THE DISCRIMINANT OF AN ALGEBRAIC TORUS

RONY A. BITAN

ABSTRACT. For a torus $T$ defined over a global field $K$, we revisit an analytic class number formula obtained by Shyr in the 1970’s as a generalization of Dirichlet’s class number formula. We prove a local-global presentation of the quasi-discriminant of $T$, which enters into this formula, in terms of cocharacters of $T$. This presentation can serve as a more natural definition of this invariant.

INTRODUCTION

The well-known class number formula expresses the class number of a number field $K$ in terms of other arithmetic invariants of $K$:

$$h = \frac{w|\Delta|^{1/2} \rho}{2^r (2\pi)^t R}$$

where $w$ is the number of roots of unity in $K$, $\Delta$ is the discriminant of $K$, $\rho$ is the residue of the Dedekind Zeta-function of $K$ at $s = 1$, $R$ is the regulator of $K$ and $r$ (resp. $t$) is the number of real (resp. pairs of complex) embeddings of $K$.

In the early 1960’s, T. Ono defined in [Ono] analogues of these invariants for algebraic tori defined over both kinds of global fields, namely, the number field case (denoted by case (N)) and the case of algebraic function field in one variable over a finite field of constants $\mathbb{F}_q$ (denoted by case (F)). One of these invariants is the quasi-discriminant. As in the case of the discriminant of a global field, the quasi-discriminant of $T$ is the volume of the fundamental domain of the maximal compact subgroup of $T(A_K)/T(K)$ – where $A_K$ is the adele ring – with respect to the Tamagawa measure. J. M. Shyr gave in [Shyr1] a similar definition in the case of algebraic $\mathbb{Q}$-tori. In this new construction, other arithmetic invariants are taken from Ono’s definition. This led him to a relation which can be viewed as an “analogue of the class number formula” for algebraic $\mathbb{Q}$-tori. This relation can be generalized to tori defined over any global field $K$, as follows:

$$c_T^{\text{Shyr}} := |\Delta_K|^{-d/2} C_\infty \prod_p L_p(1, \chi_T) \cdot \omega_p(T_p(O_p)) = \frac{\rho \tau T \omega T}{h_T R_T}$$  (0.1)

where $C_\infty$ is an archimedean factor and $\Delta_K$ is the discriminant of $K$, $d = \dim T$. For any prime $p$ of $K$, $K_p$ is the complete localization of $K$ at $p$, $T_p = T \otimes K_p$, $T_p(O_p)$ is the maximal compact subgroup of $T_p(K_p)$, $L_p(s, \chi_T)$ is the local Artin $L$-function and $\omega_p$ is some Haar measure on $T_p(K_p)$.

A part of a Ph.D. Thesis supervised by B. Kunyavskii at the Department of Mathematics, Bar-Ilan University, Ramat-Gan, Israel. Partially supported by the ISF center of excellency grant 1438/06.
\( \rho_T \) is the residue of the global Artin \( L \)-function at \( s = 1 \), \( w_T \) is the cardinality of the torsion part of the group of units of \( T \), \( h_T \) is the class number of \( T \), \( R_T \) is the regulator of \( T \) (equal to 1 in case(F)), and \( \tau_T \) is the Tamagawa number of \( T \). This work is described in the fourth Section and on the Appendix. We call \( c_T^{\text{Shyr}} \) the Shyr invariant.

Locally, let \( K \) be a henselian local field with a ring of integers \( \mathcal{O}_p \) and a finite residue field \( k \). Let \( T \) be an algebraic \( K \)-torus splitting over a finite Galois extension \( L/K \) with Galois group \( \Gamma \). We investigate the invariant \( L_p(1, \chi_T) \cdot \omega_p(T(\mathcal{O}_p)) \). Ono defined the group \( T(\mathcal{O}_p) \) using the dual \( \Gamma \)-module, namely its group of characters. In order to measure it, we would like to describe it as a group of \( \mathcal{O}_p \)-points of some integral model. In the first Section we exhibit the properties and relation between two integral models of \( T \), namely, the standard integral model \( X \) defined by V. E. Voskresenskii (which is of finite type), and the well-known Néron-Raynaud integral model \( T \), (which is locally of finite type). After applying a smoothening process to \( X \), the identity components of both models coincide. Let \( \Phi_T \) be the \( k \)-scheme of the group of components of the reduction of \( T \) modulo \( p \). In the second Section we prove that:

\[
L_p(1, \chi_T) \cdot \omega_p(T(\mathcal{O}_p)) = |\Phi_T(k)_{\text{tor}}|.
\]

In the third Section, we use a construction of Kottwitz in [Ko], to prove an isomorphism of \( k \)-schemes \( \Phi_T(k) \cong (X^\bullet(T)_I)^{(F)} \) where \( X^\bullet(T) \) is the cocharacter group of \( T \), \( I \) is the inertia subgroup of \( \Gamma \) and \( F \) is the Frobenius automorphism generating \( \Gamma/I \). This isomorphism gives us another computation of the local component in Shyr’s invariant:

\[
L_p(1, \chi_T) \cdot \omega_p(T_p(\mathcal{O}_p)) = |\ker (1 - F)|_{\chi^\bullet(T)_I}_{\text{tor}}|.
\]

Globally, together with the infinite place information, we prove in the fourth Section our main Theorem, which can be viewed as a local-global result, in spirit of the Artin-Hasse conductor-discriminant formula:

**Main Theorem.**

\[
c_T^{\text{Shyr}} = |\Delta_K|^{-d/2} C_\infty \prod_p |\ker (1 - F_p) X^\bullet(T_p)_{I_p})_{\text{tor}}| = \frac{\rho_T \tau_T w_T}{h_T R_T}.
\]

From this formula one can see that the Shyr invariant can be decomposed into the product of the “arithmetic-geometric part” (related to the discriminant of the ground field) and the “algebraic” part (reflecting the Galois action on the cocharacters).

**Acknowledgments.** I thank B. Kunyavskiĭ for his guidance and support. I also thank Q. Liu, T. Richarz and the referee for helpful comments.
1. Integral models of algebraic tori

Let $K$ be any field. An algebraic torus $T$ is an algebraic $K$-group such that $T \otimes_K L \cong \mathbb{G}_m^d$ for some finite Galois extension $L/K$ where $\mathbb{G}_m$ is the multiplicative group and $d$ is the dimension of $T$. The smallest among such extensions is called the splitting field of $T$. We write $T \in \mathcal{C}(L/K)$. We denote by $X^•(T) = \text{Hom}(T \otimes_K L, \mathbb{G}_m)$ the group of characters of $T$. For any intermediate field $K \subseteq F \subseteq L$, $X^•(T)_F$ is the sublattice of characters defined over $F$.

