H Y_i^b = 0 \) and since \( |\nabla \pi_i| \equiv 1 \) and \( \Phi_2 \) preserves the pointwise norm we also deduce that \( |Y_i| \equiv 1 \): these facts together with (2.2.8) grant that \( Y_i \in W^{1,2}_{C,\text{loc}}(TX) \) with
\[
\nabla Y_i \equiv 0.
\] (4.2.3)

Concerning the map \( T \), from Theorem 3.24 we deduce that
\[
T(T(x, a), b) = T(x, a + b) \quad \forall x \in X, \ a, b \in \mathbb{R}^N,
\] (4.2.4)
so that we shall occasionally think at \( T \) as an action of \( \mathbb{R}^N \) on \( X \). Theorem 3.22 grants that this action is made of isometries, i.e.
\[
T(\cdot, a) : X \rightarrow X \quad \text{is an isometry for any} \ a \in \mathbb{R}^N.
\] (4.2.5)

From Theorem 3.24 we also have
\[
T(x, a) = Fl_{a_1}^{(X_1)}(x) \quad \text{for} \ x_a := \sum_{i=1}^{N} a_i X_i
\]
and since the pointwise orthonormality of the \( X_i \)'s gives \( |X_a|^2 = \sum_{i=1}^{N} a_i X_i |^2 = \sum_i |a_i|^2 = |a|^2 \) m-a.e., from (3.3.3) we deduce that for m-a.e. \( x \) it holds
\[
d(x, T(x, a)) \leq \int_{0}^{1} |X_a| \circ Fl_{x}^{(X_a)} \, dt \leq \|X_a\|_{L^\infty} = |a|.
\]
Let us put for every $A \subset \mathbb{R}^N$ Borel. This identity, (4.2.5) and (4.2.6) grant in particular that $T : X \times \mathbb{R}^N \to X$ is of local bounded deformation.

### 4.3 An explicit formula for regular Lagrangian flows on $X$

Aim of this section is to provide, in Proposition 4.4, an explicit representation formula for Regular Lagrangian Flows on $X$ in terms of the map $T$. The starting point is the following:

**Proposition 4.1** (Conjugation property) *With the same notations and assumptions as in Sect. 4.1 the following holds. For any $i = 1, \ldots, N$, $t \in \mathbb{R}$ and $f \in W^{1,2}_{\text{loc}}(X)$ it holds*

$$
\text{d}(f \circ T)(Y_i) = \text{d} f(X_i) \circ T \quad \text{m} \times \mathcal{L}^N - \text{a.e.} 
$$

**Proof** Let us put $\tilde{F}_t^i(x, a) := (x, a + te_i)$ and notice that by the very definition of $T$ and identity (4.2.4) we have

$$
\tilde{F}_t^i \circ T = T \circ \tilde{F}_t^i. 
$$

Fix $f \in W^{1,2}_{\text{loc}}(X)$ and recall Proposition 2.7 to get

$$
\text{d} f(X_i) \circ T = \left( \lim_{t \downarrow 0} \frac{f \circ \tilde{F}_t^i(X_i) - f}{t} \right) \circ T = \lim_{t \downarrow 0} \frac{f \circ T \circ \tilde{F}_t^i - f \circ T}{t},
$$

the first limit being in $L^1_{\text{loc}}(X)$ and the second in $L^2_{\text{loc}}(X \times \mathbb{R}^N)$. Hence to conclude it is sufficient to show that for any $\tilde{f} \in W^{1,2}_{\text{loc}}(X \times \mathbb{R}^N)$ and $\rho \in L^\infty(X \times \mathbb{R}^N)$ with bounded support we have

$$
\lim_{t \downarrow 0} \int \tilde{f} \circ \tilde{F}_t^i - \tilde{f} \rho \, \text{d}(\text{m} \times \mathcal{L}^N) = \int \tilde{f} \circ \tilde{F}_t^i \rho \, \text{d}(\text{m} \times \mathcal{L}^N). 
$$

