Reconstitution of a 26-Subunit Human Kinetochore Reveals Cooperative Microtubule Binding by CENP-OPQRUR and NDC80

Highlights

- The kinetochore CENP-OPQR complex is reconstituted and functionally dissected
- A kinetochore particle with 26 subunits and defined stoichiometry is reconstituted
- EM structure of an 11-subunit inner kinetochore complex reveals globular shape
- CENP-Q and the Ndc80 complex bind microtubules cooperatively

In Brief
Kinetochores mediate chromosome attachment to the mitotic spindle. In a biochemical tour-de-force, Pesenti et al. reconstituted a 26-subunit kinetochore particle and characterized its structural organization. The CENP-Q subunit was shown to increase the microtubule-binding affinity of kinetochores, revealing that the kinetochore-spindle interaction is more complex than hitherto believed.
Reconstitution of a 26-Subunit Human Kinetochore Reveals Cooperative Microtubule Binding by CENP-OPQUR and NDC80

SUMMARY

The approximately thirty core subunits of kinetochores assemble on centromeric chromatin containing the histone H3 variant CENP-A and connect chromosomes with spindle microtubules. The chromatin proximal 16-subunit CCAN (constitutive centromere associated network) creates a mechanically stable bridge between CENP-A and the kinetochore's microtubule-binding machinery, the 10-subunit KMN assembly. Here, we reconstituted a stoichiometric 11-subunit human CCAN core that forms when the CENP-OPQUR complex binds to a joint interface on the CENP-HIKM and CENP-LN complexes. The resulting CCAN particle is globular and connects KMN and CENP-A in a 26-subunit recombinant particle. The disordered, basic N-terminal tail of CENP-Q binds microtubules and promotes accurate chromosome alignment, cooperating with KMN in microtubule binding. The N-terminal basic tail of the NDC80 complex, the microtubule-binding subunit of KMN, can functionally replace the CENP-Q tail. Our work dissects the connectivity and architecture of CCAN and reveals unexpected functional similarities between CENP-OPQUR and the NDC80 complex.

INTRODUCTION

Accurate chromosome segregation in mitosis and meiosis is of paramount importance for cellular and organismal viability. The ultimate goal of chromosome segregation is to endow the two daughter cells with a full complement of chromosomes, preventing the considerable burdens associated with whole-chromosome aneuploidy (Santaguida and Amon, 2015). Chromosome segregation requires the establishment of a structure named the mitotic spindle, which consists of microtubules, microtubule-associated proteins, and motors that harness the energy of ATP hydrolysis to organize microtubules in dense antiparallel arrays and to focus them at the spindle poles (Heald and Khodjakov, 2015).