Now let $K$ be a local field which is the complete localization of a global field with respect to a prime $p$. We denote by $\mathcal{O}_p$ the ring of integers of $K$ and by $U_p = \mathcal{O}_p^\times$ its subgroup of units. Let $k = \mathcal{O}_p/p$ be the residue field with cardinality $q$. Let $T \in \mathcal{C}(L/K)$ and denote by $\Gamma = \text{Gal}(L/K)$ the Galois group and by $I$ its inertia subgroup.

An $\mathcal{O}_p$-integral model of $T$ is an $\mathcal{O}_p$-scheme $M$ whose generic fiber $M \otimes_{\mathcal{O}_p} K$ is isomorphic to $T$. The reduction modulo $p$ of $M$ is its special fiber $M_p = M \otimes_{\mathcal{O}_p} k$. Its identity component $M_0$ is an open subscheme of $M$ which is the identity component of the special fiber, i.e. such that $M_0 \otimes k = (M \otimes k)^0$ (see [BLR, p.154]).

T. Ono defined $T(\mathcal{O}_p)$ as the maximal compact subgroup of $T(K)$ with respect to the $p$-adic topology. This was done using the group of characters (see [Ono, 2.1.3]):

$$T(\mathcal{O}_p) = \{ x \in T(K) : \chi(x) \in U_p \forall \chi \in X^•(T)_K \}.$$  

However, in order to measure this group with respect to some local measure, this description may not be enough. We would like to write $T(\mathcal{O}_p)$ as the group of $\mathcal{O}_p$-points of some group scheme. Toward this end, we consider two integral models of $T$.

1.1. The standard integral model. The following construction is due to V. E. Voskresenskii and can be found in [Pop, §1]. Notations are as above and suppose that $(L : K) = n$ and $\dim T = d$. Then $X^•(T)$ is spanned as a $\mathbb{Z}$-lattice by a basis $\{ \chi_i \}_{i=1}^d$. The Hopf algebra $B = (L[X^•(T)])^\Gamma$ is the coordinate ring of $T$. The isomorphism $T \otimes_K L \cong \mathbb{G}_m^d$ is equivalent to the isomorphism of $L$-algebras: $B \otimes_K L = LB \cong L[X^•(T)]$. Let $\{ \omega_i \}_{i=1}^n$ be an integral basis of $L$ over $K$. Then

$$L[X^•(T)] = B\omega_1 \oplus \ldots \oplus B\omega_n.$$  

Thus there are linear combinations:

$$\chi_i = x_i^{(1)} \omega_1 + \ldots + x_i^{(n)} \omega_n, \quad x_i^{(j)} \in B$$

$$\chi_i^{-1} = y_i^{(1)} \omega_1 + \ldots + y_i^{(n)} \omega_n, \quad y_i^{(l)} \in B.$$
**Definition 1.** $A(X^\bullet(T)) = \mathcal{O}_p[x_i^{(j)}, y_m^{(l)}]$ is a Hopf $\mathcal{O}_p$-algebra. The group $\mathcal{O}_p$-scheme $X = \text{Spec} A(X^\bullet(T))$ is called the standard integral model of $T$.

**Remark 1.1.** ([Vos, § 10.3]) Being obtained from a linear representation, $X$ is of finite type over $\mathcal{O}_p$, and is reduced and faithfully flat. Further, $X(\mathcal{O}_p) = T(\mathcal{O}_p)$ is the maximal compact subgroup of $T(K)$ with respect to the $p$-adic topology.

**1.2. The Néron-Raynaud integral model and relations to the standard model.** Let $K_{sh}$ be the strict henselization of $K$ and $\mathcal{O}_{sh}$ be its ring of integers. We refer to the Néron-Raynaud (NR for short) model $T$ of $T$ which is locally of finite type over $\mathcal{O}_{sh}$, as defined in [BLR, ch. 10] and satisfying $T(\mathcal{O}_{sh}) = T(K_{sh})$.

**Remark 1.2.** A local ring is strictly henselian if its residue field is separably closed. In our cases (N) and (F) the residue field of any complete localization is perfect, thus $K_{sh}$ is the maximal unramified extension of $K$ and it is a Galois over $K$. Let $\Gamma_{sh} = Gal(K_{sh}/K)$. The $\Gamma_{sh}$-invariant subgroup of $T(\mathcal{O}_{sh}) = T(K_{sh})$ is then $T(\mathcal{O}_p) = T(K)$. Indeed, as $T$ is separated, the canonical map $T(\mathcal{O}_p) \to T(K)$ is injective. It is also surjective by the universal property of the NR-model.

The following construction can be found in [VKM]. Let $T_L = T \otimes L \cong G_{d,L}$. Let $\mathcal{O}_\Phi$ be the ring of integers of $L$ and let $T_L$ be the NR-model of $T_L$ defined over it. The $\mathcal{O}_\Phi$-scheme $S = R_{\mathcal{O}_\Phi/\mathcal{O}_p}(T_L)$ obtained by the Weil restriction of scalars, is the NR-model of $R = R_L/K(T_L)$. Its identity component is $S^0 = R_{\mathcal{O}_\Phi/\mathcal{O}_p}(\mathbb{G}_{m,\mathcal{O}_\Phi})$. Let $\mathcal{N}$ be the schematic closure of $T$ in $S$ induced by the canonical embedding $T \to R$. The standard $\mathcal{O}_\Phi$-model $X$ of $T$ is isomorphic to $\mathcal{N} \cap S^0$ (see [VKM, Prop. 6], the proof there is for $p$-adic fields but the arguments are valid also in case (F)).

**Lemma 1.3.** $X^0 = \mathcal{N}^0$.

**Proof.** $\mathcal{N}^0 = (\mathcal{N} \cap S^0)^0 = X^0$. □

The schemes $\mathcal{N}$ and $X$ are not necessarily smooth, i.e., their special fibers may not be reduced. To achieve the desired smooth NR-model $T$, one should apply the smoothening process (see [BLR, Chap. 3]). It is sufficient to control the defect of smoothness over $X = \mathcal{N} \cap S^0$ ([BLR, Prop. 10.1/4]). Thus the equality of the identity components of the two models is preserved. We denote the obtained smooth standard model by $X_{sm}$. As the ring representing $X$ is Noetherian, this process consists of blowing up finitely many maximal ideals and $X_{sm}$ remains of finite type. Moreover, by definition, the generic fibers of $X_{sm}$ and $X$ are isomorphic.

