ABSTRACT: We derive the classical gravitational radiation from an aligned spin binary black hole on closed orbits, using a dictionary built from the 5-point QFT scattering amplitude of two massive particles exchanging and emitting a graviton. We show explicitly the agreement of the transverse-traceless components of the radiative linear metric perturbations – and the corresponding gravitational wave energy flux – at future null infinity, derived from the scattering amplitude and those derived utilizing an effective worldline action in conjunction with multipolar post-Minkowskian matching. At the tree-level, this result holds at leading orders in the black holes’ velocities and up to quadratic order in their spins. At sub-leading order in black holes’ velocities, we demonstrate a matching of the radiation field for quasi-circular orbits in the no-spin limit. At the level of the radiation field, and to leading order in the velocities, there exists a one-to-one correspondence between the binary black hole mass and current quadrupole moments, and the scalar and linear-in-spin scattering amplitudes, respectively. Therefore, we show explicitly that waveforms, needed to detect gravitational waves from inspiraling binary black holes, can be derived consistently, to the orders considered, from the classical limit of quantum scattering amplitudes.
1 Introduction

In the early days of general relativity, Einstein predicted the existence of gravitational waves [1] and cast the emission from a compact system into the, now famous, Quadrupole formula for gravitational radiation. A little while later, in a spectacular breakthrough the LIGO/Virgo Collaboration [2] confirmed Einstein’s prediction by directly detecting the gravitational waves emitted from a binary black hole (BBH). Higher order corrections to Einstein’s Quadrupole formula in the context of the quasi-circular orbit general relativistic two-body problem – needed to enable such detections – have traditionally been obtained in the post-Newtonian (PN) [3, 4] formalism, within numerical relativity [5] and black hole perturbation theory [6, 7], as well as models combining these approaches [8–10]. More recently, however, efforts have been focused on the BBH scattering problem, in order to connect classical computations performed in the context of post-Minkowskian (PM) theory [11–24], with those approaches based on the classical limit of QFT scattering amplitudes [25–46].

Until recently, the scattering amplitudes approach to the two-body scattering problem had mostly focused it’s efforts in the conservative sector, although hints from soft theorems suggest that they can also be used to address the radiative sector [47–49]. The introduction of the Kosower, Maybee and O’Connell (KMOC) formalism [50], enabling the computation of classical observables directly from the scattering amplitude, proved to be extremely useful in determining radiative observables. Using this formalism, an amplitudes derivation of the waveform from hyperbolic, soft encounters was presented in [51], encapsulating the gravitational memory content of the signal [52]. In this same formalism, the computation of the full leading PM order radiated four-momentum was recently presented in [53, 54]; these results were subsequently confirmed by other methods in [55–57]. Simultaneously, using a worldline-QFT formalism [58], the computation of the gravitational waveform valid for all values for the momentum of the emitted graviton, was computed in [59] (see also [60]), and extended to include spin effects in [61]. Analogously, the scattering amplitudes approach has been employed to study radiation scattering off of a single massive source [62, 63], where a novel connection between scattering amplitudes and black hole perturbation theory has emerged [64], shedding light on how to obtaining the higher-spin gravitational Compton amplitude [65] (see also [66, 67]).

Even with the powerful scattering amplitudes techniques at hand, so far, radiative information from bodies moving on bounded orbits has been obtained only via analytic continuation [18, 19] of radiation observables of scattering bodies [53, 68, 69] (applying mainly in the large eccentricity limit). However, the almost 40 year old derivation of the Einstein quadrupole formula from a Feynman diagrammatic perspective by Hari Dass and Soni [70], and the more recent derivation by Goldberger and Ridgway using the classical double copy [13], suggest that scattering amplitudes can indeed be used to derive gravitational radiation emitted from objects moving on general closed orbits (including the zero eccentricity limit, i.e., quasi-circular orbits). In this work we follow this philosophy to compute the gravitational waveform emitted from an aligned spin BBH on general and quasi-circular orbits, up to quadratic order in the constituents spin at the leading order in the velocity.
expansion and to sub-leading order in the no-spin limit, from a 5-pt scattering amplitude of two massive particles exchanging and emitted gravitons. We contrast and compare these results to the analogous classical derivation of the corrections to the Einstein quadrupole formula using the well-established multipolar post-Minkowskian formalism [3, 71–74].

We find perfect agreement between the classical and the scattering amplitudes derivation of all radiative observables we consider, to the respective orders in the spin and velocity expansions. Furthermore, we show that at leading order in the BBH velocities, there is a one-to-one correspondence between the BBH source’s mass and current multipole moments, and the scalar and linear-in-spin 5-pt scattering amplitude, respectively. At quadratic order in the BHs’ spin, we demonstrate explicitly that the corresponding contribution from the quadratic-in-spin scattering amplitude does not provide additional spin information at the level of the waveform; hence, we conjecture this to hold for higher-spin amplitudes as well, based on the aforementioned correspondence. Then, the leading in velocity, all orders-in-spin waveform, is obtained purely through the solutions to the equations of motion (EoM) of the conservative sector of the BBH. Furthermore, the gauge dependence of gravitational radiation information at future null infinity is a potential source of difficulty when comparing results obtained by different approaches. In this work, we provide evidence that gauge freedom partially manifests itself in the integration procedure appearing in the computation of the waveform directly from the scattering amplitude. For quasi-circular orbits, the orbit’s kinematic variables are subject to certain relations, such that the gravitational waveform can take different forms without affecting the gauge invariant information contained in the total instantaneous gravitational wave energy flux.

This paper is organized as follows: In §2, we begin by reviewing the classical derivation of the conservative sector of the spinning BBH to all orders in the spins at leading PN. In §2.2, we derive the associated gravitational wave emission from this system to all order in the BHs’ spins. We then proceed with the scattering amplitudes derivation of the waveform in §3, with the general formalism outlined in §3.1. In §3.2 we present the relevant scattering amplitudes needed for the computation, obtained only through the Compton and the 3-pt amplitudes, and subsequently use them in §3.3 for explicitly determining the waveform. In section §3.4, we briefly discuss the computation of the gauge invariant energy flux, and comment on the manifestation of the gauge freedom. We conclude with a discussion in §4.

In this paper we use Greek letters $\alpha, \beta, \ldots$ for spacetime indices and Latin letters $i, j, \ldots$ for purely spatial indices. Furthermore, we use $G = c = 1$ units throughout, assume $\varepsilon_{0123} = 1$, and use the $2\nabla_{[\alpha} \nabla_{\beta]} \omega_{\mu} = R_{\alpha\beta\mu\nu} \omega_{\nu}$ Riemann tensor sign convention.

2 Classical derivation

In order to approach the bound orbit from a classical point of view, we utilize an effective worldline action [12, 75–80], parametrizing the complete set of spin-induced interactions of the two spinning BHs in the weak-field regime, at linear order in the gravitational constant, i.e. at PM order. As we are interested in bound, as opposed to unbound, orbits, we will be focusing on the leading PN contribution to the 1PM conservative sector at each order in the BHs’ spins. In the following, we first briefly summarize the necessary conservative
results established in Refs. [79, 81–94]. Using these results, we then tackle the radiative sector, utilizing the multipolar post-Minkowskian formalism [4, 71–74] (see also Ref. [3] and references therein). We derive the transverse-traceless (TT) pieces of the linear metric perturbations, $h_{\mu\nu}^{TT}$, and the total instantaneous gravitational wave power, $F$, radiated by this source to future null infinity. We achieve this, considering all orders in the spins, both for an aligned spin system on general orbits at leading order in velocities, as well as specialize to quasi-circular orbits at leading and first sub-leading orders in velocities. In this section, we work in the $-++$ signature for the flat metric, and set $G = 1$.

2.1 Classical spinning Binary black hole

Let us begin by briefly reviewing the approach to the conservative sector of the BBH dynamics at the respective orders in the weak-field and low-velocity regimes using an effective worldline action. In sec. 2.1.1 we present the necessary spin-interactions to describe a rotating BH, while in sec. 2.1.2 we review how an effective spinning BBH action, needed for the computation of the radiation field, can be derived.

2.1.1 Effective binary black hole action

An effective description of a rotating black hole (BH), obeying the no-hair theorems, as a point particle with suitable multipolar structure in the weak-field regime rests solely on its worldline and spin degrees of freedom [12, 76, 78, 92, 95]. The former are given by a worldline $z^{\mu}(\lambda)$ of mass $m$, with 4-velocity $u^{\mu} = dz^{\mu}/d\lambda$, while the latter are encoded in the BH’s (mass-rescaled) angular momentum vector $a^{\mu}$, and local frame $e_{A}^{\mu}(\lambda)$. An effective worldline action, $S$, that entails the dynamics of such a BH (or, more generally, a compact object) in the weak-field regime was developed in Refs. [75–79]; see Ref. [80] for further details. This action $S[h, K]$, describing a rotating compact object, is built considering all possible couplings of gravitational, $h = \{h_{\mu\nu}\}$, and object specific degrees of freedom, $K = \{z^{\mu}, u^{\mu}, a^{\mu}, e_{A}^{\mu}\}$, requiring covariance, as well as reparameterization and parity invariance [78, 80, 96, 97]. At the 1PM level, a matching procedure between the linearized Kerr metric [93, 98, 99] and the gravitational field $h_{\mu\nu}$, emanating from a generic compact object described by $S[h, K]$, leads to a unique set of non-minimal couplings between $h$ and $K$. This ultimately results in an effective 1PM BH worldline action $S_{BH}[h, K]$. This action can be extended to higher orders in $G$ in spins (see for instance Refs. [100–103]).

It was shown in Ref. [99] that for a harmonic gauge linearized Kerr BH the infinite set of spin-couplings present in the 1PM effective worldline action $S_{BH}[h, K]$ can be resumed into an exponential function. In a linear setup, a BH of mass $m$ traveling along the worldline $z^{\mu}(\lambda)$, sources the gravitational field, $g_{\mu\nu} = \eta_{\mu\nu} + h_{\mu\nu}^{Kerr} + \mathcal{O}(h^{2})$, with [99]

$$h_{\mu\nu}^{Kerr} = 4\mathcal{P}_{\alpha\beta}a^{\alpha\beta}T_{Kerr}^{\alpha\beta}, \quad \mathcal{P}_{\alpha\beta} = \frac{1}{r},\quad \mathcal{P}_{\alpha\beta} = m \exp(a \ast \partial_{\mu}u_{\nu}u^{\rho}),$$

where $a^{\mu} = \varepsilon^{\mu}_{\alpha\beta\gamma}u^{\alpha}S^{\alpha\beta}/(2m)$ emerges from the spin tensor $S^{\alpha\beta}$ assuming the covariant spin supplementary condition, $p_{\mu}S^{\mu\nu} = 0$, and a local body-fixed frame $e_{A}^{\mu}(\lambda)$. See, for instance, Ref. [95] for details.
Here we define \((a \ast \partial)^{\mu}_{\nu} = \epsilon^{\mu}_{\nu\alpha\beta}a^\alpha \partial^\beta\) and introduced the trace reverser \(P_{\mu\nu\alpha\beta} = (\eta_{\mu\alpha}\eta_{\nu\beta} - \eta_{\mu\beta}\eta_{\nu\alpha})/2\). Additionally, \(\hat{r}\) labels the proper distance between the spacetime point \(x\) and the worldline \(z^\mu(\lambda)\), within the slice orthogonal to \(u^\mu\) [99]. In the following, we restrict ourselves to the leading PN part of the 1PM ansatz, since this is the natural setting for closed orbits in the weak field regime. However, while we are expanding in \(\epsilon_{\text{PN}} \sim v^2/c^2 \sim GM/rc^2\), we consider all orders in the spins, i.e., consider \(\epsilon_{\text{spin}} \sim \chi GM/rc^2\) non-perturbatively (here, \(\chi\) the black hole’s dimensionless spin parameter). To that end, we choose the Minkowski coordinate time \(t\) to parameterize the worldline \(z^\mu\), i.e., \(\lambda \rightarrow t\), and expand the 4-velocity \(u^\mu = (1, v)^\mu + \mathcal{O}(v^2)\), with \(z^i = dz^i/dt = v^i\). Given this and utilizing the three-dimensional product \((a \ast \partial)_i = \varepsilon_{ijk}a^j \partial^k\), the metric (2.1) reduces to its leading PN form:

\[
\begin{align*}
\hat{h}^0_{00}^{\text{Kerr}} &= \left(2 \cosh(a \ast \partial) - 4v_i \sinh(a \ast \partial)i^i\right) \frac{m}{\hat{r}} + \mathcal{O}(v^2), \\
\hat{h}^0_{0i}^{\text{Kerr}} &= \left(4v_i \cosh(a \ast \partial) - 2 \sinh(a \ast \partial)i^i\right) \frac{m}{\hat{r}} + \mathcal{O}(v^2), \\
\hat{h}^{ij}^{\text{Kerr}} &= \left(2\delta^{ij} \cosh(a \ast \partial) - 4v_i \sinh(a \ast \partial)j^j\right) \frac{m}{\hat{r}} + \mathcal{O}(v^2).
\end{align*}
\]  

