**Abstract**—The disinfection of recirculating nutrient solution is essential to avoid disasters due to the dispersal of pathogens in a closed soilless culture system. In this work, a disinfection technique using pulsed electric field (PEF) has been investigated. A system was designed to implement continuous disinfection treatment of nutrient solution. The system mainly includes two parts: 1) a pulsed power generator that produces repetitive pulses with amplitude of between 0 kV and 5 kV with a pulse duration of 10 μs and a pulse repetition frequency of 50 Hz and 2) a parallel-plate treatment chamber used to realize continuous processing. In order to verify the efficacy of PEF treatment *Fusarium oxysporum*, being amongst the most destructive root-borne diseases, was selected as the object of study and therefore the nutrient solution was inoculated with this pathogen. The results indicate that PEF treatment deactivates most of the *Fusarium oxysporum* in the nutrient solution, achieving a maximum disinfection efficiency of 99%. At the same time, no obvious changes of the inorganic compositions in the PEF-treated nutrient solution were observed. The overall system is simple and convenient to be operated, worked stably and was capable of achieving a continuous treatment. This work therefore clearly demonstrates the feasibility of continuous PEF disinfection treatment in real soilless culture systems, opening the door for implementation in various agricultural applications.

**Keywords**—pulsed electric field, nutrient solution, *Fusarium oxysporum*, sterilization, soilless culture system

I. INTRODUCTION

The recycling of nutrient solutions in soilless culture systems may not only greatly save water and fertilizer but also reduce pollution on rivers and groundwater. However, there is a risk that root-borne diseases could affect closed systems, as pathogens may rapidly spread through recycling nutrient solution and lead to plant infection and even devastating losses [1, 2]. Therefore, placing an in-situ disinfecting nutrient solution is essential. Several methods have been applied for the disease control in recirculating soilless culture systems such as: ozone, ultraviolet, filtration, chemical sterilization and radiation and biological control [3-8].

Even though ozone disinfection is commonly used, studies indicated that the inactivation ability of ozonized water for *Fusarium oxysporum* conidia will diminish when the concentration of ozone in water is below 0.1 ppm [9]. Besides, for the low solubility in water (0.105 g/100 ml at 0 ºC), a significant percentage of ozone may escape from the solution, creating hazard pollution for both people and plants. Applying UV radiation is another important disinfection technique, but to maintain its efficacy it requires the transparency of nutrient solution to be at least 60% [10]. Moreover, the limited lifetime of UV lamps indirectly increases the cost of equipment. Although the chemical treatment could achieve satisfactory efficacy, the residues also raise concerns for consumers. Therefore, it is desired to develop a safe and effective alternative disinfection method.

The application of pulsed electric field (PEF) has been widely reported in food engineering. Numerous studies indicated that PEF technology is an effective non-thermal sterilization method for liquid food [11]. The commonly accepted mechanism of PEF treatment is electroporation on the cell membrane of the pathogen [12, 13]. Compared to traditional sterilization technologies, PEF has several attractive advantages: higher efficiency in breaking the cell membrane, thorough disinfection, quick treatment, lower temperature rise and therefore less energy consumption [14]. Hence, PEF has the potential to act as an alternative nutrient solution disinfection technique for a closed soilless culture system.

Our previous work presented that by the use of PEF treatment, the maximum disinfection efficiency of *Fusarium oxysporum* in a nutrient solution could reach 99.84% within a few seconds of application [15]. However, the process was static and therefore unable to treat the nutrient solution while in a continuous flow. Additionally, the pulsed generator then used included a spark gas switch which had a short service life and was therefore not practical in real applications.

To demonstrate continuous disinfection of nutrient solution by the PEF technique, a pulsed power generator equipped with a high-voltage semiconductor switch (thyristor) and a novel corresponding treatment chamber were both developed. Several experiments were conducted to show its potential for future practical applications.