By the linearity in $\rho$ of this expression we can further assume that $\rho$ is a probability density. Then put $\mu := \rho \text{m}$ and $\pi := (\tilde{F}_t^i)_* \mu$, where here $\tilde{F}_t^i : X \times \mathbb{R}^N \to C([0, 1], X \times \mathbb{R}^N)$ is the map sending $(x, a)$ to the curve $[0, 1] \ni t \mapsto \tilde{F}_t^i(x, a)$. Notice that $\pi$ is a test plan on $X \times \mathbb{R}^N$ which is concentrated on curves with speed constantly equal to 1, thus for any $\tilde{f} \in W^{1,2}_{\text{loc}}(X \times \mathbb{R}^N)$ we have

$$
\int \frac{\tilde{f} \circ \tilde{F}_t^i}_* \mu - \tilde{f} \circ \tilde{F}_t^i \, d\mu = \int t \tilde{f}(\gamma_t) - \tilde{f}(\gamma_0) \, d\pi(\gamma)
$$

$$
\leq \frac{1}{t} \int_0^t |\tilde{f}(\gamma_s)| |\dot{\gamma}_s| \, ds \, d\pi(\gamma)
$$

$$
\leq \frac{1}{2t} \int_0^t |\tilde{f}(\gamma_s)|^2 \, ds \, d\pi(\gamma) + \frac{1}{2t} \int_0^t |\dot{\gamma}_s|^2 \, ds \, d\pi(\gamma)
$$

$$
= \frac{1}{2t} \int_0^t \int_0^1 |\tilde{f}|^2 \circ \tilde{F}_t^i \, d\mu \, ds + \frac{1}{2}.
$$
Recognizing the flat torus among \( \text{RCD}^*(0,N) \) spaces via the ...

Recalling (2.3.5) we thus have

\[
\lim_{t \downarrow 0} \int \tilde{f} d(\tilde{F}_t) \ast \mu - \int \tilde{f} d\mu \leq \frac{1}{2} \int |d\tilde{f}|^2 d\mu + \frac{1}{2}.
\]

(4.3.4)

Now put for brevity \( f_i := \pi^i \circ \pi^{RN} \), so that \( f_i \) is 1-Lipschitz, (4.2.1) reads as

\[
\nabla f_i = Y_i
\]

(4.3.5)

and by construction it holds \( f_i \circ \bar{F}_t = f_i + s \), so that

\[
\lim_{t \downarrow 0} \int f_i d(\bar{F}_t) \ast \mu - \int f_i d\mu \leq \frac{1}{2} \int |d(\tilde{f})|^2 d\mu + \frac{1}{2}.
\]

(4.3.6)

(In the terminology of [19] we just proved that \( \pi \) represents the gradient of \( f_i \) and we are now going to use the link between ‘horizontal and vertical’ derivatives). Writing (4.3.4) for \( f_i + \varepsilon \tilde{f} \) in place of \( \tilde{f} \) and subtracting (4.3.6) we obtain

\[
\lim_{t \downarrow 0} \varepsilon \int f_i d(\bar{F}_t) \ast \mu - \int f_i d\mu \leq \frac{1}{2} \int |d(f + \varepsilon \tilde{f})|^2 - |df|^2 d\mu \quad (4.3.5)
\]

\[
\frac{\varepsilon^2}{2} |d\tilde{f}|^2 d\mu.
\]

Dividing by \( \varepsilon > 0 \) (resp. \( \varepsilon < 0 \)) and letting \( \varepsilon \downarrow 0 \) (resp. \( \varepsilon \uparrow 0 \)) we obtain (4.3.3) and the conclusion.

We now introduce a map \( \Psi : L^0(TX) \to L^0(T(X \times \mathbb{R}^N)) \) as

\[
\Psi(v) := \sum_{i=1}^N \langle v, X_i \rangle \circ T \ Y_i
\]

(4.3.7)

Notice that as a direct consequence of (4.3.1) and the identity \( v = \sum_{i=1}^N \langle v, X_i \rangle X_i \) we have that

\[
d(f \circ T)(\Psi(v)) = df(v) \circ T \ m \times \mathcal{L}^N \quad \text{a.e.} \quad \forall f \in W^{1,2}_{loc}(X).
\]

(4.3.8)

Many of the properties of the map \( \Psi \) will be based on this identity (which, we remark, also depends on the fact that the vector fields \( X_1, \ldots, X_N \) form a basis of \( L^2(TX) \) and thus on our ‘maximality’ assumption \( \dim(H^{1,2}_{dR})(X) = N) \). We start with the following simple lemma:

**Lemma 4.2** With the same notations and assumptions as in Sect. 4.1 and with \( \Psi \) defined as in (4.3.7), the following holds. Let \( v \in L^\infty \cap W^{1,2}_{C,loc}(TX) \). Then:

(i) \( \langle v, X_i \rangle \in W^{1,2}(X) \) for every \( i \) and \( v \in D(\text{div}) \) with

\[
\text{div}(v) = \sum_{i=1}^N \text{div}((\langle v, X_i \rangle)(X_i))
\]

(4.3.9)

(ii) \( \Psi(v) \in L^\infty \cap W^{1,2}_{C,loc} \cap D(\text{div}_{loc})(T(X \times \mathbb{R}^n)) \) with

\[
\nabla(\Psi(v)) = \sum_{i=1}^N \nabla((\langle v, X_i \rangle \circ T) \otimes Y_i),
\]

\[
\text{div}(\Psi(v)) = \text{div}(v) \circ T.
\]
Proof (i) From [17] we know that the assumptions on \( v \) grant that \( \langle v, X \rangle \in W^{1,2}_{\text{loc}}(X) \) for every \( X \in L^\infty \cap H_C^{1,2}(TX) \) with

\[
d(v, X) = \nabla v(\cdot, X) + \nabla X(\cdot, v).
\]

Picking \( X := X_i \) and recalling that \( D(\Delta_H) \subseteq (H_C^{1,2}(TX))^b \) by the very definition of \( \Delta_H \), we conclude that \( \langle v, X_i \rangle \) belongs to \( W^{1,2}(X) \), as claimed. Now put \( a_i := \langle v, X_i \rangle \) for brevity, so that \( v = \sum_i a_i X_i \), let \( f \in W^{1,2}(X) \) and notice that

\[
\int d(f(v)) \, dm = \sum_{i=1}^N \int d(f(a_i X_i)) \, dm = - \sum_{i=1}^N \int f \, \text{div}(a_i X_i) \, dm = - \int \sum_{i=1}^N f \, da_i(X_i) \, dm,
\]

having used the fact that \( \text{div}(X_i) = 0 \). This proves both \( v \in D(\text{div}) \) and (4.3.9).

(ii) The assumption \( v \in L^\infty(TX) \) trivially yields \( a_i \in L^\infty(X) \) and since \( Y_i \in L^\infty \cap H_C^{1,2}(X \times \mathbb{R}^N) \) with \( \nabla Y_i = 0 \) (recall (4.2.3)), we have \( (a_i \circ T) Y_i \in W^{1,2}_{\text{c,loc}}(T(X \times \mathbb{R}^N)) \) with

\[
\nabla((a_i \circ T) Y_i) = \nabla(a_i \circ T) \otimes Y_i + a_i \circ T \nabla Y_i = (a_i \circ T) \otimes Y_i.
\]

The fact that \( \Phi(v) \in L^\infty \cap W^{1,2}_{\text{c,loc}}(T(X \times \mathbb{R}^N)) \) and the formula for \( \nabla(\Phi(v)) \) follow.

We turn to the divergence: for \( g \in W^{1,2}(X \times \mathbb{R}^N) \) with bounded support we have

\[
\int dg(\Phi(v)) \, d(m \times \mathcal{L}^N) = \sum_{i=1}^N \int dg(a_i \circ T Y_i) \, d(m \times \mathcal{L}^N)
\]

because \( \text{div}(Y_i) = 0 \)

\[
= - \sum_{i=1}^N \int g \, d(a_i \circ T)(Y_i) \, d(m \times \mathcal{L}^N)
\]

by (4.3.1)

\[
= - \sum_{i=1}^N \int g \, da_i(X_i) \circ T \, d(m \times \mathcal{L}^N),
\]

which by (4.3.9) is the conclusion.

Let \( (v_t) \in L^\infty([0, 1], L^2(TX)) \cap L^2([0, 1], W^{1,2}_C(TX)) \) be such that \( \text{div}(v_t) \in L^\infty([0, 1], L^\infty(X)) \), so that in particular the Regular Lagrangian Flow \( \text{Fl}^{(v_t)}_s \) is well defined. The integrability condition of \( (v_t) \) ensures that \( (\langle v_t, X_i \rangle) \in L^\infty([0, 1], L^2(X)) \) for every \( i = 1, \ldots, N \) and thus from (2.3.1) we see that \( (\langle v_s, X_i \rangle \circ \text{Fl}^{(v_t)}_s) \in L^\infty([0, 1], L^2(X)) \) as well. Hence the functions

\[
A_{i, t} := \int_0^t \langle v_s, X_i \rangle \circ \text{Fl}^{(v_t)}_s \, ds \in L^2(X), \quad t \in [0, 1], \quad i = 1, \ldots, N,
\]

are well defined. We then have the following result:

**Lemma 4.3** With the same assumptions and notation as in Sect. 4.1, let \( (v_t) \in L^\infty([0, 1], L^2(TX)) \cap L^2([0, 1], W^{1,2}_C(TX)) \) be such that \( \text{div}(v_t) \in L^\infty([0, 1], L^\infty(X)) \) and define \( \Psi \) as in (4.3.7).

Then the vector fields \( \Psi(v_t) \) satisfy the assumptions of Theorem 2.8 and for any \( s \in \mathbb{R} \) the following identities hold \( m \times \mathcal{L}^N \)-a.e.:

\[
T \circ \text{Fl}^{(\Psi(v_t))}_s = \text{Fl}^{(v_t)}_s \circ T,
\]

\[
\pi^X \circ \text{Fl}^{(\Psi(v_t))}_s = \pi^X
\]

\[
\pi_i \circ \pi^\mathbb{R}^N \circ \text{Fl}^{(\Psi(v_t))}_s = \pi_i \circ \pi^\mathbb{R}^N + A_{i, s} \circ T.
\]
**Proof** The fact that the $\Psi(v_s)$’s satisfy the assumptions of Theorem 2.8 is a direct consequence of the assumptions and Lemma 4.2. Now pick $\tilde{\mu}_0 \in \mathcal{P}(X \times \mathbb{R}^N)$ with bounded support and such that $\tilde{\mu}_0 \leq Cm \times \mathcal{L}^N$ for some $C > 0$ and for $s \in \mathbb{R}$ define

$$\tilde{\mu}_s := (\text{Fl}_s^{(\Psi(v_s))})_* \tilde{\mu}_0 \in \mathcal{P}(X \times \mathbb{R}^N) \quad \text{and} \quad \mu_s := T_s \tilde{\mu}_s \in \mathcal{P}(X).$$

We claim that $(\mu_s)$ solves the continuity equation with vector fields $(v_s)$ in the sense of Definition 2.9 and start observing that, locally in $s$, the measures $\tilde{\mu}_s, \mu_s$ have uniformly bounded density. Now pick $f \in W^{1,2}(X)$, so that $f \circ T \in W^{1,2}_{\text{loc}}(X \times \mathbb{R}^N)$ and, from Proposition 2.7, $s \mapsto \int f \, d\mu_s = \int f \circ T \circ (\text{Fl}_s^{(\Psi(v_s))}) \, d\tilde{\mu}_0$ is Lipschitz with

$$\frac{d}{ds} \int f \, d\mu_s = \frac{d}{ds} \int f \circ T \circ (\text{Fl}_s^{(\Psi(v_s))}) \, d\tilde{\mu}_0$$

by Proposition 2.7

$$= \int d(f \circ T)(\Psi(v_s)) \circ (\text{Fl}_s^{(\Psi(v_s))}) \, d\tilde{\mu}_0$$

$$= \int d(f \circ T)(\Psi(v_s)) \, d\tilde{\mu}_s$$

by (4.3.8)

$$= \int d f(v_s) \circ T \, d\mu_s$$

$$= \int d f(v_s) \, d\mu_s.$$

This proves our claim. Hence by the representation formula in Theorem 2.10 we deduce that

$$T_s \left(\text{Fl}_s^{(\Psi(v_s))}\right)_* \tilde{\mu}_0 = \left(\text{Fl}_s^{(v_s)}\right)_* T_s \tilde{\mu}_0 \quad \forall s \in \mathbb{R}$$

and from the arbitrariness of $\tilde{\mu}_0$ and (3.3.1) identity (4.3.11) follows.