Note that even at zeroth order in velocity, the solution contains non-trivial gravitomagnetic contributions, \(h_{ij}^{\text{Kerr}}\), due to the presence of the BH spin. Conversely, an effective stress-energy distribution \(T_{\mu\nu}\) can be derived that yields (2.2) via the linearized Einstein equations\(^2\) \(\Box h^{\text{Kerr}}_{\mu\nu} = -16\pi P_{\mu\nu}^{\alpha\beta}T_{\alpha\beta}\). This distribution has support only on the worldline \(z^i(t)\) and, with the above parameterization, is given by

\[
T_{\mu\nu}(t, x^i) = \hat{T}^{\text{Kerr}}_{\mu\nu}\delta^3(x - \hat{z}(t)) + \mathcal{O}(v^2),
\]

Collecting these within the worldline action, we can construct an effective binary BBH \(S_{\text{BBH}}\) that encodes the conservative dynamics with the complete spin information at the leading PM level [99] or leading PN level [93, 94]. That is, given two worldlines \(z_{1,2}^\mu\), with velocities \(u_{1,2}^\mu\), masses \(m_{1,2}\), and two spin vectors \(a_{1,2}^\mu\) – conveniently collected in the sets \(\mathcal{K}_{1,2}\) – the spin interactions within the binary are obtained by integrating out the gravitational field in a Fokker-type approach [104]. Following [94, 99], in practice, the effective action for the second BH \(S_{\text{BH}}[h, \mathcal{K}_2]\) (containing this BH’s degrees of freedom \(\mathcal{K}_2\)) is evaluated at the metric of the first BH \(h \rightarrow h_1\), such that \(S_{\text{BH}}[h, \mathcal{K}_2] \rightarrow S_{\text{BH}}[h_1, \mathcal{K}_2]\). However, since the metric \(h_1\), explicitly given in (2.1), is effectively a map from the gravitational degrees for freedom into that of BHs’ degrees of freedom, i.e., \(h_1 \rightarrow \mathcal{K}_1\), the BBH action \(S_{\text{BH}}[h_1 \rightarrow \mathcal{K}_1, \mathcal{K}_2] \rightarrow S_{\text{BBH}}[\mathcal{K}_1, \mathcal{K}_2]\), solely depends on the BHs’ degrees of freedom.

### 2.1.2 Conservative dynamics

In order to write out the effective BBH action \(S_{\text{BBH}}[\mathcal{K}_1, \mathcal{K}_2]\) explicitly, let us define the spatial separation \(r^i = z^i_1 - z^i_2\), with \(r = |r|\), between the two worldlines, as well as the spin \(\lambda^i\).
sums $a_+^i = a_1^i + a_2^i$ and $a_-^i = a_1^i - a_2^i$. The angular velocity tensor $\Omega_{1,2}^i$ is introduced for completeness, however, the aligned-spin dynamics are independent of $\Omega_{1,2}^i$. Finally, we define a radius of mass frame velocity $v^i = \dot{r}^i = v_1^i - v_2^i$. In Refs. [93, 94] it was shown that after integrating out the gravitational degrees of freedom, as described in the previous section, the effective BBH action $S_{BBH}$ reduces to the two-body Lagrangian

$$L_{BBH} = \left[ \frac{m_1}{2} v_1^2 + \frac{m_1}{2} \varepsilon_{ijk} a_1^i v_1^j \dot{a}_1^k + m_1 a_1^i \Omega_{1,i} + (1 \leftrightarrow 2) \right]$$

$$+ \left[ \cosh(a_+ \times \partial) + 2v_i \sinh(a_+ \times \partial)^i \right] \frac{m_1 m_2}{r},$$

at the leading PN level. Note that here and in the remainder of this section $\partial r^{-1} = \partial r^{-1}/\partial z_1^i = -\partial r^{-1}/\partial z_2^i$. So far, we have assumed a leading PN treatment at each order in spin, but kept the dynamics unrestricted. In the following we assume that the spin degrees of freedom are fixed, i.e., the spin vectors are independent of time, $a_{1,2} = 0$, and aligned with the orbital angular momentum of the system: $a_{1,2} \propto L^i$; hence, the motion is confined to the plane orthogonal to $L^i$. For later convenience, we define the unit vector $\ell^i$, such that $L^i \equiv |L|\ell^i$. Varying this action with respect to the worldline $z_1^i$, the classical EoM of the system are\footnote{The angular velocity tensor $\Omega^{\mu\nu} = \epsilon^{\mu} \cdot D\epsilon^{\nu}/d\lambda$ is defined by means of the body fixed frame $\epsilon^{\mu}_A(\lambda)$ along the worldline. The corresponding angular velocity vector is then given by $\Omega^i = \epsilon^i_{jk} \Omega^{jk}/2$. See, for instance, Ref. [93] for details.} [93, 94]

$$\dot{v}_1^i = \left( \partial^i - \epsilon_{ijk} a_1^j v^k \partial^j \right) \cosh(a_+ \times \partial) \frac{m_2}{r}$$

$$+ 2 \left( v_j \partial^j - \delta_j^i v^k \partial_k \right) \sinh(a_+ \times \partial)^i \frac{m_2}{r} + O(v^2).$$

A geometric approach using oblate spheroidal coordinates [93, 98, 99] or an algebraic approach, exploiting properties of the Legendre polynomials [94], under the assumption that the motion takes place in the plane orthogonal to the spin vectors, can be used to resum the series of differential operators in (2.5).

In order to present the contribution of the conservative sector needed for the radiative dynamics, we specialize to the center of mass frame for the rest of this section. The transformation into the center of mass variables $r^i$ based on (2.4) (and using the total mass $M = m_1 + m_2$), is corrected by the presence of the spins only at sub-leading orders in velocities:

$$z_1^i = \frac{m_2}{M} r^i - b^i, \quad z_2^i = -\frac{m_1}{M} r^i - b^i, \quad b^i := \frac{1}{M} \epsilon_{ijk} (v_1^j S_1^k + v_2^j S_2^k).$$

In this center of mass frame, the EoM are readily solved for quasi-circular motion. In that scenario, the separation $r^i$ is related to its acceleration $\ddot{r}^i$ by $r^i = -\ddot{r}^i/\omega^2$, where $\omega$ is the system’s orbital frequency. This ansatz picks out the quasi-circular orbits allowed by the BBH EoM (2.5) and is equivalent to finding a relation between the frequency $x = (M\omega)^{2/3}$,
the BHs spins $a_{1,2}^i$, and the separation of the binary $r$. This relation, at the leading PN order at each order in the BHs’ spins, is given by [94]

$$r(x) = \sqrt{\frac{M^2}{x^2} + \frac{\bar{a}_1^2}{3}} \left( 1 - \frac{x^{3/2} M}{M^2 + x^2 \bar{a}_2^2} \right),$$

where $\bar{\sigma}^* = (m_2 \bar{a}_1 + m_1 \bar{a}_2)/M$ and we defined $\bar{a}_{1,2} = a_{1,2}^i \ell_i$. It should be emphasized that the even-in-spin part of (2.7) contains only $O(v^0)$ information, while the odd-in-spin pieces are non-zero only at first sub-leading order in velocities, at $O(v^1)$. This solution can then be used to compute gauge invariant quantities of the conservative sector, such as the total binding energy and angular momentum [94].

2.2 Linearized metric perturbations at null infinity

With the conservative results in hand, in this subsection, we compute the gravitational waves from the BBH system at future null infinity. In sec. 2.2.1 we briefly review the general approach of mapping the source’s multipole moments into the radiation field, while in sec. 2.2.2 we derive the TT part of the linear metric perturbations (the gravitational waves) at null infinity utilizing this mapping.

2.2.1 General approach

A natural choice of gauge invariant quantity capturing the radiative dynamics at null infinity is the Newman-Penrose Weyl scalar $\Psi_4$. This contains both polarization states, $h_+$ and $h_\times$, of the emitted waves, which are the observables measured by gravitational wave detectors. Upon choosing a suitable null tetrad, the TT part of the gravitational field, $h_{\mu\nu}^{TT}$, can be related to $\Psi_4$:

$$\Psi_4 \sim \tilde{h}_+ - i\tilde{h}_\times = \bar{m}^\alpha \tilde{m}^\beta \tilde{h}_{\mu\nu}^{TT}.$$  (2.8)

The complex conjugate pair $\{m^\alpha, \bar{m}^\alpha\}$ is typically defined with respect to the flat spherically symmetric angular coordinate directions $m = (\Theta + i\Phi)/\sqrt{2}$. With this choice in place, we restrict our attention to the spatial components $h_{ij}^{TT}$, as these contain the full information of $\Psi_4$, i.e., the radiative, non-stationary, degrees of freedom\(^5\).

In the previous section, we summarized the leading PN conservative dynamics of a spinning BBH to all orders in their spins. Given this, the well-established multipolar post-Minkowskian formalism [3, 71–74] is ideally suited to determine the time-dependent metric perturbations at null infinity. Within this framework, the stress energy distribution of the source, $T_{\mu\nu}^{source}$, is mapped into a set of mass and current symmetric and trace free (STF) source multipole moments $I_{i_1...i_\ell}(t)$ and $J_{i_1...i_\ell}(t)$. We denote $\langle i_1...i_\ell \rangle$ as the STF projections of the indices $i_1...i_\ell$. Then the STF multipole moments evaluated at the

\(^5\)As we will see below, this choice of purely spatial $m^\alpha$ is equivalent to choosing a gauge, in which the graviton polarization tensor is also purely spatial.
retarded time $T_R = t - R$ are defined by [3]

$$I_{i_1 \cdots i_{\ell}} = \int d\mu \left( \delta_{i\ell}x_{(i_1 \cdots i_{\ell})} \Sigma - f_1,_{\ell} \delta_{i\ell+1}x_{(i_1 \cdots i_{\ell+1})} \Sigma^j + f_2,_{\ell} \delta_{i\ell+2}x_{(i_1 \cdots i_{\ell+2})} \Sigma^{ij} \right) (x, T_R + z r),$$

$$J_{i_1 \cdots i_{\ell}} = \int d\mu \varepsilon_{ab(i_\ell} \left( \delta_{b\ell}x_{i_1 \cdots i_{\ell+1}} a^{\Sigma b} - g_1,_{\ell} \delta_{i\ell+1}x_{i_1 \cdots i_{\ell+1}} c^{\Sigma b c} \right) (x, T_R + z r),$$

(2.9)

where $x_{i_1 \cdots i_{\ell}} = x_i \cdots x_i$,

$$f_1,_{\ell} = \frac{4(2\ell + 1)}{(\ell + 1)(2\ell + 3)}, \quad f_2,_{\ell} = \frac{2(2\ell + 1)}{(\ell + 1)(\ell + 2)(2\ell + 5)}, \quad g_1,_{\ell} = \frac{2\ell + 1}{(\ell + 2)(2\ell + 3)},$$

(2.10)

and the integration measure $\int d\mu = FP \int d^3 x \int_1^{\infty} dz$. The source energy-momentum distribution enters in $\Sigma$, via (valid only at leading PN orders)$^6$

$$\Sigma = T^{00} + T^{ij} \delta_{ij}, \quad \Sigma^i = T^{0i}, \quad \Sigma^{ij} = T^{ij}.$$ (2.11)

The source' finite size retardation effects are contained in the $z$-integral with $\delta_{i\ell} = \delta_{i\ell}(z)$ in (2.9), which are given explicitly in eq. (120) of Ref. [3]. At the orders considered in this work, at the leading PN orders, finite size-retardation effects vanish and the $z$-integral trivializes: $\int_1^{\infty} dz \, \delta_{i\ell}(z) f(x, T_R + z r) = f(x, T_R) + O(v^2)$. We discuss in §3.1, how a similar structure as in (2.9) appears in the scattering amplitudes approach, as well as what precisely encapsulates the “finite size” retardation effects in that context. The lowest order moments $I_i$, $\bar{I}_i$, and $\bar{J}_i$ are constants of motion representing the total conserved energy, center of mass position, and total angular momentum, respectively. Only for $\ell \geq 2$, do the multipoles contribute non-trivially.