**Corollary 1.4.** $X^0_{sm} = T^0$. 4
2. Reductions and local volume computations

2.1. Rational points of the group of components. Denote by $i: \text{Spec } k \to \text{Spec } O_p$ the canonical closed immersion of the special point. We call the $k$-scheme $\Phi_T = i^*(T/T^0)$ the *group of components* of $T$. There is an exact sequence of $k$-schemes:

$$1 \to T^0_p \to T_p \to \Phi_T \to 1,$$

where $T_p = i^*(T)$ and $T^0_p = i^*(T^0)$. Let $l$ be the residue field of $L$ and let $g = \text{Gal}(l/k)$. Since $k$ is finite and $T^0_p$ is affine and connected, by Lang’s Theorem (see [Ser, Ch. VI, Prop. 5]), $H^1(g, T^0_p(l))$ is trivial implying the exactness of:

$$1 \to T^0_p(k) \to T_p(k) \xrightarrow{\phi} \Phi_T(k) \to 1. \quad (2.1)$$

Consider the map composition:

$$T(K) = T(O_p) \xrightarrow{r} T_p(k) \xrightarrow{\phi} \Phi_T(k)$$

where $r$ is the reduction modulo $p$ map and $\phi$ is the map in (2.1). As $T$ is smooth and $O_p$ is complete (and therefore henselian), $r$ is surjective (see [BLR, Prop. 2.3/5]). Since $\phi$ is also surjective and the kernel of $r \circ \phi$ is well-known to be $T^0(O_p)$ (see, e.g., [Gon, p. 1153]), we obtain:

**Lemma 2.1.** $T(K)/T^0(O_p) \cong T_p(k)/T^0_p(k) = \Phi_T(k)$.

The same construction for the smooth standard model $X_{\text{sm}}$ with its group of components $\phi_T = i^*(X_{\text{sm}}/X^0_{\text{sm}})$ leads to the corresponding isomorphism of abelian groups:

$$X_{\text{sm}}(O_p)/X^0_{\text{sm}}(O_p) \cong \phi_T(k). \quad (2.2)$$

**Lemma 2.2.** $X_{\text{sm}}(O_p)/T^0(O_p) \cong \phi_T(k) = \Phi_T(k)_{\text{tor}}$.

**Proof.** By Corollary 1.4, $X^0_{\text{sm}}(O_p) = T^0(O_p)$. Recall that $T$ is the smooth schematic closure $N_{\text{sm}}$ of $T$ in $S = R_{O_p}/O_p(T_L)$, whereas $X_{\text{sm}} = N_{\text{sm}} \cap S^0$ (see (1.2)). Thus as an abelian group:

$$T(O_p)/X_{\text{sm}}(O_p) \subseteq S(O_p)/S^0(O_p) \cong \Phi_R(k),$$

where $\Phi_R$ is the group of component of $R_{L/K}(\mathbb{G}_m^d)$ and it is free (see [Xar, Lem. 2.6]). We get a decomposition of abelian groups:

$$\Phi_T(k) \cong T(K)/T^0(O_p) \cong T(O_p)/X_{\text{sm}}(O_p) \times X_{\text{sm}}(O_p)/T^0(O_p)$$

on which the first factor is free and the second is finite (see Remark 1.1) and therefore is the torsion part of $\Phi_T(k)$. 

\[\square\]
2.2. local volume computations. As $K$ is locally compact, it admits a left invariant Haar measure. We normalize such an additive measure $dx$ on $K$ by requiring: $dx(p) = q^{-1}$, which is equivalent to $dx(\mathcal{O}_p) = 1$. This induces a multiplicative Haar measure $\omega_p$ on the group of points $T(K)$ (see [Weil, § 2.2]).

**Definition 2.** Let $M$ be one of the aforementioned $\mathcal{O}_p$-models of a $K$-torus $T$, namely the (smooth) standard model or the NR one. We call the reduction of $M$ “good” if $M'_p$ is a $k$-torus. As the identity components of these two models coincide, the definition of good reduction does not depend on the choice of a model.

**Proposition 2.3.** ([NX, Prop. 1.1]) A $K$-torus $T$ has good reduction if and only if it splits over an unramified extension. This means that $I$ acts trivially on $X^\bullet(T)$.

**Remark 2.4.** ([NX, Prop. 1.2]) Let $Y$ and $N$ be the kernel and image of the map 

$$tr : X^\bullet(T) \to X^\bullet(T)^I, \; \chi \mapsto \sum_{\sigma \in I} \chi^\sigma.$$ 

Then the exact sequence:

$$0 \to Y \to X^\bullet(T) \to N \to 0$$

induces an exact sequence of $K$-tori:

$$1 \to T_I \to T \to T_a \to 1 \tag{2.3}$$

on which $T_I$ is the maximal subtorus of $T$ having good reduction whereas $T_a$ is $I$-anisotropic, i.e. $X^\bullet(T_a)^I = \{0\}$, standing extremely on the other edge with regard to the good reduction one.

Sequence (2.3) shows that any torus is an extension of such two pieces.

**Remark 2.5.** [NX, Thm. 1.3] Let $T(p)$ be the toric part of $T'_p$. There is an isomorphism of $\Gamma/I$-modules:

$$X^\bullet(T(p)) \cong X^\bullet(T_I) \cong X^\bullet(T)/\ker(X^\bullet(T) \xrightarrow{tr} X^\bullet(T)^I).$$

**Remark 2.6.** A $K$-torus $T$ admits a finite type NR-model $T$ if and only if $T \otimes_K K^{sh}$ does not contain any subgroup of type $\mathbb{G}_m$ (see [BLR, 10.2.1]), i.e., it is $I$-anisotropic. In this case $T$ coincides with the smooth standard model $X_{sm}$ (see [Pop, Prop. 10.8]).

We briefly introduce now the local Artin functions which serve as a system of convergence factors in the infinite product of local measures on the global Shyr invariant (see formula (0.1)).

The following definitions can be found in [Vos, § 13] and in [Neu, Chap. VII, § 10.1]. The Galois group of the maximal unramified subextension in $L/K$, namely $\Gamma/I$, is isomorphic to $\mathfrak{g} = Gal(l/k)$.
and is generated by the Frobenius automorphism $F$. $g$ acts naturally on $X^\bullet(T)^I$, inducing an integral representation:

$$h : g \to Aut(X^\bullet(T)^I) \cong GL_{d_I}(\mathbb{Z}), \quad d_I = \text{rank}(X^\bullet(T)^I).$$

Denote the character of this representation by $\chi_T$.

**Definition 2.7.** The local Artin $L$-function for $T$ is defined by

$$L_p(s, \chi_T, L/K) = L_p(s, \chi_T) = \det \left( 1 - \frac{h(F)}{q^s} \right)^{-1},$$

where $s \in \mathbb{C}$ with $\text{Re}(s) > 1$.

**Theorem 2.8.** ([Vos, Thm. 14.3/3])

If $T$ splits over an unramified extension then:

$$|T(k)| \cdot q^{-d} = L_p(1, \chi_T)^{-1}, \quad d = \text{dim } T.$$  

**Definition 2.9.** Let $G_1, G_2$ be algebraic groups defined over a field $K$. An isogeny $\lambda : G_1 \to G_2$ is a surjective homomorphism of algebraic groups with finite kernel. We denote it by $\lambda : G_1 \equiv G_2$.

**Theorem 2.10.** ([Xar, 2.19]) Let $T$ be an algebraic torus defined over a local field $K$ splitting over a Galois extension $L$ with inertia subgroup $I$. $\Phi_T$ is torsion-free if and only if $H^1(I, X^\bullet(T)) = 0$.