Crucial for the chromosome segregation process is the attachment of chromosomes to the mitotic spindle. This takes place at kinetochores, large protein complexes built on a stretch of specialized chromatin named the centromere (Pesenti et al., 2016). A conserved feature of centromeric chromatin is the presence of a histone H3 variant named centromeric protein A (CENP-A, or CenH3), which interacts with histones H4, H2A, and H2B in a specialized nucleosome particle. Original work with anti-centromere antibodies, and more recent proteomic analyses of CENP-A and its binding partners, identified 16 vertebrate proteins now collectively identified as the constitutive centromere-associated network (CCAN, Figure 1A), reflecting association of these proteins with kinetochores during the entire cell cycle (Earnshaw and Rothfield, 1985; Foltz et al., 2006; Hori et al., 2008a; Izuta et al., 2006; Obuse et al., 2004; Okada et al., 2006; Saitoh et al., 1992). These CCAN subunits are organized in distinct subcomplexes, including the CENP-T:CENP-W complex (herewith CENP-TW), proposed to form a nucleosome-like particle with CENP-S: CENP-X (CENP-SX) (Hori et al., 2008a; Nishino et al., 2012); the CENP-L:CENP-N (CENP-LN) complex (Carroll et al., 2009, 2010); the CENP-H:CENP-I:CENP-K:CENP-M (CENP-HIKM) complex (Basilico et al., 2014; Klare et al., 2015; Okada et al.,...
CENP-C, which based on sequence prediction methods is largely intrinsically disordered, may function as a spatial organizer of the CCAN, binding to the CENP-HIKM and CENP-LN complexes (Hinshaw and Harrison, 2013; Klare et al., 2015; McKinley et al., 2015; Nagpal et al., 2015; Pentakota et al., 2017; Weir et al., 2016). The resulting 7-subunit assembly (CENP-CHIKMLN) establishes multiple contacts with the CENP-A nucleosome through CENP-A-selective binding regions in CENP-C and CENP-N (Cao et al., 2018; Carroll et al., 2009, 2010; Chittori et al., 2018; Falk et al., 2016; Guo et al., 2017; Kato et al., 2013; Pentakota et al., 2017; Tian et al., 2018; Weir et al., 2016). Acting as bridge for the microtubule binding “outer kinetochore”, CCAN contributes also to the mechanical stability of kinetochores (Suzuki et al., 2014). The CENP-TW complex, which binds directly to CENP-CHIKMLN and requires it for kinetochore targeting, contributes to the recruitment of the KMN (KNL1, MIS12, NDC80) assembly (Huis In’t Veld et al., 2016; Kim and Yu, 2015; Malvezzi et al., 2013; Nishino et al., 2013; Pekgoz Altunkaya et al., 2016; Rago et al., 2015; Schleiffer et al., 2012). Within the KMN, the 4-subunit NDC80 complex (NDC80C) is considered the major microtubule receptor of the kinetochore (Cheeseman, 2014; Pesenti et al., 2016). The CENP-TW pathway coexists with, and depends on, a second axis of outer kinetochore assembly centered on CENP-C (for an extended discussion, see Huis In’t Veld et al., 2016 and Pesenti et al., 2016). Besides interacting with CCAN, CENP-C also binds directly to the KMN assembly (Gascoigne et al., 2011; Przewloka et al., 2011; Screpanti et al., 2011) (Figure 1A).

CENP-CHIKMLN is also required for recruitment of a 5-subunit complex incorporating the CENP-O, CENP-P, CENP-Q, CENP-U, and CENP-R subunits (CENP-OPUR, which has preformed contacts with CENP-CHIKMLN, and corresponds to the Chk19:Mcm21 complex (PDB ID 3ZXU), respectively homologous to CENP-P and CENP-O, was manually fitted in the head domain. The difference map between CENP-OPQU and CENP-OPUR, corresponding to the density of CENP-R, is shown in purple. See also Figure S1.
whose subunits are schematically shown in Figure 1B) (Eskat et al., 2012; Foltz et al., 2006; Hori et al., 2008b; McKinley et al., 2015; Minoshima et al., 2005; Okada et al., 2006; Samejima et al., 2015). CENP-OPQUR is related to the CCAN complex of S. cerevisiae (De Wulf et al., 2003; Hori et al., 2008b; Hyland et al., 1999; Ortiz et al., 1999; Schmitzberger et al., 2017; Westermann et al., 2003). Its precise role at kinetochores remains poorly characterized, but it consists at least in part in the recruitment of other kinetochore residents, including the microtubule plus-end directed motor CENP-E and Polo-like kinase 1 (Pik1), the latter through phosphorylation of CENP-U (Bancroft et al., 2015; Hori et al., 2008b; Kang et al., 2006). Microtubule-binding activities have also been independently attributed to CENP-Q or CENP-U (Amaro et al., 2010; Hua et al., 2011).