A matching scheme enables to directly relate these functionals for the source’s stress-energy distribution, to the radiation field at null infinity (at 1PM order)$^7$ [3]

$$h_{ij} = -4 \sum_{\ell = 2}^{\infty} (-1)^{\ell} \left[ \partial_{i_1 \cdots i_{\ell-2}} \bar{T}_{ij}^{i_{1 \cdots \ell-2} R^{-1}} + \frac{2\ell}{\ell + 1} \partial_{a_{i_1 \cdots i_{\ell-2}}} \varepsilon^{ab} (i \bar{J}^a)_b^{i_{1 \cdots \ell-2} R^{-1}} \right].$$ (2.12)

Here $\partial_a R^{-1} = -N_a / R^2$ is to be understood as the derivative in the background Minkowski spacetime, where $N_a$ is radially outwards pointing from the source to spatial infinity, with $N_a N^a = 1$. To solely focus on the radiation at null infinity, we work to leading order in the expansion in $R^{-1}$. Therefore, the spatial derivatives in (2.12) act purely on the source multipole moments, and there, can be traded for time derivatives: $\partial_a f(t - R) = -\dot{f} N_a$.

Similarly, the total instantaneous gravitational wave energy flux $\mathcal{F}$ can be derived directly from the source multipole moments [3].

2.2.2 Gravitational radiation from spinning binary black hole

At the 1PM level, non-linear effects vanish such that the energy-momentum of the BBH is simply the superposition of two linearized Kerr BHs' energy momentum distributions

---

6At sub-leading PN orders, the stress energy of the emitted gravitational waves contributes to $\Sigma$.
7Beyond linear theory, corrections to these multipole moments are necessary [3].
\[ T^\text{source}_{\mu\nu} = T^K_{\text{Kerr},1} + T^K_{\text{Kerr},2} \] This superposition holds in the conservative sector, while the radiative dynamics are derived directly from derivatives acting on \( T^\text{source}_{\mu\nu} \) in the manner described in the previous section. From the scattering amplitudes perspective, this superposition is reflected in the \textit{only} two channel factorization of the classical 5-pt amplitude, into the product of a 3-pt amplitude and the gravitational Compton amplitude, as we will see in §3.2.

\textbf{Leading order in velocities} – As the radiative quantities \( h^{TT}_{ij} \) and \( F \) depend on time derivatives of the source multipole moments, we focus on time-dependent terms after fixing the angular momentum dynamics. For the case of the above spinning BBH with aligned spins, at the leading PN order, we expand the source \( T^\text{source}_{\mu\nu} \) analogously to (2.2). Given this, the resulting leading-in-velocity contributions to the source multipole moments, utilizing (2.9), are \[ I^{(0)}_{ij} = m_1 z^1_{1z} \langle ij \rangle_{1z} + (1 \leftrightarrow 2), \]
\[ J^{(0)}_{ij} = 3/2 S^1_{ij} \langle ij \rangle_{1z} + (1 \leftrightarrow 2), \] (2.13) where \((0)\) indicates the order in velocities. It should be stressed that these are all multipoles needed for the gravitational waveform to all orders in the BHs’ spins, at leading order in velocity [94]. From the amplitudes perspective, this will be reflected in the need for only the scalar and linear-in-spin scattering amplitudes at the leading orders in velocities. While all higher-order spin terms in the source multipole moments vanish identically, spin contributions to the waveform at arbitrary order in the spin expansion could enter through the solution to the EoM (2.7). We see below that this solution to the classical EoM (2.5) introduces non-zero contributions at arbitrary orders in the BHs’ spins for quasi-circular orbits.

Given (2.13), the metric perturbation at null infinity, for general orbits at zeroth order in velocities, assuming aligned spins, is
\[ h^{(0)ij}_{S \infty}(T_R, R, N, z_1, z_2) = 2m_1 R \left\{ \frac{d^2}{dt^2} \left[ z^1_{1z} \right] + \varepsilon_{pq}^{(i} \left( a^j_{1z} \dot{v}^p_{1z} + \dot{v}^j_{1z} a^p_{1z} \right) N^q \right\}_{t=T_R} + (1 \leftrightarrow 2), \]
(2.14) i.e. the Einstein Quadrupole formula with spinning corrections for a binary system. We specialize to quasi-circular orbits by introducing the orthogonal unit vectors
\[ n^i = r^i/r = (\cos \omega t, \sin \omega t, 0)^i, \]
\[ \lambda^i = v^i/v = (-\sin \omega t, \cos \omega t, 0)^i, \] (2.15) in the center of mass frame that rotate with frequency \( \omega \) in the orbital plane. The spin vectors \( a^1, 2 \propto \ell^i \) are aligned orthogonal to the orbital plane, \( n^i \lambda^j \varepsilon_{ij}^k = \ell^k \), such that \( \ell^i = (0, 0, 1)^i \). Furthermore, the TT projector
\[ \Pi^{ij}_{kl} = P^i_k P^j_l - \frac{1}{2} P^{ij} P_{kl} \] (2.16) is defined relative to \( N_a \), where \( P_{ij} = \delta_{ij} - N_i N_j \). Utilizing (2.6), together with the solution (2.7) to the EoM, as well as (2.13), the gravitational waves emitted by the spinning BBH to all orders in the BHs’ spins is conveniently written as
\[ h^{TT}_{ij}(T_R) = \frac{2\mu}{R} \Pi_{ij}^{ab} \hat{h}_{ab} \bigg|_{t=T_R}, \]
(2.17)
where at leading order in velocities, we have $\hat{h}_{ab}^{(0),I2} = \hat{h}_{ab}^{(0),J2}$, with

\begin{equation}
\hat{h}_{ab}^{(0),I2} = -2x \left( 1 + \frac{\vec{a}^2 x^2}{M^2} \right) (n_an_b - \lambda_a \lambda_b)
\end{equation}

\begin{equation}
\hat{h}_{ab}^{(0),J2} = -\frac{x^2 \vec{a}_r}{M} \sqrt{1 + \frac{\vec{a}^2 x^2}{M^2}}, \varepsilon_{kld}(\ell_b n^k + n_b \ell^k) N^l.
\end{equation}

Notice that here, the odd-in-spin contribution, $\hat{h}_{ab}^{(0),J2}$, is a series that has non-zero coefficients at arbitrary orders in spin, arising from the odd part of the solution (2.7), while, on the other hand, the even-in-spin part, $\hat{h}_{ab}^{(0),I2}$, provides coefficients that vanish for $O(a^{\ell \geq 3})$. This is analogous to the cancellations observed in the conservative and radiative sectors reported in Ref. [94]. We find agreement with the results reported in Refs. [105–107] to the respective finite order in spin. To check for consistency to all orders in spin, the gravitational wave modes are extracted from the spatial part of the metric perturbations, in (2.18), by projecting onto a suitably defined basis of spin-weighted spherical harmonics, $-\frac{1}{2} Y_{\ell m}(\Theta, \Phi)$. Explicitly, the gravitational wave modes $h_{\ell m}$ are defined to be $h_{\ell m} = \int d\Omega -\frac{1}{2} Y_{\ell m}(\Theta, \Phi) \bar{m}^a \bar{m}^\beta h^{TT}_{\mu\nu}$. These modes, obtained from (2.18) in conjunction with the above defined polarization tensor $\bar{m}^a \bar{m}^\beta$, agree with the results in Ref. [94] to all orders in the BHs’ spins at leading order in their velocities.

Sub-leading order in velocities – The sub-leading corrections to the above radiation field are obtained in much the same way. The additional contributions to the source multipole moments, beyond the leading pieces (2.13), at sub-leading orders in velocities are [92, 94, 105]

\begin{equation}
\mathcal{I}^{ij}_{(1)} = 4 \left( 2v_1^a S_1^b \varepsilon_{ab} (i \bar{z}^j) - z_1^a S_1^b \varepsilon_{ab} (i \bar{\nu}^j) \right) + (1 \leftrightarrow 2),
\end{equation}

\begin{equation}
\mathcal{I}^{ijk}_{(1)} = m_1 z_1^{(ijk)} - \frac{3}{m_1} S_1^{(ij)k} + (1 \leftrightarrow 2),
\end{equation}

\begin{equation}
\mathcal{J}^{ij}_{(1)} = m_1 z_1^{a} v_1^b \varepsilon_{ab} (i \bar{z}^j) + \frac{1}{m_1} v_1^a S_1^b \varepsilon_{ab} (i \bar{\nu}^j) + (1 \leftrightarrow 2),
\end{equation}

\begin{equation}
\mathcal{J}^{ijk}_{(1)} = 2 S_1^{(ij)k} + (1 \leftrightarrow 2).
\end{equation}

Also here, we focused only on those pieces that are time-dependent, i.e., that will contribute non-vanishing terms in $\hat{h}_{ij}^{(1)TT}$. Additionally, as pointed out above, these are all necessary contributions for the full all orders-in-spin information at sub-leading orders in velocities (at leading PN order) [94]. Using this, together with the mapping (2.12), the decomposition (2.17), and $\hat{h}_{ab}^{(1)} = \hat{h}_{ab}^{(1),I2} + \hat{h}_{ab}^{(1),J2} + \hat{h}_{ab}^{(1),I3} + \hat{h}_{ab}^{(1),J3}$, the sub-leading contribution $\hat{h}_{ij}^{(1)TT}$ to
all orders in spin from a spinning binary black hole on quasi-circular orbits are

\[ \hat{h}_{ab}^{(1),12} = \frac{4x^{5/2}}{3M^3} \left( 2\bar{\alpha}_+ M^2 + (M^2 - 2x^2) \bar{\sigma}^* \right) \left( n_a n_b - \lambda_a \lambda_b \right), \]
\[ \hat{h}_{ab}^{(1),12} = \frac{x^{5/2}}{3M^4 r_e} \left[ 2r_e^4 x^2 \delta m + \bar{a}_- M \left( 2\bar{a}_+ (M^2 - r_e^2 x^2) + 3r_e^2 x^2 \bar{\sigma} + M^2 \bar{\sigma}^* \right) \right] \times \varepsilon_{p\ell q(a)N^q} \left( n^p \ell_b + n_b \ell^p \right), \]
\[ \hat{h}_{ab}^{(1),13} = \frac{r_e x^{9/2}}{15M^2} \left[ 15\bar{a}_+ \bar{\alpha} - 2x^2 \delta m \left( 30 \lambda_a \lambda_b \lambda_k - 105 n_\alpha (n_a \lambda_b \lambda_k) \right) \right] N^k, \]
\[ \hat{h}_{ab}^{(1),13} = -\frac{48r_e^2 x^{9/2} \bar{\sigma}^*}{6M^3} \varepsilon_{pq(a)\bar{\delta}b} \left( n^{(k} \lambda^p \ell^{q)} N^q N_e. \right) \]

Here \( r_e = \left( \bar{a}_e^2 + M^2 / x^2 \right)^{1/2} \), which is just the leading-in-velocities (even-in-spin) solution to the classical EoM (2.7) for quasi-circular orbits. We check the gravitational wave modes obtained from (2.20) with those presented in Ref. [94] and find agreement to all orders in spin. Additionally, we compute the gauge invariant gravitational wave energy flux with the above result together with the leading-in-velocities radiation field and find agreement with results reported in [92, 94] (see also a detailed discussion in sec. 3.4 below). Finally, in order to compare to the scalar amplitude at first sub-leading orders in the BHs’ velocities in §3.3.4, we also present the radiation field of a non-spinning BBH system on general orbits, to sub-leading order in velocities:

\[ h_{ab}^{(1),ij} = \frac{2m_1}{3R} \Pi^{ij} \left[ 4\varepsilon_{pq} \left( \bar{\sigma}^* \right) \right] N^q + N_k \delta^{\beta}_k \left( \bar{\sigma}^* \right) + (1 \leftrightarrow 2). \text{(2.21)} \]