As one can observe from Theorem 2.10, the abelian group $H^1(I, X^\bullet(T))$ which is isomorphic by Tate-duality to $H^1(I, T)$, measures the lack of connectedness of the torsion part in $\Phi_T(k)$. As this property is not invariant under isogeny, according to Corollary 2.2, this prevents at the same time the Shyr invariant to be respected by an isogeny of tori.

**Proposition 2.11.** ([Ono, §1.3.1]) Let $K$ be any field and $L$ be a finite Galois extension with $\Gamma = Gal(L/K)$. Let $T^*, T \in C(L/K)$. Then:

$$T^* \equiv T \iff X^\bullet(T^*) \otimes \mathbb{Q} \cong X^\bullet(T) \otimes \mathbb{Q} \text{ as } \Gamma\text{-modules.}$$

**Lemma 2.12.** Let $T^*, T$ be $K$-isogenous tori. Then the toric parts of their reductions are $k$-isogenous.

**Proof.** Consider the two exact sequence of $\Gamma$-modules for $T$ and $T^*$, induced by the canonical decomposition (2.3). Since $\mathbb{Q}$ is flat as a $\mathbb{Z}$-module, exactness is preserved after tensoring with it:

$$0 \to X^\bullet(T_a) \otimes \mathbb{Q} \to X^\bullet(T) \otimes \mathbb{Q} \to X^\bullet(T_I) \otimes \mathbb{Q} \to 0,$$

$$0 \to X^\bullet(T^*_a) \otimes \mathbb{Q} \to X^\bullet(T^*) \otimes \mathbb{Q} \to X^\bullet(T^*_I) \otimes \mathbb{Q} \to 0.$$
Recall from Theorem 2.5 that:

$$X^\bullet(T_I) \cong X^\bullet(T) / \ker(X^\bullet(T) \xrightarrow{tr} X^\bullet(T))$$.

As $T$ and $T^\ast$ are $K$-isogenous, according to Theorem 2.11, $X^\bullet(T) \otimes \mathbb{Q} \cong X^\bullet(T^\ast) \otimes \mathbb{Q}$ and therefore:

$$\ker(X^\bullet(T) \otimes \mathbb{Q} \xrightarrow{tr} X^\bullet(T)^I \otimes \mathbb{Q}) = \ker(X^\bullet(T^\ast) \otimes \mathbb{Q} \xrightarrow{tr} X^\bullet(T^\ast)^I \otimes \mathbb{Q})$$

implying that $X^\bullet(T_I) \otimes \mathbb{Q} \cong X^\bullet(T_I^\ast) \otimes \mathbb{Q}$. By Remark (2.5) this is equivalent to an isomorphism of their reduction toric part as $g = \text{Gal}(l/k)$-modules:

$$X^\bullet(T^\ast_{(p)}) \otimes \mathbb{Q} \cong X^\bullet(T_{(p)}) \otimes \mathbb{Q},$$

which again by Proposition 2.11 implies that $T^\ast_{(p)}$ and $T_{(p)}$ are $k$-isogenous. \hfill \Box

We consider another good reduction torus associated to $T$, namely, the factor torus $T^I$ corresponding to the $\Gamma$-module $X^\bullet(T)^I$.

**Lemma 2.13.** $T_I$ and $T^I$ are $K$-isogenous.

**Proof.** Consider again the canonical decomposition of $\Gamma$-modules (2.4):

$$0 \rightarrow X^\bullet(T_a) \rightarrow X^\bullet(T) \xrightarrow{tr} X^\bullet(T_I) \rightarrow 0.$$

Taking the $I$-invariants gives the long exact sequence:

$$0 \rightarrow X^\bullet(T_a)^I = 0 \rightarrow X^\bullet(T)^I \rightarrow X^\bullet(T_I)^I = X^\bullet(T_I) \rightarrow H^1(I, T_a).$$

The finiteness of $H^1(I, T_a)$ implies the one of $\text{coker}(X^\bullet(T)^I \rightarrow X^\bullet(T_I))$, which means that the $\mathbb{Z}$-lattice $X^\bullet(T)^I$ is a sublattice of finite index in the $\mathbb{Z}$-lattice $X^\bullet(T_I)$. Back to $K$-tori, this indicates that the corresponding epimorphism $T_I \rightarrow T^I$ has a finite kernel. \hfill \Box

**Proposition 2.14.** $\omega_p(T^0(\mathcal{O}_p)) = |T^0_{(p)}(k)| \cdot q^{-d} = L_p(1, \chi_T)^{-1}$.

**Proof.** $T^0$ is the reduction preimage of the $k$-group $T^0_{(p)}$, thus it is smooth and therefore the reduction of points $T^0(\mathcal{O}_p) \rightarrow T^0_{(p)}(k)$ is surjective. Consider the exact sequence:

$$1 \rightarrow T^1(\mathcal{O}_p) \rightarrow T^0(\mathcal{O}_p) \rightarrow T^0_{(p)}(k) \rightarrow 1. \quad (2.4)$$

The reduction image of $T^1(\mathcal{O}_p)$ is the $d$-tuple $(1, ..., 1)$ in $T^0_{(p)}(k)$ where $d = \dim T^0 = \dim T$. It is isomorphic to another preimage of this map, namely $(1 + p)^d$, which is homeomorphic to the additive group $p^d$ implying that $\omega_p(T^1(\mathcal{O}_p)) = \bigwedge_{i=1}^d dx_i(p^d) = q^{-d}$ and consequently by (2.4):

$$\omega_p(T^0(\mathcal{O}_p)) = |T^0_{(p)}(k)| \cdot q^{-d}. $$
As for the right hand equality of the Proposition, $T^0_p$ is an affine smooth and connected $k$-group (see [NX, §1]). It has a canonical decomposition over $k$: 

$$T^0_p = T(\mathcal{O}) \times U$$

where $T(\mathcal{O})$ is a $k$-torus and $U$ is a unipotent $k$-group. $U$ is isomorphic to an affine space $A_{\dim U}$ thus $|U(\mathcal{O})| = q^{\dim U}$ and the canonical decomposition over $k$:

$$T^0_p \mid q^{-d_I} T(\mathcal{O})^*$$

where $d_I = \dim T(\mathcal{O})$. Let $T_I$ be the maximal subtorus of $T$ with good reduction. From Remark 2.5, $X(T_I) \cong X(T(p))$ as $\Gamma/I$-modules. Thus we may deduce that $T(\mathcal{O})$ is equal to $L_p(1, \chi_{T_I})$. According to Lemma 2.13, $T_I$ and $T_{I'}$ are $K$-isogenous. These tori have good reduction, thus due to Lemma 2.12 their reductions (being $k$-tori) are $k$-isogenous, implying that their $L$-functions coincide (see [Vos, p. 106]). In particular $L_p(1, \chi_{T_I})$ is equal to $L_p(1, \chi_{T_I})$ which is by definition equal to $L_p(1, \chi_{T})$. □

As noted in Remark 1.1, $X(\mathcal{O})$ is the maximal compact subgroup of $T(K)$. Further, it is equal to $X_{\text{sm}}(\mathcal{O})$ (see [BLR, §3.1 Def. 1]). From Lemmas 2.2 and 2.14 the local component in the Shyr invariant can be computed by:

**Corollary 2.15.** $L_p(1, \chi_{T}) \cdot \omega_p(X_{\text{sm}}(\mathcal{O})) = (X_{\text{sm}}(\mathcal{O}) : T(\mathcal{O})) = |\Phi_{T, \text{tor}}|$.