In an effort to reconstitute kinetochores in vitro, we recently reported the assembly, entirely from recombinant material, of a 21-subunit assembly containing the CENP-A nucleosome, the CENP-CHIKMLN complex, and the 10-subunit KMN network (Weir et al., 2016). Biochemical reconstitution is crucial for unraveling the organization of kinetochores, as it facilitates the identification of stable modules of subunits, and for the characterization of their physical interactions, stoichiometries, and regulation. Furthermore, biochemical reconstitution can provide material for detailed structural analyses and for in vitro measurements of kinetochore function (e.g., force generation) under controlled conditions. Thus, our ultimate goal is to be able to reconstitute kinetochore particles that encompass the majority, or all, of constitutive subunits.

Here, we report the reconstitution of most of the CCAN complex, its structural characterization, its interactions within the human kinetochore, and its contributions to microtubule binding. We find that CCAN forms a globular particle, the topology of which we describe in detail. We also significantly extend our understanding of the mechanism of microtubule binding by the CCAN and its relationship to the previously characterized microtubule-binding site in the KMN network. Our studies provide strong mechanistic and structural insights into a fundamental and conserved component of the chromosome segregation machinery.

RESULTS

Reconstitution and Structural Analysis of CENP-OPQUR

To investigate the requirements for stability of CENP-OPQUR subunits, we turned to in vitro reconstitution with recombinant components. CENP-O, -P, -Q, and -U were unstable when expressed individually in bacteria or insect cells and could not be recovered in soluble form (unpublished data). Co-expression in insect cells yielded two stable subcomplexes, CENP-OP and CENP-QU, which were purified to homogeneity and appeared monodisperse by size-exclusion chromatography (SEC; Figures 1C, S1A, and S1B). To generate the CENP-OPQUR complex, we mixed stoichiometric amounts of CENP-OP and CENP-QU (Figure S1C) or co-infected insect cells (see STAR Methods; Figure S1D). Sedimentation velocity analytical ultracentrifugation (AUC) demonstrated that CENP-OP, CENP-QU, and CENP-OPQU contained single copies of each subunit (Table S1; Figure S1E).

CENP-R was stable when expressed in isolation, appeared monodisperse by SEC, and formed tetramers in AUC experiments (Figures S1E and S1F; Table S1). However, it did not interact with CENP-OP, CENP-QU, or CENP-OPQU in SEC experiments (Figures S1G and S1H). Conversely, CENP-R interacted with CENP-OPQU when co-expressed or when cell pellets where lysed together (co-lysis). The CENP-OPQU complex, obtained by co-lysis, was monodisperse by SEC (Figure S1I), and AUC showed that it contained a single copy of each subunit (Figure S1E; Table S1). Thus, we suspect that CENP-R forms oligomers when it cannot interact in the CENP-OPQUR complex. This may not be an isolated case, because a previous study reported that CENP-Q, expressed and purified in isolation, forms octamers (Amaro et al., 2010). Our inability to obtain soluble CENP-Q in isolation prevented us from confirming this previous observation, but our results identify single copies of CENP-Q and CENP-R in the CENP-OPQUR complex. In co-expression experiments, we observed that CENP-R interacts predominantly with the CENP-QU subcomplex (Figure S1J).

Electroporated in interphase or mitotic HeLa cells, recombinant CENP-OPQUR covalently modified with Alexa488 fluorophore labeled kinetochores (marked by CREST auto-antibodies), indicating that the recombinant complex retains crucial properties of its endogenous counterpart (Figures 1D and S1K, representative of at least three independent experiments).

We studied the structural organization of the CENP-OPQUR and CENP-OPQUR complexes by negative-stain electron microscopy (EM) (Figures 1E–1H, S2A, and S2B). Three-dimensional (3D) reconstructions showed that the structure of CENP-OPQUR is bi-lobed, with a smaller head domain and a larger base domain. CENP-R did not grossly alter this organization, but an additional protuberance in the neck region and an enlargement in the base domain became evident (Figures 1G–1I).