### 3 Scattering Amplitudes derivation

In the previous sections, we obtained the form of the gravitational waves emitted from a spinning BBH on general closed orbits with aligned spins, to leading order in the BHs’ velocities (2.14) [and on quasi-circular orbits given in (2.18)], whereas at sub-leading order in \( v \), and for quasi-circular orbits, we derived (2.20), at each order (and to all orders) in the BHs’ spins. In the following, we show that these results follow directly from the classical limit of a 5-pt scattering amplitude. More precisely, at leading order in velocity there is a one-to-one correspondence between the source’s mass and current multipole moments (2.13), and the scalar and linear-in-spin contribution to the scattering amplitude, respectively. This correspondence allow us to derive the linear in spin, general orbit result for the radiated gravitational field (2.14), from an amplitudes perspective. At quadratic order in the BHs’ spins, and for quasi-circular orbits, we demonstrate that the contribution from the quadratic in spin amplitude is canceled by the contribution of the scalar amplitude in conjunction with the \( O(S^2) \)-piece of the EoM (2.5). This leaves only the quadrupole field, (3.22), supplemented with the solution to the EoM (2.7), to enter at quadratic order in spin. Although we explicitly demonstrate the cancellation for quasi-circular orbits and up to quadratic order in spin only, we expect this theme to continue to hold for more complicated bound orbits, as well as to higher spin orders in the 5-pt scattering amplitude, as suggested by the classical multipole moments (2.13). At sub-leading orders
in the BHs’ velocities the situation becomes more complicated; there, we demonstrate the matching of the amplitudes to the classical computation in the spin-less limit for quasi-circular orbits, and briefly comment on extensions to higher orders in spin. In this section, we use the mostly minus signature convention for the flat metric \( \eta_{\mu\nu} = \text{diag}(1, -1, -1, -1) \).

\[ (3.1) \]

**Figure 1.** Bremsstrahlung (outgoing graviton) emitted during the scattering of two spinning massive bodies (massive spin-\( s \) quantum particles) exchanging gravitational/electromagnetic waves.

### 3.1 General approach

To compute the radiated field at future null infinity from the BBH system we follow the approach used by Goldberger and Ridgway in [13] to derive the Quadrupole formula, and extend it to include relativistic and spin effects. This approach is based on the classical EoM for the orbiting objects in combination with the corresponding 5-pt (spinning) scattering amplitude (see Figure 1). It is valid for BBHs whose components have Schwarzschild radii \( r_{1,2} = 2m_{1,2} \) much smaller than their spatial separation \( r \), i.e., \( r_{1,2} \ll r \), while the radiation field wavelength is much bigger than the size of the individual components \( \lambda \gg m_{1,2} \), as well as the size of the system \( \lambda \gg r_8 \). Therefore, we expect our results to be situated in the PN regime of the binary inspiral\(^9\).

Let us start by noting that in the limit in which \( R \to \infty \), where \( R \) is the distance from the source to the observer (i.e., the radial coordinate in Bondi-Sachs gauge) as defined above, the time domain waveform at retarded time \( T_R \), has the asymptotic form [109]

\[
h^{ij}_{TT}(T_R, R, \mathbf{N}, z_1, z_2) = \frac{\kappa}{16\pi R} \Pi^{ij}_{ab} \int d\tilde{\omega} e^{-i\tilde{\omega} T_R} T^{ab}(\tilde{\omega}, \mathbf{N}, z_1, z_2). \tag{3.1}
\]

Here \( \kappa^2 = 32\pi \) (recall we set \( G = 1 \)), \( \tilde{\omega} \) is the frequency of the radiated wave with four momentum \( k^\mu = \tilde{\omega} \mathcal{N}^\mu = \tilde{\omega}(1, \mathbf{N})^\mu \), and \( \Pi^{ij}_{ab} \) is the TT-projector defined in (2.16). As above, the locations of the binary’s components are denoted by \( z_{1,2} \). Analogous to the

---

\(^9\)In the long distance separation regime, radiation reaction effects can be neglected, since they become important only when the separation of the two bodies is comparable to the system’s gravitational radius [108] eq. 36.11.

\(^8\)We stress that even though we concentrate mostly in the computation of gravitational waveform, an analogous derivation follows for electromagnetic radiation, as already pointed out in [13].
previous section, we focus only on the spatial components of \( h^{\mu\nu} \), which contain all the radiative degrees of freedom. In what follows we also simplify the notation for the source \( T^{ab}(\tilde{\omega}, N, z_1, z_2) \rightarrow T^{ab}(k, z_1, z_2) \), where it is understood that \( k^\mu \) has implicit the dependence in both, \( \tilde{\omega} \) and \( N \).

The source \( T^{ab}(k, z_1, z_2) \), is related directly to the 5-pt scattering amplitude in Figure 1; therefore, in order to focus on the spatial components, it is sufficient to work in a gauge, in which the graviton polarization tensor \( e^{\mu\nu} = e^{\mu}e^{\nu} \), is the tensor product of two purely spatial polarization vectors \( e^{\nu} \). From the classical perspective, this choice of gauge is analogous to the conjugate pair \( \{m^{\alpha}, \bar{m}^{\alpha}\} \) (defined in §2.2.1) to be purely spatial. Notice, however, the radiation field computed from a 5-pt scattering amplitude, and the corresponding field computed classically in the previous section, can in general differ by a gauge transformation. As shown below, this is directly related to a freedom in choice of an integration by parts (IBP) prescription in (3.1).

We proceed by writing the explicit form of the source \( T^{ij}(k, z_1, z_2) \) in terms of the classical 5-pt scattering amplitude. In the classical computation, \( T^{ij} \) corresponds to the source entering on the right hand side of field equations, at a given order in perturbation theory. To leading order, for scalar particles, it was shown in [13] that the source can be rearranged in such a way, so that the scalar 5-pt amplitude can be identified as the main kinematic object entering the graviton phase space integration, as well as the integration over the particles proper times (which account for the particles history). In this paper we propose that formula to also hold for spinning particles. That is,

\[
T^{ij}(k, z_1, z_2) = \frac{i}{m_1 m_2} \int d\tau_1 d\tau_2 d^4q_1 d^4q_2 \delta^4(k - q_1 - q_2) e^{iq_1::z_1} e^{iq_2::z_2}(\Lambda^{ij}_5(q_1, q_2, k)).
\]

(3.2)

Here \( (\Lambda^{ij}_5) \) is the classical 5-pt amplitude \(^{10}\). Conventions for the particles’ momenta and the spins are shown in Figure 1, with the condition for momentum conservation \( q_1 + q_2 = k \).

We have used the notation \( d^4 q_i = \frac{d^3q_i}{2\pi^3} \), and similarly for the momentum-conserving delta function \( \delta^4(p) = (2\pi)^4 \delta^4(p) \). The position vectors are \( z^I_A = (\tau_A, z_A)^\mu \), with \( A = 1, 2 \), as described in §2.1.1, where the proper times \( \tau_A \), parametrize the BHs’ trajectories. Here the

\(^{10}\)To motivate this formula, although this is by no means a formal derivation, as already observed in [13] for the tree-level amplitude, we can take the expression for the radiation kernel eq. (4.42) in the KMOC original work [50]

\[
\mathcal{J} = \lim_{\hbar \to 0} \frac{1}{m_1 m_2} \left\langle \prod_{i=1}^{2} \left[ d^4 q_i \delta(v_i, q_i - q_i'/(2m_i))e^{ib_i, q_i} \right] \delta^4(k - q_1 - q_2) \Lambda_5 \right\rangle,
\]

(3.3)

and use the integral representation for the on-shell delta functions \( \delta(x) \sim \int dy e^{ixy} \). Identifying the asymptotic trajectories for the particles \( \tau_i(\tau) = b_i^+ + e_i^+ \tau_i \), plus a quantum correction \( z_0^I(\tau_i) = -\frac{\hbar}{2m_i} \tau_i \), and upon restoring the \( \hbar \)-counting in the exponential, the radiation kernel can be rewritten as

\[
\mathcal{J} = \lim_{\hbar \to 0} \frac{1}{m_1 m_2} \left\langle \prod_{i=1}^{2} \left[ d\tau_i d^4 q_i e^{ib_i, (\gamma_i + \hbar q_i(\tau_i))} \right] \delta^4(k - q_1 - q_2) \Lambda_5 \right\rangle.
\]

(3.4)

In the classical limit, and to leading order in perturbation theory, we can simply drop quantum correction to the particles trajectories \( z_0^I(\tau_i) \), and recover the formula (3.2) upon promoting \( z_i(\tau) \) to be valid for generic time dependent orbits.
product of the exponential functions, $\prod A e^{i q_A z_A}$, represents the two-particles initial state where each particle is taken to be in a plane-wave state. This is nothing but the Born approximation in Quantum Mechanics (See also [70]).

We have stripped away the graviton polarization tensor in (3.2), assuming there exist the aforementioned gauge fixing for which the graviton polarization tensor is purely spatial. We can further rewrite the source using the symmetric variable $q = (q_1 - q_2)/2$, as well as exploiting the momentum conserving delta function to remove one of the $q_i$-integrals. The result reduces to

$$T^{i j}(k, z_1, z_2) = \frac{i}{m_1 m_2} \int d\tau_1 d\tau_2 d^4 q e^{i \tilde{z} \cdot \tilde{z}} e^{-i q \cdot z} \langle M^{i j}_5(q, k) \rangle,$$  

(3.5)

where $\tilde{z} = (z_1 + z_2)/2$ and $z_{BA} = z_B - z_A$. Since we are interested in the bound-orbit problem, we take the slow-motion limit. Therefore, we can write the momenta of the BHs moving on closed orbits in the form $p_{1,2}^i = m_{1,2} v_{1,2}^i$. As noted above, we choose the frame in which $v_{1,2}^i = (1, v_{1,2})^\mu + O(v_{1,2}^2)$, where $v_{1,2} = dz_{1,2}/d\tau$, i.e. with the proper times $\tau_{1,2}$ replaced by the coordinate time (see details below). On the other hand, in the closed orbits scenario the typical frequency of the orbit $\omega$, scales with $v$ as $\omega \sim v/r$, where $\omega = v/r$ for quasi-circular orbits (see also (2.15)). In this bound-orbits case the integration in $q$ is restricted to the potential region (technically, as an expansion in powers of $q_0^0/|q|$), where the internal graviton momentum has the scaling $q \sim (v/r, 1/r)$, while the radiated graviton momentum scaling is $k \sim (v/r, v/r) = \bar{\omega}(1, \mathbf{N})$ (with $\bar{\omega} \sim \omega$). Integration in the potential region ensures that from the retarded limit, retardation effects only become important at order $O(v^2)$, which we do not consider here. At subleading orders in velocities, the amplitude $(M^{i j}_5(q, k))$ has no explicit dependence on $q_0$. This takes care of the $q_0$-integration in (3.5), which results in the delta function $\delta(t_2 - t_1)$; this can be used to trivialize one of the time integrals\textsuperscript{11}. With all these simplifications in hand, the source (3.5) becomes

$$T^{(0)}_{i j}(k, z_1, z_2) = \frac{i}{m_1 m_2} \int dt d^3 q e^{i \bar{\omega} t - i q \cdot z} \langle M_{5,S^0}^{(0) ij}(q, \bar{\omega}) + M_{5,S^1}^{(0) ij}(q, \bar{\omega}) + M_{5,S^2}^{(0) ij}(q, \bar{\omega}) + \cdots \rangle,$$  

(3.7)

where the amplitude was written in a spin-multipole decomposition. The superscript $(0)$ indicates that we restrict these to the leading-in-$v$ contribution to the scattering amplitude (See §3.3.4 for the computation at the first sub-leading order in velocities contribution, for spinless BHs).