To prove (4.3.12) pick $\tilde{\mu}_0, f$ and define $\tilde{\mu}_s$ as above. Then we also put

$$v_s := \pi^X_s \tilde{\mu}_s \in \mathcal{P}(X) \quad \forall s \in \mathbb{R}$$

and notice that again the $v_s$’s have, locally in $s$, uniformly bounded densities and that it holds

$$\frac{d}{ds} \int f \, dv_s = \frac{d}{ds} \int f \circ \pi^X \, d\tilde{\mu}_s = \int d(f \circ \pi^X)(\Psi(v_s)) \, d\tilde{\mu}_s$$

$$= \int \Phi_1(\hat{d}f)(\Psi(v_s)) \, d\tilde{\mu}_s = 0,$$

where as usual $\hat{d}f \in L^0(\mathbb{R}^N, L^0(T^*X))$ is the function identically equal to $d f$ and the last identity follows from (3.2.16) and the very definitions of $\Psi(v_s)$ and $Y_i$. This shows that $(v_s)$ solves the continuity equation (2.3.11) with 0 vector fields, hence by the uniqueness of the solutions we deduce that $(v_s)$ is constant, i.e.

$$\pi^X_s (\text{Fl}_s^{(\Psi(v_s))})_* \tilde{\mu}_0 = \pi^X_s \tilde{\mu}_0,$$

so that again the arbitrariness of $\tilde{\mu}_0$ and (3.3.1) give (4.3.12).

For (4.3.13), we notice that the two sides agree for $s = 0$ and are absolutely continuous as functions of $s$ with values in $L^2_{\text{loc}}(X \times \mathbb{R}^N)$ (recall Proposition 2.7). The conclusion then follows recalling that it holds $\nabla(\pi^Y \circ \pi^X) = Y_i$, so that

$$\frac{d}{ds} \pi^i \circ \pi^N \circ \text{Fl}_s^{(\Psi(v_s))} = d \left(\pi^i \circ \pi^N\right)(\Psi(v_s)) \circ \text{Fl}_s^{(\Psi(v_s))} = (Y_i, \Psi(v_s)) \circ \text{Fl}_s^{(\Psi(v_s))}$$

$$= (v_s, X_i) \circ T \circ \text{Fl}_s^{(\Psi(v_s))} \quad \text{(4.3.11)} \quad (v_s, X_i) \circ \text{Fl}_s^{(v_s)} \circ T = \frac{d}{ds} A_{i,s} \circ T.$$

Springer
This is sufficient to conclude.

We can now state the main result of the section:

**Proposition 4.4** (Representation formula for $\text{Fl}^{(v)}$) With the same assumptions and notation as in Sect. 4.1, let $(v_t) \in L^\infty([0, 1], L^2(TX)) \cap L^2([0, 1], W^{1,2}_C(TX))$ be such that $(\text{div}(v_t)) \in L^\infty([0, 1], L^\infty(X))$ and define the functions $A_{i,t} \in L^2(X)$ as in (4.3.10).

Then for any $s \in [0, 1]$ and $m$-a.e. $x \in X$ it holds

$$\text{Fl}^{(v)}_s(x) = T(x, A_s(x)),$$

where $A_s := (A_{1,s}, \ldots, A_{N,s})$.

**Proof** The identities (4.3.12), (4.3.13) give

$$\text{Fl}^{(v)}_t(x, a) = (x, a + A_t(T(x, a))) \quad m \times \mathcal{L}^N - a.e. \ (x, a).$$

Applying $T$ on both sides and taking into account (4.3.11) and (4.2.4) we obtain

$$\text{Fl}^{(v)}_t(T(x, a)) = T(T(x, a), A_t(T(x, a))) \quad m \times \mathcal{L}^N - a.e. \ (x, a).$$

Thus for any $A \subset \mathbb{R}^N$ Borel we have that (4.3.14) holds for $T_A(m \times \mathcal{L}^N |_A)$-a.e. $x \in X$ and the conclusion follows from (4.2.7). $\square$

**4.4 Further properties of $T$ and conclusion**

We shall need the following result, proved in [22], about $W_2$-geodesics and continuity equation. Recall that a measure $\pi \in \mathcal{P}(C([0, 1], X))$ is called *lifting* of the geodesic $(\mu_t)$ provided

$$(e_t)_*\pi = \mu_t \quad \forall t \in [0, 1],$$

and that, on an $\text{RCD}^*(K, N)$ space, as soon as either $\mu_0$ or $\mu_1$ is absolutely continuous w.r.t. $m$, there is a unique geodesic connecting them and a unique lifting of it (see [24]).