Mechanism of Kinetochore Recruitment of the CENP-OPQUR Complex

Recently, we reconstituted a 7-subunit, CENP-A-associated CCAN subcomplex that includes CENP-C (and specifically its N-terminal region, residues 1–544: CENP-C1544), the 4-subunit CENP-HIKM complex (containing a truncated form of CENP-I lacking its 56 N-terminal residues, and henceforth indicated as CENP-I546), and the 2-subunit CENP-LN complex (Basilico et al., 2014; Klare et al., 2015; Weir et al., 2016). To assess the role of selected subunits of this CENP-A-associated complex (herewith referred to as CENP-CHIKMLN complex) in CENP-OPQUR recruitment, we created stable HeLa cell lines expressing, under an inducible promoter, each of the individual CENP-OPQUR subunits fused to green fluorescent protein (GFP), and we tested their kinetochore targeting in control cells and in cells depleted of CENP-H, CENP-L, or CENP-N by RNAi (Figures S2A–S2E). Each CENP-OPQUR subunit was lost from kinetochores under these conditions (shown in Figures 2A and 2B for CENP-Q and in Figures S2B–S2E for CENP-O, -P, -R, and -U).

Thus, CENP-A proximal subunits of CCAN are required for recruitment of CENP-OPQUR subunits, in agreement with previous observations (Eskat et al., 2012; Foltz et al., 2006; Hori et al., 2011; Hua et al., 2011; Minoshima et al., 2005; Okada et al., 2006; Samejima et al., 2015).
Figure 2. Molecular Basis of Kinetochore Recruitment of CENP-OPQR

(A) Depletion of CENP-H, CENP-L, or CENP-N prevented kinetochore localization of GFP-CENP-Q in HeLa FlpIn TRex cell lines stably expressing GFP-CENP-Q, as shown by representative images. CENP-HK complex is also lost from kinetochores during the aforementioned RNAi depletions. Scale bar, 5 μm.

(B) Quantification of the amount of GFP-CENP-Q (green bars) and CENP-HK (red bars) at kinetochores following CENP-H, CENP-L, or CENP-N depletion. **p < 0.01. Graph shows representative results from one of three independent experiments. A minimum of 158 kinetochores was quantified.

(C) Coomassie-stained SDS-PAGE of recombinant CENP-C1–544, CENP-HI56KM, and CENP-LN used in (D).

(D) Pull-downs of CENP-Q and CENP-P from HeLa cell extracts with GST-PREP beads. SNARE-CENP-C1–544 (81 kDa) and CENP-HK (31.5 kDa), CENP-N (29.5 kDa) and CENP-P (33.2 kDa) are pulled down by GST-CENP-Q (30.6 kDa) and CENP-R (20.2 kDa).

(E) Control RNAi and CENP-P RNAi transfections in HeLa cells, followed by GFP, CREST, and CREST-DAPI staining. Representative images are shown. 90 min MG132.

(F) Graph showing the number of kinetochores staining with CREST in response to CENP-P RNAi and control RNAi transfections.
2008b; Minoshima et al., 2005; Okada et al., 2006). Furthermore, we suppressed the expression of individual CENP-O, -P, -Q, and -R subunits by RNAi, and we observed that reducing the level of any one of the four CENPs prevented localization of the other subunits (Figures S2F–S2H), indicating reciprocal support in kinetochore localization, as reported previously (Bancroft et al., 2015; Hori et al., 2008b; Kang et al., 2008).

We tried to reconstitute in vitro with purified proteins (Figure 2C and S3A–S3C) the recruitment hierarchy responsible for the dependencies observed in HeLa cells. CENP-C1-544 immobilized on solid phase was used as bait—in isolation or in presence of CENP-LN, CENP-HI56KM, or both—to pull down CENP-OP, CENP-QU, or CENP-R (Figure 2D). Both CENP-LN and CENP-HI56KM bound independently to CENP-C. When incubated together, an apparent increase in binding affinity, particularly evident for CENP-N, was observed. Neither CENP-OP nor CENP-QU or CENP-R bound to CENP-C1-544 beads in the presence of isolated CENP-LN or CENP-HI56KM. CENP-OP, however, readily bound when CENP-LN and CENP-HI56KM were added concomitantly to form the CENP-C1-544HI56KM complex. Isolated CENP-QU or CENP-R, on the other hand, was unable to interact with the CENP-C1-544HI56KM complex, and only did so in presence of CENP-OP or CENP-OPQU, respectively (Figure 2D). Thus, our data suggest that CENP-OP acts as a bridge between the CENP-C1-544HI56KM complex and the other subunits of the CENP-OPQU complex.