**3.2 Scattering amplitude and double copy**

With the general formalism to compute the radiated field for the BBH system outlined above, we are left to provide the classical limit of the 5-pt amplitude to be used in the waveform formula (3.1). The amplitude takes the general form [51]

\textsuperscript{11}As a connection with the classical computation, the source multipole moments [given in (2.13)] contain the finite size and retardation effects of the binary, though, at leading and sub-leading orders in velocities, these effects vanish (see e.g., [3]), which is equivalent to the replacement $\tau_{1,2} \to t$ above.
\[ \langle M_5^h \rangle = \frac{-i}{(q \cdot k)^{h-1}} \left[ \frac{n_h^{(a)}}{(q^2 - q \cdot k)(p_1 \cdot k)^2} + \frac{n_h^{(b)}}{(q^2 + q \cdot k)(p_2 \cdot k)^2} \right], \tag{3.8} \]

where \( n_h^{(i)} \) are kinematic numerators given below. Here we have also included the photon case \( h = 1 \), in order to make contact with existing literature, as well as providing new results at \( \mathcal{O}(S^2) \). This formula follows from the factorization of the 5-pt amplitude (Figure 1) into the product of a Compton- and a 3-pt amplitude. Then, each kinematic numerator is computed from the residue of the 5-pt amplitude, at the corresponding pole. Schematically, we have

\[ \langle M_5^h \rangle = \begin{array}{c}
\includegraphics[width=0.5\textwidth]{factorization_diagram.png}
\end{array} + (1 \leftrightarrow 2). \tag{3.9} \]

From this factorization, it is clear that the spurious pole \( q \cdot k \) appearing in (3.8) for the gravitational case, \( h = 2 \), arises from the \( t \)-channel of the gravitational Compton amplitude, and cancels out in the final result. It was also shown extensively in [51] that the gravitational numerators in (3.8) can be computed from a double copy of two photon numerators. That double copy is nothing but the result of the KLT double copy of 3- and 4-pt amplitudes entering in (3.9), which can be written symbolically as \( A_n^{(s, gr)} = K_n A_n^{(0, em)} \times A_n^{(s, em)} \) for \( n = 3, 4 \); i.e., they factorize into the product of the scalar and the spin-\( s \) electromagnetic amplitudes [36]. Here we make use of this factorization to write out the explicit form of the numerators for both, photon and graviton radiation.

### 3.2.1 Electromagnetic 5-pt amplitude

We now provide the explicit example for the 5-pt amplitude (3.8), in the electromagnetic case. We start by introducing the notation for the contractions \( F \cdot J_{s,A} = F_{\mu \nu} J^{\mu \nu}_{s,A} \), where \( F_{\mu \nu} \) is the electromagnetic field strength tensor, and \( J^{\mu}_{s,A} \) are the spin-\( s \) generators for particle \( A \), in Maxwell theory. Furthermore, we also define the variables

\[ R_{s,i}^{\mu \nu} = p_i^{[\mu} (2 \eta_i q - k)^{\nu]}, \quad \hat{R}_{s,i}^{\mu \nu} = 2 (2 \eta_i q - k)^{[\mu} J_{s,i}^{\nu]} (2 \eta_i q - k)^{\alpha}, \tag{3.10} \]

with \( \eta_1 = -1 \) and \( \eta_2 = 1 \). With this notation in hand, the scalar numerators for photon radiation read explicitly

\[ n_{0,ph}^{(a)} = 4e^3 p_1 \cdot R_2 \cdot F \cdot p_1, \quad n_{0,ph}^{(b)} = 4e^3 p_2 \cdot R_1 \cdot F \cdot p_2, \tag{3.11} \]

where \( e \) is the electron charge. This is nothing but the gluing of the numerator of the spinless electromagnetic Compton amplitude, \( A_4 \sim p_i \cdot F_i \cdot F_j \cdot p_i \), [111], and the scalar

\[ \text{In [44] it was also shown that for gravity, this classical formula follows directly from the classical limit of the standard BCJ double copy [110], where superclassical contribution to the amplitude can be gauged away by the use of a Generalized Gauge Transformation of the BCJ numerators.} \]

\[ \text{Here } p_i \text{ is the incoming passive momentum, and } F_i \text{ and } F_j \text{ are the field strength tensors for the incoming and outgoing photons, respectively.} \]
3-pt amplitude \( A_3 \sim p_s^4 \), through the photon propagator \( \eta_{\mu
u} \). The triple product notation here corresponds to the ordered contraction of the Lorentz indices of all components, \( p_i F_I F_j p_i = p_i \mu F_I^{\mu
u} F_{j \nu} \cdot \alpha p_i \alpha \). Furthermore, the linear-in-spin numerators are

\[
\begin{align*}
n_{1,ph}^{(a)} & = n_{0,ph}^{(a)} - 2e^2 \left[ p_1 \cdot R_2 k F_s J_{s,1} - R_{1q} R_2 \cdot J_{s,1} + p_1 \cdot k [F, R_2] J_{s,1} - p_1 F \cdot \tilde{R}_2 p_1 \right], \\
n_{1,ph}^{(b)} & = n_{0,ph}^{(b)} - 2e^2 \left[ p_2 \cdot R_1 k F_s J_{s,2} - R_{2q} R_1 \cdot J_{s,2} + p_2 \cdot k [F, R_1] J_{s,2} - p_2 F \cdot \tilde{R}_1 p_2 \right],
\end{align*}
\] (3.12)

where we introduced the commutator notation \([F, R_2] J_{s,i} = (F^\mu_2 R_2^\alpha - R_2^\alpha F^{\mu\alpha})(J_{s,1})_{\mu\alpha}\).

These numerators follow analogously from the gluing of the electromagnetic spin-1/2, 3-pt and 4-pt amplitudes [51]. Using variables (3.10) to rewrite the numerators, trivializes the check for gauge invariance. Notice, on the other hand, the spin contribution in the \( \tilde{R}_i \) terms emerges purely from the linear-in-spin piece of the 3-pt amplitude, whereas the linear-in-spin Compton amplitude is responsible for the remaining terms. One can easily check that by replacing the numerators (3.11) and (3.12) in the general formula (3.8), we recover the classical photon radiation amplitude for the scattering of two colorless charges, with and without spin (compare [112] and [113], respectively). These numerators have the support of \( \delta(p_i (\eta q - k)) \), which imposes the on-shell condition for the outgoing massive particles in the classical limit\(^{14}\). Finally, the quadratic order in spin numerators are included in the ancillary Mathematica notebook for this paper. These, again, follow from the electromagnetic quadratic-in-spin 3-pt and 4-pt amplitude, with the latter also included in the ancillary file.

For simplicity, at this order we have restricted to the case in which only one particle has spin, while the other is scalar.

### 3.2.2 Gravitational 5-pt amplitude

Let us now provide the relevant amplitudes to be used in (3.1) – the gravitational amplitudes. We start with the scalar case, for which the gravitational numerators are

\[
\begin{align*}
n_{0,gr}^{(a)} & = \frac{\kappa^3}{4} \left[ (p_1 \cdot p_2 F_{1q} - p_1 k F_{p})^2 - \frac{m_2^2 m_1^2}{2} F_{1q}^2 \right], \\
n_{0,gr}^{(b)} & = -\frac{\kappa^3}{4} \left[ (p_1 \cdot p_2 F_{2q} + p_2 k F_p)^2 - \frac{m_2^2 m_1^2}{2} F_{2q}^2 \right],
\end{align*}
\] (3.13)

where we have used \( F_{1q} = \eta_i (p_i F q) \), and \( F_p = p_1 F p_2 \). Analogous to the electromagnetic numerators, this can also be obtained from the gluing of the scalar, 3-pt and 4-pt amplitudes through the graviton propagator. These numerators can be introduced in the general formula (3.8), to recover the result for the classical limit of the gravitational amplitude for scalar particles [44, 113, 114]. Next, the gravitational numerators to linear-order in spin

\(^{14}\)The classical limit is taken using the \( \hbar \)-rescaling of the massless momenta, and then taking the leading order for \( \hbar \to 0 \). We have to notice also that in numerators (3.12) and (3.14) below, we have removed the indices \( \{\alpha, \beta\} \) \( J_p^{\alpha i (\beta i)} \) that contract with the polarization vectors/tensors for the massive particles. In the classical setup, we interpret \( J_p^{\mu i (\alpha)} \) simply as the classical spin tensor \( S^{\mu \nu} \), which satisfies the spin supplementary condition \( p_\mu S^{\mu \nu} = 0 \).
can analogously be computed to get

\[ n^{(a)}_{\frac{3}{2}; \text{gr}} = \frac{\kappa^3}{8} \left\{ (p_1 \cdot p_2 F_{1q} - p_1 \cdot k F_p) \left[ (p_1 \cdot p_2 q \cdot k + p_1 \cdot k p_2 \cdot k) F \cdot J_{2s,1} - F_{1q} R_{2s} \cdot J_{2s,1} + p_1 \cdot k [F, R_2] \cdot J_{2s,1} \right] \\
+ \frac{m_2^2 F_{1q}}{2} \left[ F_{1q} (2q - k) \cdot J_{2s,1} p_1 - m_1^2 q \cdot k F \cdot J_{2s,1} + p_1 \cdot k (2q - k) \cdot F \cdot J_{2s,1} p_1 \right] \right\}, \]

\[ n^{(b)}_{\frac{3}{2}; \text{gr}} = -\frac{\kappa^3}{8} \left\{ (p_1 \cdot p_2 F_{2q} + p_2 \cdot k F_p) \left( F_{2q} (2q + k) \cdot J_{2s,1} p_2 - p_2 \cdot k p_2 \cdot F \cdot J_{2s,1} (2q + k) \right) \\
+ \frac{m_2^2 F_{2q}}{2} (2q + k) \cdot J_{2s,1} p_1 \right\}. \]

(3.14)

Here we point out that the generators \( J_{2s,1} \) act in the gravity theory rather than their electromagnetic counterpart. Similarly to the scalar case, these numerators can be placed in (3.8) to recover the corresponding gravitational amplitude. To obtain the full amplitude for both particles with spin, we utilize the symmetrization mappings

\[ m_1 \leftrightarrow m_2, \quad p_1 \leftrightarrow p_2, \quad q \rightarrow -q, \quad J_{2s,1} \rightarrow J_{2s,2}, \]

(3.15)

in the final formula. The resulting amplitude recovers the spinning amplitude in dilaton gravity computed in [112] for classical spinning sources, once the terms proportional to \( m_i \) in the numerators in (3.14), which arise from the graviton propagator, are removed.

Analogous to the electromagnetic case in §3.2.1, at the quadratic order in spin, for simplicity, we restrict ourselves to the scenario, where only one BH is spinning, \( S_2 \rightarrow 0 \).

We include the numerators as well as the gravitational Compton amplitude in the ancillary Mathematica notebook. We have checked that up to a contact term, which is irrelevant for the gravitational waveform, the quadratic-in-spin amplitude recovers the results in [61]\(^\text{15}\).

### 3.3 Computation of the radiated field

In the previous sections, we built up the 5-pt gravitational spinning scattering amplitude up to quadratic order in the BHs’ spins. With this, we can now return to (3.1) to successively construct the emitted classical gravitational radiation from the spinning BBH at increasing PN order. First, we compute the gravitational waveform to leading order in velocity up to quadratic order in the BHs’ spins, while turning to the computation of the waveform at sub-leading order in the BHs’ velocities in the spin-less limit in §3.3.4.