**Proposition 4.5** Let $(X, d, m)$ be a $\text{RCD}^*(K, N)$ space and $(\mu_t) \subset \mathcal{P}(X)$ be a $W_2$-geodesic such that $\mu_0, \mu_1$ have both bounded support and density. Then there are vector fields $(v_t) \subset L^2(X)$ such that:

(i) the continuity equation (2.3.11) is satisfied for $(\mu_t, v_t)$ in the sense of Definition 2.9

(ii) letting $\pi \in \mathcal{P}(C([0, 1], X))$ be the lifting of $(\mu_t)$ it holds

$$|v_t|(\gamma_t) = |\dot{\gamma}_t| \quad \pi \times \mathcal{L}^1 - a.e. \ (\gamma, t),$$

(iii) $v_t \in H^{1,2} \cap D(\text{div})(X)$ for every $t \in (0, 1)$ and for every $\varepsilon \in (0, 1/2)$ it holds

$$\int_\varepsilon^{1-\varepsilon} \|\nabla v_t\|_{L^2(X)}^2 \, dm + \sup_{\varepsilon \in (0, 1-\varepsilon)} (\|v_t\|_{L^\infty(X)} + \|\text{div}(v_t)\|_{L^\infty}) < \infty$$

**Proof** The vector fields $v_t$ are obtained as gradients of solutions $\eta_t$ of a double obstacle problem, the obstacles being given by appropriate ‘forward’ and ‘backward’ Kantorovich potentials, see Theorem 3.13 in [22]. This grants that (i) holds. Then (ii) is a general property of ‘optimal’ lifting of solutions of the continuity equation (see e.g. [17]). The estimates in (iii) are the main gain from [22]: the Laplacian comparison for the squared distance and the
Lewy–Stampacchia inequality grant the claimed uniform control on \( \text{div}(v_t) = \Delta \eta_t \). With a cut-off procedure based on the fact that \( \mu_0, \mu_1 \) are assumed to have bounded support, one can show that the \( \eta_t \)'s can be chosen to also have uniformly bounded support: this and the \( L^\infty \)-bound on the Laplacian implies an \( L^2 \)-bound on the Laplacian itself, so that from (2.2.6) we get the \( L^2 \)-control on \( |\nabla v_t|_{\text{HS}} = |\text{Hess} (\eta_t)|_{\text{HS}} \). Finally, in [22] it has been proved that the \( \eta_t \)'s are Lipschitz and, although not explicitly mentioned, keeping track of the various constants involved one can see that it is provided a uniform control on the Lipschitz constant for \( t \in (\varepsilon, 1 - \varepsilon) \), which in turn implies the desired \( L^\infty \) control on \( |v_t| \).

Thanks to this result we can now prove the following crucial statement:

**Proposition 4.6** With the same notations and assumptions as in Sect. 4.1 the following holds. For every \( x, y \in X \) there exists \( a \in \mathbb{R}^N \) such that

\[
T(x, a) = y \quad \text{and} \quad |a| \leq d(x, y).
\]

**Proof** Fix \( y \in X, R > 0 \), define

\[
\mu_0 := m(B_R(y))^{-1} m_{|B_R(y)} \quad \mu_1 := \delta_y
\]

and let \( (\mu_t) \) be the unique \( W_2 \)-geodesic connecting \( \mu_0 \) to \( \mu_1 \) and \( \pi \) its lifting. Also, fix \( \varepsilon \in (0, 1/2) \). Then we know from [24] that the \( W_2 \)-geodesic \( t \mapsto \mu^\varepsilon_t \) satisfies the assumptions of Proposition 4.5 and that its lifting \( \pi^\varepsilon \) is given by

\[
\pi^\varepsilon = (\text{Restr}_{1-\varepsilon})_\pi \pi,
\]

where \( \text{Restr}_{1-\varepsilon} : C([0, 1], X) \rightarrow C([0, 1], X) \) is given by

\[
\text{Restr}_{1-\varepsilon} (\gamma) \begin{array}{l} \gamma(t) = \gamma((1-t)0 + t \pi) \quad \forall \gamma \in C([0, 1], X). \end{array}
\]

Up to pass to a further restriction, Proposition 4.5 grants the existence of vector fields \( (v^\varepsilon_t) \) satisfying (i), (ii), (iii) in the statement. In particular, by (iii) we know that the assumptions of Theorem 2.8 are satisfied so that there exists the Regular Lagrangian Flow \( (\text{Fl}_{x}^{(v^\varepsilon_t)}) \) of \( (v^\varepsilon_t) \).