The previously determined crystal structure of the tandem RWD domains of KN1L in a linear peptide with Nsl1 from the MIS12 complex (MIS12C) (Petrovic et al., 2014) offers a possible model for the interaction of the CENP-OP RWD domains with CENP-C1-544HI56KMLN. Tyr2125Kn1 lies at the interface with Nsl1, and its mutation impairs Nsl1 binding without destabilizing the Kn1 structure (Petrovic et al., 2014). Ctf19CENP-P and CENP-P also contain aromatic residues at the equivalent position (Phe138Ctf19 and Phe116CENP-P)(Figures S3D–S3F). Glycine point mutation of this residue (CENP-P F116G) did not apparently affect the stability of the CENP-OP dimer but largely abrogated its binding to the CENP-C1-544HI56KMLN complex in vitro (Figure S3G). Furthermore, the mutant displayed reduced binding to CCAN components in immunoprecipitation (IP) assays from cell lysates (Figure S3H).

Kinetochore localization of CENP-PF116G in HeLa cells was also impaired, regardless of whether the endogenous CENP-P protein had been depleted through RNAi (Figure 2E). Thus, the mechanism of kinetochore recruitment of CENP-OP may be structurally related to the mechanism of kinetochore recruitment of the RWD domains of KN1L via an interaction with MIS12C.

The experiments in Figure 2E additionally demonstrated that depletion of CENP-P by RNAi, which destabilizes the entire CENP-OPQU complex, interferes with chromosome congression, with several chromosomes occupying positions near the spindle poles and failing to complete alignment at the metaphase plate (white arrowheads in Figure 2E, quantification in Figure 2F). These effects of the CENP-P depletion were rescued by expression of wild type CENP-P, but not of CENP-PF116G mutant, confirming the specificity of the phenotype.

Organization of the CENP-HI56KMNPQUR Complex

Two important conclusions so far are 1) that the CENP-C1-544HI56KMLN complex recruits the CENP-OPQU complex and 2) that this requires a direct interaction of CENP-OP with a composite interface created by CENP-HI56KM and CENP-LN, as summarized in Figure 3A. Because solid-phase binding assays can suffer from absorption artifacts, we asked if we could reconstitute these interactions also in solution. When combined stoichiometrically, CENP-OPQUR, CENP-HI56KM, and CENP-LN formed a single 11-subunit complex (CENP-HI56KMNPQUR) with reduced retention volume in SEC (i.e., larger and/or more elongated) in comparison to the individual subcomplexes (Figure 3B).

Omission of CENP-LN or CENP-HI56KM prevented complex assembly (Figures S4A and S4B). By AUC, the CENP-HI56KMNPQUR complex had an observed molecular mass of ~404 kDa, in excellent agreement with the predicted molecular mass of ~408 kDa calculated on the assumption that each subunit is in single copy (Figures 3C and SSA; Table S1). This result matches results obtained with the solid-phase experiments in Figure 2D and demonstrates that CENP-OPQU behaves as a coincidence detector for CENP-HI56KM and CENP-LN complexes. Furthermore, these observations indicate that CENP-C1-544 is dispensable for the interaction, although we cannot exclude that it contributes to the stabilization of CENP-HI56KMNPQUR. Importantly, CENP-C is required for kinetochore recruitment of CENP-HIKM and CENP-LN (Carroll et al., 2010; Gascoigne et al., 2011; Klare et al., 2015; Milks et al., 2009) and therefore it remains ultimately required for kinetochore targeting of CENP-OPQU.