#### 3.3.1 Scalar waveform

The derivation of the Einstein quadrupole formula from scattering amplitudes was first done by Hari Dass and Soni in [70]; more recently, it was derived by Goldberger’s and Rigway’s classical double copy approach [13]. In the following, we re-derive the scalar term of the waveform in the Goldberger and Rigway setup, for completeness. This in turn, will outline the formalism used throughout the remaining sections to arrive at the corrections to the

\(^{15}\text{We would like to thank Gustav Mogull et al. for sharing their results with us before publication.}\)
These second term of this expression can be further integrated, since
\[\Delta \sum \text{ particle labels}, \]
As for the first term, this can be rewritten using
\[E\text{instein quadrupolar form:} \]
which in turn implies that the radiated field \((3.1)\) for a non-spinning BBH takes the familiar
\[\frac{\kappa^2}{32\pi} \sum_{A,B} m_A m_B \frac{z^a_{AB} z^a_{AB}}{r^3} = -\sum_A m_A \left( \frac{\dot{z}^b_A z^a_A + \dot{z}^a_A z^b_A}{2} + 2 \nu^a_A \nu^b_A \right). \]
derived from the scalar EoM. Putting these ingredients together into \((3.18)\), we find the scalar source to be
\[\frac{\kappa^2}{32\pi} \sum_{A,B} m_A m_B \frac{z^a_{AB} z^a_{AB}}{r^3} = \sum_A m_A \left( \frac{\dot{z}^b_A z^a_A + \dot{z}^a_A z^b_A}{2} + 2 \nu^a_A \nu^b_A \right). \]
Using the relation \(2\nu^a_A \nu^b_A = \frac{d^2}{dt^2} \left( z^a_A z^b_A \right) - \left( \frac{\dot{z}^a_A \dot{z}^b_A + \dot{z}^b_A \dot{z}^a_A}{2} \right)\), the above expression can be put into the more compact form
\[\frac{\kappa^2}{32\pi} \sum_{A,B} m_A m_B \frac{z^a_{AB} z^a_{AB}}{r^3} = -\sum_A m_A \left( \frac{\dot{z}^b_A z^a_A + \dot{z}^a_A z^b_A}{2} + 2 \nu^a_A \nu^b_A \right). \]
The sequence of Fourier transforms in the source (3.21) and (3.1) leads to the evaluation of the emitted gravitational radiation at retarded time $T_R$, therefore, recovering the classical result (2.14) in the no-spin-limit. As a quick remark, notice when restoring Newton’s constant $G$ the quadrupole radiation is linear in $G$, as opposed to gravitational Bremsstrahlung, which is quadratic [115–118]. This is of course just a feature of using the EoM to rewrite the source.

3.3.2 Linear-in-spin waveform

In the previous section, the main components of the derivation of the gravitational waveform from a compact binary system were outlined. In particular, we have seen that the classical EoM play an important role in recovering the quadrupole formula. Going beyond this, at linear order in the BHs’ spins, there are two contributions to the waveform. First, the scalar amplitude could be iterated with the linear-in-spin part of the classical EoM (2.5); this contribution, however, is sub-leading in velocity as made explicit in (2.5). Secondly, the linear-in-spin amplitude, in conjunction with the non-spinning part of the EoM gives rise to a leading in BHs’ velocities and linear-in-their spins contribution to the waveform. To determine the latter, we start from the linear-in-spin amplitude (3.14), where the leading in $v$ expression is given by

$$\langle M^{(0)}_{S,S_1}(q,\bar{\omega}) \rangle = -\frac{m_1m_2\kappa^3}{8} \varepsilon_{efk} \left( m_2S_1^k - m_1S_2^k \right) N[e \left( \delta[^a]a \delta^b c + \delta[^b]b \delta^a c \right) \frac{q^c}{q^2}. \quad (3.23)$$

Analogous to the scalar case, we can substitute this amplitude into (3.7) to get the linear-in-spin source $T^{(0)}_{S_1}$. After integrating over $q$, utilizing (A.3), this source simplifies to

$$T^{(0)}_{S_1}(k, z_1, z_2) = \frac{\kappa^3}{32\pi} \varepsilon_{efk} \left( m_2S_1^k - m_1S_2^k \right) N[e \left( \delta[^a]a \delta^b c + \delta[^b]b \delta^a c \right) \int dt e^{i\bar{\omega}t} \frac{\dot{\psi}^1}{r^3}. \quad (3.24)$$

Powers of $r$ in the denominator can be removed by using the scalar limit of the classical EoM (2.5). Then, analogous to the scalar computation, the linear-in-spin source is

$$T^{(0)}_{S_1}(k, z_1, z_2) = \kappa \varepsilon_{efk} S_1^k N[e \left( \delta[^a]a \delta^b c + \delta[^b]b \delta^a c \right) \int dt e^{i\bar{\omega}t} \dot{\psi}^1 + (1 \leftrightarrow 2). \quad (3.25)$$

Finally, the linear in spin corrections to the Einstein quadrupole formula, derived from the above amplitude, obtained from (3.25), together with (3.1), are

$$h^{(0)ij}_{TT, S_1}(T_R, R, N, z_1, z_2) = \frac{\kappa^2}{16\pi R} \Pi^{ij}_{ab} \varepsilon_{efk} \sum_A S_A^k \left[ N[e \left( \delta[^a]a \delta^b c + \delta[^b]b \delta^a c \right) \dot{\psi}_A \right] \bigg|_{T_R}. \quad (3.26)$$

At this stage, this correction is valid, similar to the quadrupole formula, for general closed orbits. We find a perfect match of these spinning corrections at linear order in the objects’ spins, with the classical derivation, (2.14), using the identity (A.1). The linear-in-spin scattering amplitude is universal [51, 111], therefore, so is the radiated gravitational field (3.26). Equivalently, the classical spin dipole of a point particle is universal, describing any spinning compact object at leading order. Therefore, non-universality of the waveform at
higher spin orders may enter only through a solution to the classical EoM for a particular compact binary system. We showed in §2.2.2 that the closed orbits waveform (2.14) contains all possible spin effects at leading order in the BHs’ velocities, before specializing the constituents’ trajectories; i.e., \( h_{TT,S}^{(0),ij} f_{T,S}^{\ell=2} = 0 \). Therefore, we expect to find cancellations at higher orders in spins at the level of the scattering amplitude for \( \ell > 1 \). Finally, as claimed above, there exists a one-to-one correspondence between source multipole moments and spinning scattering amplitudes: \( I_{ij} \leftrightarrow \langle M_{5,S0}^{(0)} ab \rangle \) and \( J_{ij} \leftrightarrow \langle M_{5,S1}^{(0)} ab \rangle \). This holds in the sense that both \( I_{ij} \) and \( \langle M_{5,S0}^{(0)} ab \rangle \) produce the quadrupole formula (and similarly for the linear-in-spin waveform).

### 3.3.3 Cancellations at quadratic order in spin

In the previous section, we showed that the gravitational waveform emitted from a spinning BBH at leading order in its velocities is entirely contained in the linear-in-spin radiation field (2.14). Equivalently, this waveform is obtained only using the scalar and linear-in-spin amplitude. The remaining all orders in spin result (2.18) emerges solely from the solution (2.7) for quasi-circular orbits. To confirm this from the scattering amplitudes perspective, we are left to show that higher spin amplitudes do not provide additional non-trivial contributions to the general closed orbit results presented above. In this section, we demonstrate the cancellation at the quadratic order in the BHs’ spins, by specializing to circular orbits and by focusing on the \( S_1 \neq 0, S_2 \rightarrow 0 \) limit.

At leading order in the BHs’ velocities, there are two distinct contributions to the radiated field from our approach. There is the quadratic-in-spin part of the amplitude on the one hand (which we provide in the ancillary Mathematica notebook for brevity), leading to \( T_{1,1}^{(0)}(k, z_1, z_2) \), and the scalar part (3.16) in conjunction with the quadratic-in-spin part of the classical EoM (2.5), yielding \( T_{2,2}^{(0)}(k, z_1, z_2) \). Both combine as

\[
T_{S_2}^{(0)}(k, z_1, z_2) = T_{1,1}^{(0)}(k, z_1, z_2) + T_{2,2}^{(0)}(k, z_1, z_2). \tag{3.27}
\]

Focusing first on the contribution from the quadratic-in-spin part of the amplitude, to leading order in \( v \) it reads

\[
\langle M_{5,S2}^{(0)} ab(\mathbf{q}, \bar{\omega}) \rangle = \frac{1}{4} i m_2^2 \kappa^3 S_1 S_1^l \left[ V_{kl,df}^{ab} \frac{q^d q^f}{2} + C_{kl}^{ab} \right], \tag{3.28}
\]

where we have defined the tensor \( V_{kl,df}^{ab} = \delta_{kl} \delta_{ab} - \frac{1}{2} \delta_{kd} \left( \delta_{lf} \delta_{bj} + \delta_{bj} \delta_{lf} \right) \), and \( C_{kl}^{ab} \) is a contact term, which we discard, as it is irrelevant for the gravitational waveform. As before, we insert this amplitude into the source (3.7), and perform the \( q \)-integrals aided by (A.3). The first contribution to the source \( T_{S_2}^{(0)}(k, z_1, z_2) \) is then

\[
T_{1,1}^{(0)}(k, z_1, z_2) = -\frac{1}{4} m_2 \kappa^3 m_1^2 \left. S_1 S_1^l V_{kl,df}^{ab} \int dt e^{i \bar{\omega} t} \frac{1}{r^5} \left[ p^2 \delta df - 3 z_{21} d f \right] \right) \tag{3.29}
\]

\[\text{Notice, the linear-in-spin part of the EoM is sub-leading in } v, \text{ and therefore, when convoluted with the linear-in-spin amplitude, the resulting quadratic in spin contribution is pushed to sub-leading order in velocities.}\]
Using the scalar part of the EoM (2.5) to remove three powers of \( r \) in the denominator, the above reduces to

\[
T_{1,LS}^{(0) ab}(k, z_1, z_2) = -\frac{m_2}{m_1} \kappa S^k_l S^l_j V_{kl,df} \int d\tau e^{i\omega t} \frac{1}{r^2} \left[ \left( \frac{\dot{v}_{12} + \dot{v}_{12}}{m_1} \right) \delta_{df} - \frac{1}{3} \left( \frac{\dot{v}_{12} + \dot{v}_{12}}{m_1} \right) \right],
\]

which, for quasi-circular orbits (2.15), reads

\[
T_{1,LS}^{(0) ab}(k, z_1, z_2)\bigg|_{\text{circular}} = -2\kappa \omega^2 \mu \bar{a}_1^2 \int d\tau e^{i\omega t} \left[ 2n^a n^b - \lambda^a \lambda^b \right]. \tag{3.31}
\]

Recall the definition for the symmetric mass ratio \( \mu = m_1 m_2 / M \), and \( \bar{a}_1 = S^k_l \ell_i / m_1 \), with \( \ell^i \) perpendicular to both \( n^i \) and \( \lambda^i \). Note, the solution to the classical EoM, \( r(x) \), in the numerator, cancels with the two powers of \( r \) in the denominator.

We now turn to the second contribution to the source: \( T_{2,S}^{(0) ij} \). To that end, we first rewrite (3.17) by expanding the sums and removing those terms that vanish under the TT projection:

\[
T_{2,S}^{(0) ab}(k, z_1, z_2) = -\kappa^3 \int d\tau e^{i\omega t} \frac{m_1 m_2 z_{12}}{16\pi r^3} \left[ \delta^{(a,b)}_{z_{12}} \pm \frac{2i}{\omega} \delta^{(a,b)}_{v_{12}} \right]. \tag{3.32}
\]

Next we use the classical EoM to quadratic order in spin, which can be written in the following form (see Appendix B)

\[
\dot{v}_i^l = -\frac{m_2 \kappa}{32\pi} \frac{z_{12}^l}{r^3} + \frac{3}{4} \frac{S^k_l S^l_j}{m_1^2 r^2} \left[ \left( \frac{\delta_{ij} - \frac{5 z_{12}^i z_{12}^j}{r^2}}{r^2} \right) \left( v_1^l - \frac{m_1}{m_1} v_2^l \right) + 2 \delta_{ij} \left( \dot{v}_{1,j} - \frac{m_1}{m_1} \dot{v}_{2,j} \right) \right]. \tag{3.33}
\]

Combining this with (3.32), the scalar part will recover the Einstein quadrupole radiation formula (3.22). We stress that although the quadrupole formula appears to be spin-independent for general orbits, spin information arises through a specific solution to the EoM, as pointed out above. In particular, for quasi-circular orbits the Einstein quadrupole formula provides the quadratic-in-spin result (2.18). Let us, therefore, focus in the remaining contribution of (3.33), which is

\[
T_{2,S}^{(0) ab}(k, z_1, z_2) = -\frac{3}{4} \kappa S^k_l S^l_j \int d\tau e^{i\omega t} \left[ \delta^{(a,b)}_{z_{12}} + \frac{2i}{\omega} \delta^{(a,b)}_{v_{12}} \right] \times \frac{1}{m_1 r^2} \left[ \left( \delta_{kl} - \frac{5 z_{12,k} z_{12,l}}{r^2} \right) \left( v_1^c - \frac{m_2}{m_1} v_2^c \right) + 2 \delta^{(c)}_k \left( \dot{v}_{1,l} - \frac{m_2}{m_1} \dot{v}_{2,l} \right) + \frac{m_2}{m_1} (1 \leftrightarrow 2) \right]. \tag{3.34}
\]