3. **Relation with the cocharacter group**

The following construction can be found in [Ko, §7.2]. It was originally defined over a $p$-adic field but as we shall see, it can be applied also in case (F). Let $K^{\text{sh}}$ be the strict henselization of the local field $K$ in a separable closure $K_s$. As $K^{\text{sh}}$ is the maximal unramified extension of $K$, the group $Gal(K_{s}/K^{\text{sh}})$ is the inertia subgroup $I$ of the absolute one $Gal(K_{s}/K)$. R. Kottwitz extends the canonical epimorphism $(K^{\text{sh}})^{\times} \rightarrow \mathbb{Z}$ with kernel equal to the group of units of $K^{\text{sh}}$, to an epimorphism

$$K_T : T(K^{\text{sh}}) \rightarrow X_{\text{sm}}(T)_{I}$$

where the latter group is the $I$-coinvariants of the cocharacter group. Let $T$ be the NR-model of $T$ defined over the ring of integers $\mathcal{O}_{p}^{\text{sh}}$ of $K^{\text{sh}}$.

**Lemma 3.1.** $\ker(K_T) = T(\mathcal{O}_p^{\text{sh}})$.

**Proof.** As noted in the first line of the proof of [HR, Prop. 3, p.189], $\ker(K_T)$ is the unique Iwahori subgroup of $T(K^{\text{sh}})$. Thus, by [HR], Definition 1, p.188, and the statement of the cited proposition,
ker(\mathcal{K}_T) coincides with \mathcal{T}^0(\mathcal{O}_p^{sh}) (see [RP, Remarks 2.2.(iii)]). Note that the proof applies to any strictly henselian discretely-valued field and therefore covers both cases (N) and (F).

Since the residue field of \mathcal{K}^{sh} is \mathbb{k}_s, the group of components of \mathcal{T} splits over it, i.e. \Phi_T(k_s) = \Phi_T. Hence together with Lemma 2.1, the Kottwitz construction gives rise to an isomorphism

$$T(\mathcal{K}^{sh})/\mathcal{T}^0(\mathcal{O}_p^{sh}) \cong \Phi_T \cong X_\bullet(T)_I.$$ (3.1)

Now let \mathcal{T} be defined over \mathcal{K} and let \mathcal{T} be its NR-model. The absolute group \mathfrak{g}_{sep} = Gal(k_s/k) being generated by the Frobenius automorphism \mathcal{F}, is identified with \Gamma^{sh} = Gal(\mathcal{K}^{sh}/\mathcal{K}) . The scheme \mathcal{T}^0 has a geometrically connected fiber. Moreover, it is affine over \mathcal{O}_p (see [KM, Prop. 3] and [BLR, p. 290]). Thus by Lang’s Theorem, the cohomology group

$$H^1(\langle \mathcal{F} \rangle , \mathcal{T}^0(\mathcal{O}_p^{sh})) = H^1(\langle \mathcal{F} \rangle , \mathcal{T}^0(k_s))$$

where \mathbb{k} is considered as an \mathcal{O}_p-algebra, is trivial. Hence taking the \Gamma^{sh}-invariants of (3.1) gives rise to an epimorphism (see [Ko, 7.6.2]):

$$T(\mathcal{K}) \to (X_\bullet(T)_I)^{\langle \mathcal{F} \rangle}$$

with kernel equals to \mathcal{T}^0(\mathcal{O}_p^{sh}) \cap T(\mathcal{K}) = \mathcal{T}^0(\mathcal{O}_p) . Again by Lemma 2.1 and Corollary 2.15 we get:

**Corollary 3.2.**

$$T(\mathcal{K})/\mathcal{T}^0(\mathcal{O}_p) \cong \Phi_T(k) \cong \ker(1 - \mathcal{F}|X_\bullet(T)_I).$$

and:

$$X_{sm}(\mathcal{O}_p)/\mathcal{T}^0(\mathcal{O}_p) \cong \Phi_T(k)_{tor} \cong \ker(1 - \mathcal{F}|X_\bullet(T)_I)_{tor}.$$  

**Example 3.3.** Let \mathcal{L} be a cyclic extension of \mathcal{K} with Galois group \Gamma = \langle \sigma \rangle . Let \mathcal{R} = R_{L/K}(\mathbb{G}_m) be the corresponding Weil torus, i.e., such that for any \mathcal{K}-algebra \mathcal{B} , \mathcal{R}(\mathcal{B}) = (\mathcal{B} \otimes \mathcal{L})^{\times} . The norm torus \mathcal{T}' = R_{L/K}^{(1)}(\mathbb{G}_m) is the kernel of the norm map \mathbb{N}_{L/K} : \mathcal{R} \to \mathbb{G}_{m,K} , mapping any element of \mathcal{R}(\mathcal{B}) to the product of its images under all Galois automorphisms. Suppose \mathcal{L}/\mathcal{K} is totally ramified, i.e., \mathcal{I} = \Gamma . Then \mathcal{T}' is an \mathcal{I}-anisotropic torus. Its NR-model \mathcal{T}' which is of finite type, coincides with the smooth standard one \mathcal{X}'_{sm} (see Remark 2.6). Note that the character group \mathcal{X}_\bullet(\mathcal{R}) = \mathbb{Z}[\Gamma] (see [Vos, §3.12]), coincides as a \Gamma-module with the group of cocharacters:

$$\mathcal{X}_\bullet(\mathcal{R}) = \text{Hom}(\mathbb{G}_m, \mathcal{R} \otimes \mathcal{L}) = \text{Hom}(\mathbb{Z}, \mathbb{Z}[\Gamma]) = \mathbb{Z}[\Gamma] = \mathcal{X}_\bullet(\mathcal{R}).$$

Since \Gamma is cyclic, \mathcal{T} is isomorphic as a \Gamma-module to the projective group \mathcal{P} = \mathcal{R}/\mathbb{G}_m (see [LL, p. 22]). The exact sequences of \mathcal{K}-tori:

$$1 \to \mathcal{T}' \to \mathcal{R} \to \mathbb{G}_m \to 1$$
1 \rightarrow \mathbb{G}_m \rightarrow R \rightarrow P \rightarrow 1

induce the exact sequences of dual modules:

\[0 \rightarrow \mathbb{Z} \rightarrow X^*(R) \rightarrow X^*(T') \rightarrow 0\]
\[0 \rightarrow \mathbb{Z} \rightarrow X_*(R) \rightarrow X_*(P) \rightarrow 0.\]