II. MATERIALS AND METHODS

A. Preparation of plant pathogenic fungal and suspensions

*Fusarium oxysporum* was used as the target fungal to evaluate disinfection performance, which was preserved and provided by the college of plant protection, China Agricultural University. *Fusarium oxysporum* was cultured on potato dextrose agar (PDA) in an incubator at 28 ºC for 5 days. Several mycelial plugs from the edge of the colony were
transferred to 250 mL flasks containing potato dextrose broth (PDB) and incubated at 28°C on a rotary shaker at a speed of 160 r/min. After 5 days, the liquid was passed through two layers of sterile cheesecloth to filter out tiny fragments of hyphae. The microconidia were counted under a microscope at 1.0 × 10^7 spores/mL using a hemocytometer [16]. The fungal solutions were suspended in a hydroponic nutrient solution (approximately 1.0×10^5 spores/mL or CFU/mL), which was composed of 370 mg/L potassium nitrate, 115 mg/L ammonium dihydrogen phosphate, 483 mg/L magnesium sulfate, 820 mg/L calcium nitrate, 25 mg/L mixed trace elements, respectively. The pH and electrical conductivity (EC) of the nutrient solution were 6.6 and 1.7 mS/cm, respectively.

B. PEF treatment system

Fig. 1 demonstrates the experimental arrangement, which consists of a HV pulsed power generator, a treatment chamber, and the necessary monitoring and controlling devices.

Fig. 2 shows the circuit of the HV pulsed power generator, which was designed to generate microsecond output voltage pulses to the load \( R_L \), i.e., the equivalent resistance of the treatment chamber. The AC power (220 V, 50 Hz) is boosted by a HV transformer. The capacitor \( C \) is charged via a diode \( D \) in the positive half cycle of voltage and discharged in the negative half cycle. A high-voltage thyristor (5STP08F6500, ABB) is used to switch pulses. A weak underdamped voltage waveform is necessary to maintain the reliable turn-off operation of the thyristor, with the relationship among \( R_L, L \) and \( C \) being given by (1), and the inductance \( L \) and capacitance \( C \) being 11.5 \( \mu \)H and 305 nF, respectively. Consequently, the \( R_L \) is 9.8 \( \Omega \).

\[ R_L = \frac{L}{6\sigma A} \]  

(1)

Fig. 3 displays a typical waveform of the pulsed voltage applied to the treatment chamber, measured by a high-quality HV probe (1000:1, P6015A, Tektronix, USA) connected to a digital oscilloscope (TDS2012C, Tektronix, USA). The pulse has a duration approximately equal to 10 \( \mu \)s and a repetition frequency of 50 Hz. For parallel plate electrodes placed a small distance \( d \) apart, the strength of the pulsed electric field can be simply calculated using (2), with the output voltage amplitude \( U \) of the generator adjusted between 0 to 5 kV, corresponding to an electric field strength \( E \) ranging from 0 to 18.5 kV/cm.

\[ E = \frac{U}{d} \]  

(2)

Fig. 4. Details of the PEF treatment chamber.
Fig. 4 shows the cross-section of the PEF treatment chamber consisting of two parallel mounted stainless steel electrodes placed a distance $d = 2.7$ mm apart using an acrylic spacer, with the electrodes and the spacer fixed using plastic screws and nuts. The electrodes are 240 mm long and 49 mm wide. Nutrient solution flows through the channel (blue area in Fig. 4) in the acrylic spacer with a volume of 5.52 mL.

C. Energy consumption

The energy consumption of a PEF treatment is one of the most important parameters which depends on the electric field strength and the length of the pulse, as well as the number of pulses [17].

The energy delivered in each pulse is given by:

$$W_p = \int_0^{t_p} \frac{u(t)^2}{R_L} \, dt$$  \hspace{1cm} (4)

where $u(t)$ is the time-varying voltage applied to the electrodes, $R_L$ is the resistance of the test object and $t_p$ is the pulse duration. The total applied energy is simply obtained by multiplying $W_p$ with the number of the pulses.