Using the center of mass parametrization\(^\text{17}\) (2.6), the quasi-circular orbits condition \( \bar{r} = -\bar{\omega} r \), and the unit vectors (2.15), the source reduces to

\[
T_{2,S}^{(0) ab}(k, z_1, z_2)\bigg|_{\text{circular}} = 3\kappa \omega^2 \mu \bar{a}_1^2 \int d\tau e^{i\omega t} \left[ n^a n^b + i(\lambda^a n^b + \lambda^b n^a) \right]. \tag{3.35}
\]

\(^\text{17}\)Note, the linear-in-spin corrections of this parametrization is sub-leading in velocities.
In order to remove the imaginary part of the source, we proceed as before and use an IBP prescription. Notice, since \((\lambda^a n^b + \lambda^b n^a) = -\frac{1}{\omega} \frac{d}{dt} (\lambda^a \lambda^b)\), the IBP yields

\[
T^{(0)ab}_{2,S^2}(k, z_1, z_2) \big|_{\text{circular}} = 3\kappa\tilde{\omega}^2 \mu_0^2 \int dt e^{i\tilde{\omega} t} \left[ n^a n^b - \lambda^a \lambda^b \right]. \tag{3.36}
\]

This has the familiar form found in (2.18). Unlike this form, in (3.31) an extra factor of two appears in the \(n^a n^b\) term. This obscures the desired cancellation between (3.36) and (3.31) in \(T^{(0)ij}_{S^2}\). To address this subtlety, we emphasize the degeneracy in choice of the IBP prescription. Notice, since the first relativistic correction, in our Born approximation, as coming from the arguments made above in §3.1 concerning the time integration still holds. In this case, however, the first relativistic correction, in our Born approximation, as coming from the product of the plane wave functions in (3.5), appears in the source through the kinematic exponential \(e^{-ik\cdot z}\), and therefore contributes to the sub-leading source \(T^{(1)ab}_{S^0}\), due to the scaling \(\tilde{\omega} \sim v\). That is, after time integration, the exponential function reduces as \(e^{ik\cdot z} \to 1 - i\tilde{\omega} N \cdot \tilde{z} + O(v^2) = 1 - \frac{i}{2} \tilde{\omega} N \cdot (z_1 + z_2) + O(v^2)\); hence, the source is built from the order-\(v^0\) non-spinning scattering amplitude, \(T^{(1)ab}_{2,S^0}\), as well as from the \(v^1\)-amplitude, \(T^{(1)ab}_{1,S^0}\). More concretely, the sub-leading source decomposes as\(^{18}\)

\[
T^{(1)ab}_{S^0}(k, z_1, z_2) = T^{(1)ab}_{1,S^0}(k, z_1, z_2) + T^{(1)ab}_{2,S^0}(k, z_1, z_2), \tag{3.37}
\]

\(^{18}\)In principle, the classical EoM (2.5) also contain higher-order-in-\(v\) corrections, which could be used in an iterative manner, starting purely from the leading in \(v\)-scalar amplitude. However, these velocity corrections vanish in the no-spin limit considered in this section.

3.3.4 Scalar waveform at sub-leading order in velocities

So far we have dealt with leading in BHs’ velocities spinning corrections to the Einstein quadrupole formula (3.22). In this section, we go beyond this restriction and consider a non-spinning BBH at the first sub-leading order in velocities, therefore, demonstrating the applicability of our approach (3.1) to determine the radiated gravitational waves also in this regime. At this order, the scalar 5-pt amplitude is also independent of \(q^0\), therefore, arguments made above in §3.1 concerning the time integration still holds. In this case, however, the first relativistic correction, in our Born approximation, as coming from the product of the plane wave functions in (3.5), appears in the source through the kinematic exponential \(e^{-ik\cdot z}\), and therefore contributes to the sub-leading source \(T^{(1)ab}_{S^0}\), due to the scaling \(\tilde{\omega} \sim v\). That is, after time integration, the exponential function reduces as \(e^{ik\cdot z} \to 1 - i\tilde{\omega} N \cdot \tilde{z} + O(v^2) = 1 - \frac{i}{2} \tilde{\omega} N \cdot (z_1 + z_2) + O(v^2)\); hence, the source is built from the order-\(v^0\) non-spinning scattering amplitude, \(T^{(1)ab}_{2,S^0}\), as well as from the \(v^1\)-amplitude, \(T^{(1)ab}_{1,S^0}\). More concretely, the sub-leading source decomposes as\(^{18}\)

\[
T^{(1)ab}_{S^0}(k, z_1, z_2) = T^{(1)ab}_{1,S^0}(k, z_1, z_2) + T^{(1)ab}_{2,S^0}(k, z_1, z_2), \tag{3.37}
\]

\(^{18}\)In principle, the classical EoM (2.5) also contain higher-order-in-\(v\) corrections, which could be used in an iterative manner, starting purely from the leading in \(v\)-scalar amplitude. However, these velocity corrections vanish in the no-spin limit considered in this section.
where
\[ T_{1,S_0}^{(1)ab}(k, z_1, z_2) = \frac{i}{m_1 m_2} \int dt e^{i \omega t} \int \frac{d^3 q}{(2\pi)^3} e^{-i q \cdot z_{21}} \langle M_{5,S_0}^{(1)ab}(q, \bar{\omega}) \rangle, \tag{3.38} \]
and
\[ T_{2,S_0}^{(1)ab}(k, z_1, z_2) = \frac{1}{m_1 m_2} \int dt e^{i \omega t} \int \frac{d^3 q}{(2\pi)^3} e^{-i q \cdot z_{21}} \frac{\bar{\omega}}{2} N \cdot (z_1 + z_2) \langle M_{5,0}^{(0)ab}(q, \bar{\omega}) \rangle. \tag{3.39} \]

Notice the superscripts in the amplitude. First, we focus on the relativistically corrected scalar amplitude. Analogous to before, we insert (3.13) into (3.8), but now keep the non-trivial order \( O(v^4) \) contributions to the 5-pt amplitude:
\[ \langle M_{5,S_0}^{(1)ab}(q, \bar{\omega}) \rangle = -\frac{im^3 m_2^2 \kappa^3}{2} N_i \left[ \frac{q^l q^m}{q^4} \delta_m^{(a)} (v_1 + v_2)^b + \frac{q^l}{2\omega q^2} (v_1^a v_2^b - v_2^a v_1^b) \right] \]
\[ + \frac{q^m}{\omega q^2} \left( v_1^l v_2^a \delta_m^b - v_2^l v_1^a \delta_m^b \right). \tag{3.40} \]

Subsequently, the source (3.38), after the \( q \)-integration, takes the form
\[ T_{1,S_0}^{(1)ab}(k, z_1, z_2) = \frac{\kappa^3}{16\pi} \frac{m_A m_B}{r^3} \left[ -\frac{1}{2} \left( z_{AB}^2 \delta_m^{lm} - z_{AB}^m z_{AB}^l \right) \delta_m^{(a)} (v_A + v_B)^b \right] \]
\[ - \frac{i}{\omega} z_{AB}^n \left( \delta_m^{l} v_{A}^a v_{A}^b + 2 \delta_m^{m} v_{A}^l (a b) \right). \tag{3.41} \]

In order to remove the powers of \( z_{AB} \sim r \) in the denominator, we use the scalar part of the EoM (2.5), to obtain
\[ T_{1,S_0}^{(1)ab}(k, z_1, z_2) = 2\kappa N_i \int dt e^{i \omega t} \left[ - \frac{1}{2} \sum_{A,B} m_A \left( \hat{v}_A \cdot z_{AB} \delta_m^{lm} - i \hat{v}_A^m z_{AB}^l \right) \delta_m^{(a)} (v_A + v_B)^b \right] \]
\[ + \frac{i}{\omega} \sum_{A} m_A \hat{v}_A^m \left( \delta_m^{l} v_{A}^a v_{A}^b + 2 \delta_m^{m} v_{A}^l (a b) \right). \tag{3.42} \]

The term in the second line can be integrated utilizing the relation \( \hat{v}_A^m \left( \delta_m^{l} v_{A}^a v_{A}^b + 2 \delta_m^{m} v_{A}^l (a b) \right) = \frac{d}{dt} (v_A^l v_A^a v_A^b) \). With this, this piece of the sub-leading scalar source simplifies to
\[ T_{1,S_0}^{(1)ab}(k, z_1, z_2) = -2\kappa N_i \int dt e^{i \omega t} \left[ \sum_{A,B} m_A \left( \hat{v}_A \cdot z_{AB} \delta_m^{lm} - i \hat{v}_A^m z_{AB}^l \right) \delta_m^{(a)} (v_A + v_B)^b \right] \]
\[ - \sum_{A} m_A \hat{v}_A^m v_{A}^a v_{A}^b. \tag{3.43} \]

We now address the second term in (3.37) – the computation of the second contribution (3.39) to the sub-leading scalar source. The \( q \)-integration is identical to the one used
leading up to (3.18). Starting from the latter, using the relation (3.19), and multiplying
the sub-leading prefactor $-\frac{i}{2}\bar{\omega}N^{-1}(z_1 + z_2)$ we arrive at
\[
\mathcal{T}^{(1)}_{2,S_0}(k, z_1, z_2) = -\kappa \int dt e^{i\bar{\omega} t} N^{-1}(z_1 + z_2) \sum_A m_A \left[ i\bar{\omega}\bar{z}^{(a,b)}_A - 2v^{(a,b)}_A \right]. \tag{3.44}
\]
Lastly, with the replacement $\bar{\omega} \rightarrow i\frac{d}{dt}$ the first term is integrated. The gravitational radiation field is then determined by putting the two sources together in (3.37), and substituting this into (3.1), to end up at the first sub-leading in BH velocities non-spinning correction to the Einstein quadrupole formula:
\[
h^{(1)ij}_{TT,S_0}(T_R, R, N, z_1, z_2) = -\frac{\kappa^2 m_1}{8\pi R^4} \Pi^{ij}_{ab} N_l \left[ \frac{1}{2} \left( \dot{v}_1 \cdot z_{12} \right) \delta^{a_m}(v_1 + v_2)^b - v_1^a v_1^b \right. \\
- \left. \left( \frac{1}{2} \frac{d}{dt} \left( \bar{z}^{(a,b)}_1 (z_1 + z_2) \right) + 2(z_1 + z_2)v_1^a v_1^b \right) \right] + (1 \leftrightarrow 2). \tag{3.45}
\]
Based on our derivation, this result is valid for generic closed orbits, provided the corresponding EoM. However, the form of this waveform is different from the compact classical result in (2.21). This is not surprising since, as illustrated above, there is always the freedom of choice of IBP prescription, which casts the waveform into different forms. Finding the prescription, for which both the amplitude’s and the classical waveforms match, could be cumbersome for generic closed orbits. Therefore, we specialize to the quasi-circular setting (2.15); In the latter, we find perfect agreement between (3.45) and (2.21). We close with a remark on the correspondence between the classical source multipole moments leading to the gravitational radiation via the multipolar post-Minkowskian approach, and our ansatz to compute the associate gravitational waves using spinning scattering amplitudes. We saw in §2.2.2, the sub-leading order result (2.20) is built from both $I_{ijk}$ and $J_{ij}$. While at leading order in the BHs’ velocities (see §3.3.2), there exists a certain one-to-one correspondence between the source multipole moments, at sub-leading orders in velocities, no trivial correspondence can be extracted from our results.

### 3.4 Radiated gravitational wave energy flux

In the previous sections, we showed explicitly that the radiated gravitational field, $h^{TT}_{ij}$, computed using a classical approach and utilizing a 5-pt spinning scattering amplitude, agree in the aligned spin, general (and quasi-circular) orbit setup at the considered orders in the velocity and spin expansions. These are the gravitational waves emitted at an instant in the binary’s evolution. Information about the frequency dynamics of the radiation is contained in the emitted gauge invariant gravitational wave energy flux. The latter is ultimately responsible for the inspiral of the two BHs and for the characteristic increase in gravitational wave frequency towards the merger, therefore, a crucial ingredient for gravitational wave search strategies.