We get an isomorphism of \(\Gamma\)-modules: 
\[X_*(T') \cong X_*(P) \cong X^*(T').\]
Explicitly we have 
\[X'_{\text{sm}}(\mathcal{O}_p)/T^0(\mathcal{O}_p) \cong X_*(T')_{I} = \left(Z[\sigma]/\sum_{i} \sigma^i\right)/(1 - \sigma) = \mu_n\]

thus by Corollary 2.15 we get 
\[L_p(1, \chi_{T'}) \cdot \omega_p(X'_{\text{sm}}(\mathcal{O}_p)) = n.\]
More generally, for any extension \(L/K\), we have 
\[X'_{\text{sm}}(\mathcal{O}_p)/T^0(\mathcal{O}_p) \cong \phi_{T'} = \mu_e\] where \(e\) is the ramification index (see [Pop, Thm. 3]).

4. ONO AND SHYR INVARIANTS

In the following Section we briefly describe the analogues of the arithmetic invariants of number fields for algebraic tori as defined by Ono, and the analogue of the classical class number formula for algebraic \(\mathbb{Q}\)-tori, as formulated by Ono and Shyr. This construction is generalized to \(K\)-tori where \(K\) is any global field. Finally, our local results will be inserted in these invariant formulas.

4.1. Arithmetical invariants of algebraic tori.

**Notation 4.1.** Let \(K\) be a global field, i.e., either a number field or an algebraic function field in one variable over a finite field of constants \(\mathbb{F}_q\). We denote:
\[\Delta_K\] – the discriminant of \(K\). In case \((F)\) equals to \(q^{2g-2}\) where \(g\) is the genus of \(K\).
\(S\) – a finite set of valuations of \(K\) which contains the set \(S_{\infty}\) of the archimedean ones.
\(K_v\) – the completion of \(K\) with respect to a valuation \(v \in S\).
\(\mathcal{O}_v\) – the ring of integers of \(K_v\) and \(U_v = \mathcal{O}_v^\times\) – its subgroup of units.
\(T_v = T \otimes K_v\) and \(T_v(\mathcal{O}_v) = \{x \in T_v(K_v) : \chi(x) \in U_v \forall \chi \in X^*(T)_{K_v}\}\).

If \(v = p\) is a prime, \(T_p(\mathcal{O}_p)\) is the maximal compact subgroup of \(T_p(K_p)\), \(\mathfrak{P}\) is a prime of \(L\) lying over \(p\), \(\Gamma_p = Gal(L_{\mathfrak{P}}/K_p)\) and \(I_p\) is the inertia subgroup.

In Definition 2.7 we defined the local Artin \(L\)-function. Globally, consider the action of \(\Gamma\) on \(X^*(T)\) and the corresponding representation \(\Gamma \rightarrow Aut(X^*(T)) \cong GL_n(\mathbb{Z})\). Its character \(\chi_T\) is decomposed into a sum of irreducible characters of \(\Gamma\) with integral coefficients:
\[\chi_T = \sum_{i=1}^{m} a_i \chi_i, \ a_i \in \mathbb{Z}\]
where $\chi_1$ is the principal character.

The global Artin L-function is defined by the Euler product:

$$L(s, \chi_T) = L(s, \chi_T, L/K) = \prod_p L_p(s, \chi_{T_p}, L_{Q_p}/K_p)$$

again with $Re(s) > 1$, having a pole at $s = 1$ of order $a_1$.

**Definition 3.** The quasi-residue of $T$ is the limit:

$$\rho_T = \lim_{s \to 1} (s - 1)^{a_1} L(s, \chi_T).$$

Following Ono in [Ono], for any finite set of places $S$ which contains $S_\infty$ we define $T_A(S) = \prod_{v \in S} T_v \prod_{v \notin S} T_v(O_v)$. Then the adelic group $T_A$ is the inductive limit of $T_A(S)$ with respect to $S$. The group of $S$-units is $T_K(S) = T_K \cap T_A(S)$. The group of units of $T$ is then $T_K(S_\infty)$ where $S_\infty$ is the set of archimedean places, which are the elements of $\Gamma$ composed with the absolute norm $| \cdot |_\infty$.

**Theorem 4.2.** Shyr’s generalization of Dirichlet Unit Theorem - see [Shyr2]

The group $T_K(S)$ is a direct product of the finite group $T_K \cap T_A$ where: $T_A = \prod_v T_v(O_v)$ and a group isomorphic to $\mathbb{Z}^{r(S)-r}$ where: $r(S) = \sum_{v \in S} r_v$.

Let $T$ be a $\mathbb{Q}$-torus and let $r_Q = \text{rank}(X^*(T)_Q)$, $r_\infty = \text{rank}(X^*(T)_\mathbb{R})$. Let $\{\xi_i\}_{i=1}^{r_\infty}$ be a $\mathbb{Z}$-basis of $X^*(T)_\mathbb{R}$ such that $\{\xi_i\}_{i=1}^{r_Q}$ is a $\mathbb{Z}$-basis of $X^*(T)_Q$. Then the group of units $T_K(S_\infty)$ is decomposed into $W \times E$ where $W$ is finite and $E \cong \mathbb{Z}^{r_\infty-r_Q}$. We denote $w_T = |W|$.

**Definition 4.** Let $\{e_j\}_{j=r_Q+1}^{r_\infty}$ be a $\mathbb{Z}$-basis of $E$. The number $R_T = |\det(\text{ln}|\xi_i(e_j)|_{r_Q+1 \leq j \leq r_\infty})|$ is called the regulator of $T$ over $\mathbb{Q}$. Geometrically, this number represents (as for number fields) the volume of the fundamental domain for the free part of group of units.

We set: $T_A^1 = \{x \in T_A : \chi(x) \in I_K^1 \forall \chi \in X^*(T)_K\}$ where $I_K^1 = \{a \in I_K : ||a|| = 1\}$ and $I_K$ denotes the idele group. It is the maximal subgroup of $T(A_K)$ such that $T_A^1/T(K)$ is compact.

**Definition 5.** The class number of $T$ is the finite index:

$$h_T = \begin{cases} [T_A : T_K \cdot T_A^{S_\infty}] & \text{case (N)} \\ [T_A^1 : T_K \cdot T_A^{S_\infty}] & \text{case (F)} \end{cases}$$

The global measure is obtained by the infinite product of these local measures, multiplied by a set of convergence local factors, namely, the Artin local $L$-functions $L_p(1, \chi_T)$:

$$\tau = \rho_T^{-1} |\Delta_K|^{-\frac{d}{2}} \prod_{v | \infty} \omega_v \prod_p L_p(1, \chi_T) \omega_p$$
This is called the *Tamagawa measure*. This measure applied to $\prod_p T_p(O_p)$ is convergent – almost all primes are unramified on which $L_p(1, \chi_T) \cdot \omega_p(T_p(O_p)) = 1$.