D. Measurement of surviving spores and cells

The number of surviving *Fusarium oxysporum* spores was evaluated by colony counting method and measured by plating 0.1 mL of each sample and serially diluted sample with a sterilized 0.9 wt% NaCl aqueous solution onto PDA. This procedure was performed on a clean bench to prevent unwanted bacteria pollution. The plates were incubated at 28 °C for 36 h. After the incubation, the plates with 30 – 300 spores or CFU were chosen to count the colonies [18]. The detection limit was 1 spore/mL or CFU/mL. The disinfection efficiency $\delta$ (%) was calculated by (5).

$$\delta(\%) = \frac{N_0 - N}{N_0} \cdot 100\%$$  \hspace{1cm} (5)

where $N_0$ and $N$ are the colony numbers of *Fusarium oxysporum* before and after the PEF treatment, respectively.

E. Measurement of inorganic compositions in the hydroponic nutrient solutions

The same hydroponic nutrient solution as described above was used. The PEF treatment was performed applying a peak electric field strength 14 kV/cm with a flow rate of 0.3, 1 and 2 L/min, respectively, these being the most severe parameters of all the conditions tested. The concentrations of nitrate-nitrogen and available potash in the hydroponic nutrient solutions before and after PEF treatment were analyzed by a spectrophotometer (UV-3150) and an atomic absorption spectrophotometer (AA-7000), respectively.

All experiments were performed in triplicate.

III. RESULTS AND DISCUSSION

A. Influence factors of PEF on the sterilization effect of *Fusarium oxysporum* in nutrient solution

Many factors are affecting the efficiency of PEF treatment on microorganisms, with the most important being the peak electric field strength and the treatment time. In this study, the influence of these two factors on the sterilization efficiency is analysed in detail. The processing time varies with the flow rate and the effect of the flow rate on the disinfection efficiency is presented in Fig. 5.

As Fig. 5 shows, the disinfection efficiency decreases with an increase of the flow rate. This is because the increase of flow rate decreases the number of pulses applied to the nutrient solution per unit time. When the peak electric field strength was 17.04 kV/cm and the flow rate was only 0.3 L/min, the disinfection efficiency of *Fusarium oxysporum* reached 99%.

B. Effect of PEF treatment on inorganic compositions in nutrient solution

Fig. 7 shows the test results of the inorganic composition in nutrient solution after PEF treatment under different flow rates at a peak electric field strength of 14 kV/cm. The results indicate the compositions of nitrate-nitrogen and available potash in the nutrient solution have a negligible change. This clearly demonstrates the advantage of the PEF treatment technique that can efficiently implement disinfection without obviously changing the nutrient solution, which is friendly to all practical soilless culture planting.
C. Analysis of energy consumption

As can be seen from Fig. 8, the energy efficiency varied inversely to the strength of the peak electric field strength and positively proportional to the flow rate. For an applied peak electric field strength of 11.26 kV/cm and with the nutrient solution flow rate 0.3 L/min, the sterilization rate was 95% with the corresponding energy consumption being between 159.59 L/kWh and 173.26 L/kWh.

Fig. 8. Energy efficiency under different field strength and flow rate.

IV. CONCLUSION

In this work, a prototype of a PEF disinfection was developed, which allows a continuous treatment of nutrient solution. Based on a highly efficient HV thyristor closing switch, the pulsed power generator was capable of stable operation at a pulsed repletion frequency of 50 Hz. Significant disinfection efficiency of *Fusarium oxysporum* in the nutrient solution was observed during experiments. By applying peak electric field strength as high as 17.04 kV/cm while maintaining a flow rate of 0.3 L/min, the disinfection rate was 95%.

The results obtained are consistent with the studies of other scholars. Very importantly, after the PEF treatment there were no obvious changes in the composition of nitrate-nitrogen and available potassium in the nutrient solution. When the disinfection rate was 95%, the energy efficiency was between 159.59 L/kWh and 173.26 L/kWh. This work clearly demonstrates the feasibility and potentiality of continuous PEF disinfection equipment utilized for various future real soilless culture system applications.