In this section, we derive the instantaneous gravitational wave energy flux $\mathcal{F}$ using the TT metric perturbations at null infinity computed in the previous subsections to the
Let us return here to the justification for the replacements and claims made in §3.3.3. The time dependence of \( h_{ij}^{TT} \) is solely contained in the center of mass variables \( n^a \) and \( \lambda^a \), which, in the center of mass frame and for circular orbits, are related by

\[
\frac{d}{dt}(n^an^b) = \frac{1}{2} \frac{d}{dt}(n^an^b - \lambda^a\lambda^b).
\]

Since only the time derivative of the radiated field, \( \dot{h}_{ij}^{TT} \), enters in (3.46), this justifies the replacement \( n^an^b \to \frac{1}{2}(n^an^b - \lambda^a\lambda^b) \) made in §3.3.3 at the level of the radiated field. Furthermore, this also shows that the gauge invariant energy flux is, in fact, independent of the IBP prescription discussed in §3.3.3. Therefore, the latter can be viewed as a manifestation of the gauge freedom in the emitted waveform. Indeed, this extends to the Newman-Penrose scalar \( \Psi_4 \sim \bar{m}^\mu \bar{m}^\nu h_{\mu\nu}^{TT} \) in an identical fashion. Exploiting this, the gravitational wave energy flux is obtained by combining the scalar, (3.22), and linear-in-spin, (3.26), metric perturbations \( h_{ij}^{TT} \) at leading order in the BHs’ velocities, in (3.46). For quasi-circular orbits (2.7), together with (A.2), we find the energy loss

\[
F_{circular}^{(0)} = \frac{32}{5} \frac{\mu^2 x^5}{M^2} + \frac{2}{5} \frac{\mu^2 x^7}{M^2} (32a_2^2 + a_1^2) + \mathcal{O}(a_1^3, a_2^3). \tag{3.47}
\]

Recall from above that \( x = (M\omega)^{2/3} \). This matches perfectly with the results reported in Refs. [87, 92, 94, 105–107] to the respective orders in spin. In addition to this match at leading order in the black holes velocities, the metric perturbations computed in (3.45) and (2.21) specialized to circular orbits reproduce the correct no-spin gravitational wave energy flux \( F_{circular}^{(1)} = 0 \) at the first sub-leading order in velocities; this is, again, consistent with the leading no-spin PN gravitational wave power (see, e.g., [107]). Notice, we explicitly computed the quadratic-in-spin contributions only for one BH with spin: \( S_1 \neq 0, S_2 \to 0 \). However, as noted above, the classical derivation in §2.2.2 revealed that the high-order-in-spin contributions to the circular orbit \( h_{ij}^{TT} \) emerge solely from the solution to the EoM, indicating that (3.47) already contains the \( a_1a_2 \)-type interactions; this is the case, as can be seen in, for instance, [92, 94], or from using (2.17) together with (3.46). At the level of the transverse traceless metric perturbations \( h_{ij}^{TT} \), the classical derivation showed that (2.14) contains the complete all-orders-in-spin information at leading order in velocities, since the remaining contributions to the radiation field – i.e. \( h_{ij}^{(0)TT} = 0 \) – vanish, without a specific solution to the EoM. In the scattering amplitudes setting, we confirmed this explicitly up to \( \ell = 1 \), since (3.22) and (3.26) agree with (2.14) (exploiting (A.1)), and we showed the necessary cancellation for \( \ell = 2 \) in §3.3.3. Therefore, we conjecture such cancellations to occur at arbitrary order in spin, such that the solution to the EoM provides the remaining spin-information, at leading order in velocities. The complete all-orders in spin gravitational power result partially presented in (3.47) was determined in [94].

4 Discussion

We studied the relationship between the radiative dynamics of an aligned-spin spinning binary black hole from both, a classical, and a scattering amplitude perspective. For the
former we employed the multipolar post-Minkowskian formalism, whereas for the latter we proposed a dictionary built from the 5-pt QFT scattering amplitude. More precisely, the dictionary maps the classical limit of the 5-pt scattering amplitude of two massive spinning particles exchanging and emitting a graviton, to the source entering in Einstein’s equation. Furthermore, we included information of the conservative dynamics using the classical equations of motion. We worked in linearized gravity, i.e., at tree-level, and to leading order in the black holes’ velocities, but to all orders in their spin, as well as present preliminary results at sub-leading orders in velocities (in the no-spin limit). To leading order in the system’s velocities, we showed that there exist a one-to-one correspondence between the source’s multipole moments, and the scattering amplitudes. That is, the mass quadrupole in (2.13) corresponds to the scalar amplitude (3.16), while similarly, the current quadrupole in (2.13) is associated with the linear-in-spin amplitude (3.23). This correspondence was made explicit in the computation of the transverse-traceless part of the linear metric perturbations emitted to null infinity, as well as on the gauge invariant gravitational wave energy flux. The latter agrees for quasi-circular orbits with the existing literature [92, 94, 106, 107], both at the considered leading and sub-leading orders in the black holes’ velocities. Therefore, gravitational waveforms and gauge invariant powers needed for detecting gravitational waves from inspiraling black holes can be consistently computed from the classical limit of quantum scattering amplitudes.

The gravitational waveform is, in general, a gauge-dependent object, which makes a comparison between the classical and the scattering amplitude’s derivations potentially difficult. In particular, and especially for general orbits and with spin effects, finding the corresponding gauge to undertake such comparisons can become cumbersome. In this work, we found evidence that such gauge freedom is related to the integration procedure used in the source for Einstein’s equation, within the scattering amplitudes derivation. We demonstrated this explicitly for quasi-circular orbits, as this restriction simplifies the problem drastically. Importantly, we find that while the form of the gravitational radiation field is dependent upon the integration procedure used, the gauge-invariant gravitational wave power is independent of such a prescription – as desired.

In this work, we focused entirely on the derivation of radiative degrees of freedom from the 5-pt scattering amplitude, while using a classical derivation of the system’s conservative equations of motion. However, the conservative sector can efficiently be solved also, utilizing 4-pt scattering amplitudes. Therefore, one can envision combining 4-pt and 5-pt scattering amplitudes in such a way, as to remove the need for explicitly supplying the classical equations of motion. This might provide a pathway to deriving a gauge-invariant definition of the black holes’ worldlines from the 5-point scattering amplitude in (3.2) that is entirely self-contained. In fact, for scalar sources, it was observed in Ref. [70] that the 4-pt graviton exchange amplitude satisfies the bodies’ classical equations of motion suggesting such a relation. We leave exploring this avenue to future work.

The amplitudes-based construction of the radiated field (3.1), provided in this work, has implicitly used the on-shell condition for the outgoing massive particles $\delta(p_i \cdot q_i)$, which discards terms quadratic in the velocities as indicated by the quantum corrections to the particles trajectories $z_Q(\tau_i)$ in (3.4). These corrections can become important if convoluted
with superclassical terms coming from loop amplitudes. This then hints that at higher orders in perturbation theory, a subtraction scheme would be needed to cancel those superclassical contributions at the level of the gauge invariant observable, which in this case corresponds to the radiated energy flux $F \sim \int d\omega \hat{h}^{ij} \dot{h}_{ij}$; in addition, it would be desirable to study the connection of our approach and that of analytic continuation methods of scattering observables [18, 19, 53] .

Besides, exploring gauge fixing procedures that allow to match the general orbit result (3.45) to the classical result (2.21), as well as the inclusion of spin effects at sub-leading order in velocity is left for future work. Furthermore, in the context of scattering amplitudes, higher orders in velocities are naturally included. However, for closed orbits, these corrections are consistent only – by virtue of the virial theorem – when also higher orders in the gravitational constant $G$ are considered. For instance, at quadratic order in the BHs’ velocities, the radiated field could contain contributions from both the tree-level and the one-loop 5-pt scattering amplitudes. One might wonder whether the amplitudes approach could reproduce the higher-order corrections to the energy flux for non-spinning binary black holes [3].

Finally, the source (3.2) was written in the Born approximation, where the initial state consists of two particles in their plane-wave states. However, the long-range nature of the gravitational interactions renders the Born approximation to be invalid in this setting. Although this is expected to be a higher-$G$-effect (or equivalently a higher-$v$-effect in the closed orbit case), it plays an important role in the determination of the correct gravitational waveform. A modification to the Born approximation was proposed in [70], and claimed to contain all non-perturbative aspects of the S-matrix elements. We leave the exploration of this proposal for future work.

**A Useful integrals and identities**

Here we write out the identity used in §3.3.2 for the comparison of the gravitational waveforms at linear order in spin. That is, given two vectors $a^i$ and $b^i$, and the TT projector
defined in (2.16), we have [105, 107]

\[ \Pi^{ab}_{ij}b^j\varepsilon^i_{kl}\alpha^kN^\ell = \Pi^{ab}_{ij}\alpha^i_{kl}\varepsilon^kN^\ell. \]  

(A.1)

Furthermore, the following integrals were used during the computation of gravitational radiation from the amplitudes perspective:

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{1}{q^2} = \frac{1}{4\pi|z|}, \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i}{q^2} = \frac{i\varepsilon^i}{4\pi|z|^3}, \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i q^j}{q^2} = \frac{1}{4\pi|z|^5} \left[ |z|^2 \delta^{ij} - 3z^i z^j \right], \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i q^j q^k}{q^4} = \frac{1}{8\pi|z|^5} \left[ |z|^2 \delta^{ij} - z^i z^j \right], \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i q^j q^k q^l}{q^4} = -\frac{i}{8\pi|z|^5} \left[ |z|^2 \left( z^i \delta^{jk} + z^j \delta^{ik} + z^k \delta^{ij} \right) - 3z^i z^j z^k \right]. \]

(A.3)

In addition, the following integrals were used during the computation of gravitational radiation from the amplitudes perspective:

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{1}{q^2} = \frac{1}{4\pi|z|}, \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i}{q^2} = \frac{i\varepsilon^i}{4\pi|z|^3}, \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i q^j}{q^2} = \frac{1}{4\pi|z|^5} \left[ |z|^2 \delta^{ij} - 3z^i z^j \right], \]

\[ \int -\frac{d^3q}{(2\pi)^3} e^{iq\cdot z} \frac{q^i q^j q^k}{q^4} = \frac{1}{8\pi|z|^5} \left[ |z|^2 \delta^{ij} - z^i z^j \right], \]

(B.1)

Furthermore, we use these equations recursively, to remove powers of $1/r$\textsuperscript{19}. Since we are interested in the quadratic-in-spin contribution only, we consider only the scalar part of (B.1) (as well as the analogous equation for $v^i_2$) to rewrite (B.2) as follows

\[ \partial^i \partial_j \frac{1}{r} \rightarrow -\frac{32\pi}{\kappa^2} \frac{3}{2m_2 r^2} \left[ \delta_{ij} - \frac{5z_{12,i}z_{12,j}}{r^2} \right] \left( \hat{v}^i_1 - \frac{m_2}{m_1} \frac{v^i_2}{v^2_2} \right) + O(S^2_1), \]  

(B.3)

\textsuperscript{19}By restoring Newton's constant $G$, the equations of motion can be used to remove powers of $G$ in the numerator.
Notice a factor of 1/3 arises from symmetrization. This, then finally allows us to write the quadratic-in-spin equations of motion as

\[ \dot{v}_1^l = -\frac{m_2 \kappa^2}{32 \pi} \frac{z_{12}^l}{r^3} + \frac{3}{4} \frac{S_i^l S_j^l}{m_1^2 r^2} \left[ \left( \delta_{ij} - \frac{5 z_{12,i} z_{12,j}}{r^2} \right) \left( \dot{v}_1^l - \frac{m_2}{m_1} \dot{v}_2^l \right) + 2 \delta^l_{(i} \left( \dot{v}_{1,j} - \frac{m_1}{m_2} \dot{v}_{2,j} \right) \right] . \]  
(B.4)

And analogously we also find

\[ \dot{v}_2^l = \frac{m_1 \kappa^2}{32 \pi} \frac{z_{12}^l}{r^3} + \frac{3}{4} \frac{S_i^l S_j^l}{m_2^2 r^2} \left[ \left( \delta_{ij} - \frac{5 z_{12,i} z_{12,j}}{r^2} \right) \left( \dot{v}_2^l - \frac{m_1}{m_2} \dot{v}_1^l \right) + 2 \delta^l_{(i} \left( \dot{v}_{2,j} - \frac{m_2}{m_1} \dot{v}_{1,j} \right) \right] . \]