4.2. The quasi-discriminant definition. The geometrical meaning of a global field discriminant is the volume of a fundamental domain of its ring of integers. An analogue for the case of an algebraic torus $T$ defined over a global field, called the “quasi-discriminant” of $T$, is the volume – with respect to some normalized Haar measure – of the fundamental domain of the maximal compact subgroup of $T(A_K)/T(K)$. In the next Section we refer to two similar analogues, given by T. Ono and J. M. Shyr, to this invariant in the case of algebraic tori.

4.2.1. Ono’s invariant. The following construction can be found in [Ono]. Let $\{\chi_i\}_{i=1}^{r_K}$ be a $\mathbb{Z}$-basis of $X^\bullet(T)_K$. Consider the epimorphism $\psi : T_A \rightarrow \mathbb{R}_{+}^{r_K}$ defined by $\alpha \mapsto (\ln |\chi_i(\alpha)|)_{1 \leq i \leq r_K}$.

It yields the isomorphism $T_A/T_A^1 \cong \mathbb{R}_{+}^{r_K}$. For a Haar measure $d$ defined on $T_A$, consider the decomposition $d(T_A/T_K) = d(T_A/T_A^1) \cdot d(T_A^1/T_K)$. Let $t_K$ be the pullback of the Haar measure $dx_1 \cdots dx_{r_\infty}$ on $\mathbb{R}_{+}^{r_\infty}$ from $T_A/T_A^1$. Define the normalized Haar measure $\Omega_T$ on $T_A$, i.e., such that $\int_{T_A^1/T_K} d(\Omega_T/t_K) = 1$.

**Definition 6.** Comparing the measure $\Omega_T/t_K$ with the Tamagawa measure gives the constant

$$c_T^{Ono} = \frac{\omega_T}{\Omega_T/d_K}.$$

Now assume $K = \mathbb{Q}$. Let $\{\xi_i\}_{i=1}^{r_\infty}$ be a $\mathbb{Z}$-basis of $X^\bullet(T)_\mathbb{R}$ such that $\{\xi_i\}_{i=1}^{r_Q}$ is a $\mathbb{Z}$-basis of $X^\bullet(T)_\mathbb{Q}$. Define $\Phi_0 : T_\mathbb{R} \rightarrow \mathbb{R}^{r_\infty}$ by

$$x \mapsto (\ln |\xi_i(x)|)_{1 \leq i \leq r_\infty}.$$

By the unit Theorem, rank$(U) = r_\infty - r$. Let $\{e_j\}_{j=r_Q+1}^{r_\infty}$ be a $\mathbb{Z}$-basis of $E$ and consider the parallelotope:

$$P_0 = \left\{ \sum_{j=r_Q+1}^{r_\infty} \lambda_j \Phi_0(e_j) : 0 \leq \lambda_j \leq 1 \right\}.$$

This is the fundamental domain of $E$ on $\mathbb{R}^{r_\infty-r_Q}$ and its Euclidean volume is the regulator $R_T$. This domain may be extended to dimension $r_\infty$ by the cube $(1 \leq \lambda_j \leq e)_{1 \leq j \leq r_Q}$. The extended embedding $\Phi : T_A^{S_\infty} \rightarrow \mathbb{R}^{r_\infty}$ defined by $\Phi(x) = \Phi_0(x_\infty)$ (ignoring the non-archimedean places components), gives rise to a parallelotope $P$ by a continuation of a unit cube on $\mathbb{R}^{r_\infty}$. Thus the Euclidean volume of $P$ on $\mathbb{R}^{r_\infty}$ remains $R_T$. 

13
Lemma 4.3. ([Ono, 3.8.5]) \( \int_{\Phi^{-1}(P)} d(\Omega_T/t_Q) = w_T/h_T. \)

Denote by \( I \) the unit cube in \( \mathbb{R}^{r_\infty} \). Define by \( M_\infty \) the \( \infty \) component of \( \Phi^{-1}(I) \), i.e.,

\[
M_\infty = \{ x \in T_\mathbb{R} : 1 \leq |\xi_i(x)|_\infty \leq e, \ 1 \leq i \leq r_\infty \}.
\]

The regulator, being the Euclidean volume of \( P \) on \( \mathbb{R}^{r_\infty} \), is obtained by

\[
\frac{\int_{\Phi^{-1}(P)} d(\Omega_T/t_Q)}{\int_{\Phi^{-1}(I)} d(\Omega_T/t_Q)}
\]

hence we get

\[
e^{Ono}_T = \frac{\omega_T}{\Omega_T/t_K}(\Phi^{-1}(P)) = \frac{R_T \omega_T(\Phi^{-1}(I))}{\Omega_T/t_K(\Phi^{-1}(P))} = \frac{R_T \int_{M_\infty} \omega_\infty \prod_p L_p(1, \chi_T) \omega_p}{w_T/h_T}
\]

According to Theorem 4.2, the group of units of \( T \) defined over any number field \( K \) has a decomposition \( T_\mathbb{Z} \cong W \times E \) on which the group \( E \) is isomorphic to \( \mathbb{Z}^{r_\infty-r_K} \) and \( |W| = w_T. \) Hence Ono’s result can be generalized to an algebraic torus defined over any number field \( K \), by including the discriminant which is different from 1 in the general case. Recall that

\[
\omega_T = |\Delta_k|^{-d/2} \omega_\infty \prod_p L_p(1, \chi_T) \omega_p.
\]

Hence

\[
e^{Ono}_T = \frac{\omega_T}{\Omega_T/t_K(\Phi^{-1}(P))} = \frac{R_T |\Delta_k|^{-d/2} \int_{M_\infty} \omega_\infty \prod_p L_p(1, \chi_T) \omega_p}{w_T/h_T} \tag{4.1}
\]

Remark 4.4. This generalization is not required in case (F) on which the group of units of \( T \) has no free part, and thus has no regulator. Indeed, Ono’s result in that case is not restricted to \( F_\mathbb{Q}(x) \) being the analogue of \( \mathbb{Q} \), and Ono’s formula does include the discriminant there. We will write this formula explicitly in Section (5).