The representation formula for the solutions of the continuity equation given in Theorem 2.10 gives

\[
\mu^\varepsilon_s = \left( \text{Fl}_{x}^{(v^\varepsilon_t)} \right) \star \mu^\varepsilon_0, \quad \forall s \in [0, 1].
\]

Therefore using the trivial inequality

\[
|A^\varepsilon_t|^2 = \sum_{i=1}^{N} |A^\varepsilon_{i, t}|^2 \leq \sum_{i=1}^{N} \int_0^1 \left( (v^\varepsilon_s, X_i)^2 \right) \text{Fl}_{x}^{(v^\varepsilon_t)} ds = \int_0^1 |v^\varepsilon_s|^2 \circ \text{Fl}_{x}^{(v^\varepsilon_t)} ds \leq R^2
\]

valid \( \mu^\varepsilon_0 \)-a.e. in conjunction with (4.4.3) we deduce that for \( \mu^\varepsilon_0 = \mu^\varepsilon_0 \)-a.e. \( x \)

there exists \( a \in \mathbb{R}^N \) with \( |a| \leq R \) such that \( d(T(x, a), y) \leq \varepsilon R \)

\[
(4.4.5)
\]
and an argument based on the continuity of $T$ and the compactness of $B_R(0) \subset \mathbb{R}^N$ yields that the same holds for any $x \in \text{supp}(\mu_\epsilon)$.

Now notice that simple considerations about the structure of $W_2$-geodesics grant that the Hausdorff distance between $\text{supp}(\mu_0) = B_R(y)$ and $\text{supp}(\mu_\epsilon)$ is bounded above by $\epsilon R$, thus for $x \in B_R(y)$ there is a sequence $n \mapsto x_n \in \text{supp}(\mu_{1/n})$ converging to $x$. Let $a_n$ be given by (4.4.5) for $x := x_n$ and $\epsilon := \frac{1}{n}$: by the uniform bound $|a_n| \leq R$ and up to pass to a non-relabeled subsequence we can assume that $a_n \to a$ for some $a \in \mathbb{R}^N$ with $|a| \leq R$. Passing to the limit in

$$d(T(x_n, a_n), y) \leq \frac{R}{n}$$

using the continuity of $T$ we conclude that $T(x, a) = y$. By the arbitrariness of $x \in B_R(y)$ and of $R > 0$ the proof is completed. \hfill \Box

Let us now fix a point $\bar{x} \in X$ and denote by $G \subset \mathbb{R}^N$ its stabilizer, i.e.

$$G := \{ a \in \mathbb{R}^N : T(\bar{x}, a) = \bar{x} \}. \quad (4.4.6)$$

Notice that the last proposition (and the commutativity of $\mathbb{R}^N$) grants that the stabilizer does not depend on the choice of the particular point $\bar{x}$; moreover $G$ is a subgroup of $\mathbb{R}^N$ which, by the continuity of $T$, is closed.

**Proposition 4.7** With the same notations and assumptions as in Sect. 4.1 the following holds. The subgroup $G$ of $\mathbb{R}^N$ defined in (4.4.6) is discrete.

**Proof** It is well known that closed subgroups of $\mathbb{R}^n$ either contain a line or are discrete (see e.g. [14]). We then argue by contradiction: if it is not discrete it must contain a line so that for some $a = (a_1, \ldots, a_N) \neq 0$ in $\mathbb{R}^N$ we have $ta \in G$ for every $t \in \mathbb{R}$. Put $X := \sum_{i=1}^N a_i X_i$ and notice that $X$ is not identically 0 and harmonic, so that its Regular Lagrangian Flow $(Fl_t^X)$ consists of measure preserving isometries of $X$ such that for $m$-a.e. $x$ the curve $t \mapsto Fl_t^X(x)$ has constant positive speed (recall (2.3.3)). In particular, for $m$-a.e. $x$ such curve is not constant.