4.2.2. Shyr’s invariant. J. M. Shyr in [Shyr1] gave a similar definition to the one of Ono in the case of algebraic \( \mathbb{Q} \)-tori. Consider the decomposition of a local measure \( d \) into \( dT_v(K_v) = d(T_v(K_v)/T_v(O_v)) \cdot dT_v(O_v) \). The measure \( \nu_v \) is defined by the pullback of the measure \( \frac{dx_1 \cdots dx_v}{x_1^e \cdots x_v^e} \) on \( \mathbb{R}^{r_v}_+ \) (and the canonical discrete measure on \( \mathbb{Z}^{r_v}_+ \), respectively) for \( T_v(K_v)/T_v(O_v) \), matched together with the normalized Haar measure on \( T_v(O_v) \). Then the measure \( \nu_T \) is defined by the infinite product \( \prod_v \nu_v \) and \( \nu_T(T_A/T_K) = \nu_T(T_A/T_K) \). In this new construction, the other arithmetic invariants
are taken from Ono’s definition. Explicitly global Shyr invariant is computed by:

$$c_{T}^{Shyr} = \int_{M_{\infty}} \omega_{\infty} \prod_{p} \int_{T_{p}(O_{p})} L_{p}(1, \chi_{T}) \omega_{p}. $$

Shyr obtained a relation between the Haar measures: $\tau_{T} = \rho_{T}^{-1} c_{T}^{Shyr} \nu_{T}$. This led him to a formula reflecting the relation between the other arithmetic invariants of $T$ which can be viewed as a torus analogue of the class number formula, namely:

$$c_{T}^{Shyr} = \rho_{T} \tau_{T} \omega_{T}. $$

(4.2)

As we have done in (4.1), due to the generalization of the unit Theorem, this result can be generalized to an algebraic torus $T$ defined over any number field $K$ on which the field discriminant may not be 1. In that general case we would get

$$c_{T}^{Shyr} = \omega_{T}(\Phi^{-1}(I)) = |\Delta_{K}|^{-d/2} \int_{M_{\infty}} \omega_{\infty} \prod_{p} \int_{T_{p}(O_{p})} L_{p}(1, \chi_{T}) \omega_{p}. $$

(4.3)

The number $D_{T} = 1/(c_{T}^{Shyr})^{2}$ is called the quasi-discriminant of $T$ over $K$.

4.3. Main Theorem. With the above notations, using our previous local results, namely, Corollaries 2.15 and 3.2, we now get to the following computation of the Shyr invariant as appears in (4.3) with the relation in (4.2).

**Theorem 4.5.** For any prime $p$ of $K$, let $F_{p}$ be the local Frobenius automorphism, let $X_{\bullet}(T_{p})$ be the cocharacter group of $T_{p} = T \otimes K_{p}$ and let $X_{\bullet}(T_{p})_{I_{p}}$ be its coinvariants factor group. Then:

$$c_{T}^{Shyr} = |\Delta_{K}|^{-d/2} C_{\infty} \prod_{p} |\ker(1 - F_{p}|X_{\bullet}(T_{p})_{I_{p}})|_{tor} = \frac{\rho_{T} \tau_{T}^{w_{T}}}{h_{T}R_{T}}. $$

where

$$C_{\infty} = \begin{cases} \int_{M_{\infty}} \omega_{\infty} & \text{case}(N) \\ (\ln q)^{-r_{K}} & \text{case}(F) \end{cases} $$

and $\Delta_{K} = q^{2g-2}$, $R_{T} = 1$ in case(F).

5. Appendix: Tori defined over algebraic function fields

Let $X$ be a smooth, projective and irreducible algebraic curve of genus $g$ defined over $\mathbb{F}_{q}$ and let $Y$ be a finite Galois cover of $X$. Let $K = \mathbb{F}_{q}(X)$ and $L = \mathbb{F}_{q}(Y)$ be the corresponding fields of rational functions. Then $L/K$ is a finite Galois extension with $\Gamma = Gal(L/K)$. Let $T \in C(L/K)$ be an algebraic torus of dimension $d$.

Just as for number fields, let $\omega_{p}$ be a normalized invariant form on $K_{p}$, i.e., such that $\omega_{p}(O_{p}) = 1$. Since $\deg p = (O_{p}/p : \mathbb{F}_{q})$, we have $|O_{p}/p| = q^{\deg p}$. Hence the normalization condition implies
\( \omega_p(p) = q^{-\deg p} \). The infinite product \( \prod_p \omega_p \) which is multiplied by the set \( L_p(1, \chi_T, L/K) \) as a system of correcting factors, induces the Tamagawa measure on \( T \) (see [Weil, § 2.2]):

\[
\omega_T = q^{-(g-1)d} \prod_p L_p(1, \chi_T) \omega_p, \quad d = \dim T.
\]

Define the normalized measure \( \Omega_T \) on \( TA \) by the condition \( \int_{TA/T_K} d\Omega_T = 1 \). Then \( \omega_T = (\ln q)^{rK} c^O_{T,T} \Omega_T \), reflecting the decomposition

\[
d(TA/T_K) = d(TA/TA) \cdot d(TA/TK)
\]
on which \( TA/TA \) is given the measure \( (\ln q)^{rK} \) (see [Ono, § 3.2]). Hence in this case we get the relation:

\[
\tau_T = \frac{c^O_{T,T}}{\omega_T} = \frac{h_T \prod_p \int_{T_p(O_p)} L_p(1, \chi_T) \omega_p}{w_T \rho_T (\ln q)^{rK} q^{d(g-1)}}.
\] (5.1)

As in Shyr’s approach, consider the decomposition

\[
TA/T_K \cong (TA/TA) \times \left(TA/TKA^S \times T_K^S\right) \times \left(TA^S / TKA^S / T_K^S / W\right).
\]

Now, as we gave the measure \( (\ln q)^{rK} \) to each point in \( TA/TA \), we get

\[
\rho_T^{-1} \omega_T(TA/T_K) = \tau_T \cdot \frac{\mu_T(TA/T_K)}{(\ln q)^{rK}}.
\]

Thus over \( TA/T_K \) we have \( \rho_T^{-1} \omega_T \cdot (\ln q)^{rK} = \tau_T \mu_T \).

Since here there are no archimedean places, we have \( T^S_A = \prod_p T_p(O_p) = T^1_A^S \).

Now \( h_T = (TA/TA^S) TKA^S / T_K^S \) and \( TKA^S / T_K^S \cong T^S_A / W \) where \( W \) is finite.

Thus \( c_{TA}^{Shyr} = \frac{\omega_T}{\nu_T}(T^S_A) \). But: \( T^S_A \subset TA \) and so: \( \nu_T(TKA^S) = 1 \). Hence

\[
\frac{c_{TA}^{Shyr}}{\nu_T} = \frac{\omega_T}{\nu_T}(T^S_A) = \frac{(\ln q)^{-rK}}{q^{d(g-1)}} \prod_p L_p(1, \chi_T) \omega_p(T_p(O_p)).
\] (5.2)

From the equation above \( \tau_T = \rho_T^{-1} c_{TA}^{Shyr} \), we get the following relation, which can be viewed as a class number formula analogue for algebraic tori defined over function fields:

\[
\frac{c_{TA}^{Shyr}}{\nu_T} = \frac{\omega_T}{\nu_T}(T^S_A) = \rho_T \tau_T \mu_T (T^S_A) = \frac{\rho_T \tau_T \nu_T}{h_T}.
\] (5.3)

Note that this result is none other than formula (5.1) obtained by T. Ono (see [Ono, 3.8.10’]).