On the other hand, the very definition of $T$ yields

$$T(x, ta) = Fl_t^X(x) \quad \forall x \in X, \ t \in \mathbb{R}$$

and by assumption the left hand side is equal to $x$ for every $t$: this gives the desired contradiction and the conclusion. \hfill \Box

The quotient space $\mathbb{R}^N/G$ is equipped with the only Riemannian metric letting the quotient map be a Riemannian submersion. The distance induced by this metric is

$$d_{\mathbb{R}^N/G}([a], [b]) = \min_{\substack{a' | [a'] = [a] \\ b' | [b'] = [b]}} |a' - b'|. \quad (4.4.7)$$

Also, $\mathbb{R}^N/G$ comes with a canonical, up to multiplication with a positive constant, reference measure $m_{\mathbb{R}^N/G}$: the Haar measure, which also coincides with the volume measure induced by the metric.

Finally, the map $T$ passes to the quotient and induces a map $\tilde{T} : \mathbb{R}^N/G \to X$ via the formula:

$$\tilde{T}([a]) := T(\bar{x}, a).$$
With this said, we can now conclude the proof of our main result:

**Theorem 4.8** With the same notations and assumptions as in Sect. 4.1 the following holds.

(i) The subgroup $G$ of $\mathbb{R}^N$ defined in (4.4.6) is isomorphic to $\mathbb{Z}^N$, so that the quotient space $\mathbb{R}^N/G$ is a flat torus $\mathbb{T}^N$.

(ii) The induced quotient map $\tilde{T}: \mathbb{T}^N \to X$ is an isometry such that $\tilde{T}_* m_{\mathbb{T}^N} = cm$ for some $c > 0$.

**Proof** $\tilde{T}$ is an isometry From (4.2.6) and the definition (4.4.7) we get

$$d(\tilde{T}([a]), \tilde{T}([b])) \leq d_{\mathbb{R}^N/G}([a], [b]) \quad \forall [a], [b] \in \mathbb{R}^N/G. \quad (4.4.8)$$

Now let $a, b \in \mathbb{R}^N$, put $x := \tilde{T}([a])$, $y := \tilde{T}([b])$ and apply Proposition 4.6 to find $c \in \mathbb{R}^N$ such that $\tilde{T}(x, c) = y$ and $|c| \leq d(x, y)$. Since we have

$$\tilde{T}([a + c]) = T(x, a + c) \quad (4.2.4) \quad T(T(x, a), c) = T(x, c) = y,$$

we see that $[a + c] = [b]$ and thus

$$d_{\mathbb{R}^N/G}([a], [b]) \leq |c| \leq d(x, y),$$

which together with (4.4.8) shows that $\tilde{T}: \mathbb{R}^N/G \to X$ is an isometry.

Up to a multiplicative constant, $\tilde{T}$ is measure preserving Being an isometry, $\tilde{T}$ is invertible: denote by $S: X \to \mathbb{R}^N/G$ its inverse and put $\mu := S_* m$. For $a = (a_1, \ldots, a_N) \in \mathbb{R}^N$ let $X_a := \sum_{i=1}^N a_i X_i$ and notice that (4.2.4) reads as $T(\bar{x}, b + a) = F_1(X_a)(T(\bar{x}, b))$ for every $a, b \in \mathbb{R}^N$. Passing to the quotient we obtain

$$\tilde{T}([b] + [a]) = F_1(X_a)(\tilde{T}([b])) \quad \forall a, b \in \mathbb{R}^N, \quad (4.4.9)$$

hence letting $\tau[a]: \mathbb{R}^N/G \to \mathbb{R}^N/G$ be the translation by $[a]$ defined by $\tau[a]([b]) := [b] + [a]$ we can rewrite (4.4.9) as

$$\tau[a] \circ S = S \circ F_1(X_a) \quad \forall a \in \mathbb{R}^N. \quad (4.4.10)$$

Therefore we have

$$\tau[a]_* \mu = \tau[a]_* S_* m \quad (4.4.10) = S_* (F_1(X_a))_* m \quad (3.3.3) = S_* m = \mu \quad \forall a \in \mathbb{R}^N.$$

This shows that $\mu$ is translation invariant and thus a multiple of the Haar measure $m_{\mathbb{R}^N/G}$.

$G = \mathbb{Z}^N$ and conclusion What we just proved and (4.1.1) ensure that $m_{\mathbb{R}^N/G}$ is a finite measure. Now recall that discrete subgroups of $\mathbb{R}^N$ are isomorphic to $\mathbb{Z}^n$ for some $n \leq N$ (see e.g. [14]) and that $\mathbb{R}^N/\mathbb{Z}^n$ has finite volume if and only if $n = N$. Being $G$ discrete (Proposition 4.7), the thesis follows. \qed