2D class averages of negatively stained CENP-HI56KMNPQUR complex previously subjected to a mild cross-linking treatment with the GraFix procedure (Kastner et al., 2008; Figures S5B–S5D and S6G) are shown in Figure 3D. A 3D reconstruction of the complex at an approximate resolution of 23 Å showed that it has overall dimensions (in Å) of 180, 160, and 100 (Figures 3E and S5E), and is therefore largely globular. We previously described a negative-stain EM

(D) Pull-down assays using SNAP-CENP-C1-544 bait. CENP-OP binds the solid phase only in the presence of CENP-HI56KM and CENP-LN. Subsequently, CENP-QU and CENP-R can also be recruited. Shown are Western blots of the indicated species. The experiment shown is representative of three technical replicas.

(E) RNA-resistant GFP-CENP-P localized to the kinetochore after depletion of endogenous CENP-P, while GFP-CENP-PF116G did not. CREST signal (red) was unaffected by CENP-P depletion or by impaired localization of GFP-CENP-PF116G. DAPI (DNA) is shown in blue. Arrowheads indicate misaligned chromosomes. MG132 (10 μM) was added to prevent mitotic exit. Scale bar, 5 μm.

(F) Quantification of the experiment in (E). The number of cells analyzed is in parentheses. Error bars represent standard deviations. See also Figure S2 and Figure S3.
reconstruction of the CENP-H\textsuperscript{I56K} complex (Basilico et al., 2014) (Figure 3F). We therefore fitted densities for the CENP-OPQUR and CENP-H\textsuperscript{I56K} complex into the density of the CENP-H\textsuperscript{I56KLMNOPQUR} (Figure 3G, Figure S5E, and Video S1). The resulting model predicts that CENP-H\textsuperscript{I56K} and CENP-OPQUR oppose each other, with a direct contact involving the head domain of CENP-OPQUR (containing CENP-OP). We attribute to CENP-LN the substantial residual unoccupied density sandwiched between CENP-H\textsuperscript{I56K} and CENP-OPQUR (Figures 3H and S5F; Video S1). By predicting multiple contacts between CENP-LN and CENP-H\textsuperscript{I56K} with CENP-OPQUR, this model is consistent with the binding data shown in Figures 2 and 3.

Reconstitution of a 26-Subunit Kinetochore Particle Containing CENP-OPQUR

CCAN acts as a bridge between the CENP-A nucleosome in centromeric chromatin and the KMN assembly in the microtubule-binding portion of the kinetochore. We have recently reconstituted this bridge with 21 recombinant subunits covering the CENP-A nucleosome, the CENP-C\textsuperscript{1-544I56KMLN} complex, and the KMN assembly (Weir et al., 2016) (referred to as rKT21, for recombinant kinetochore with 21 subunits). Our new evidence that CENP-OPQUR binds directly to the CENP-C\textsuperscript{1-544I56KMLN} complex prompted us to ask if this interaction permitted inclusion of CENP-OPQUR in rKT21. CENP-OPQUR did not interact directly with the CENP-A nucleosome core particle (CENP-A\textsuperscript{NCP}) but co-eluted with it when combined with CENP-C\textsuperscript{1-544I56KMLN}, indicating that the latter mediates the interaction of CENP-OPQUR with CENP-A\textsuperscript{NCP} (Figures 4A and 4B).

Further inclusion of the KMN network resulted in the assembly of a particle with a retention volume smaller than any of those of the individual components (Figure 4C; individual complexes used for these experiments are shown in Figures S5G–S5J). The peak fractions of this species contained all 26 expected
subunits (4 histones of the CENP-A NCP, 12 CCAN subunits, and 10 KMN subunits, named rKT26) (Figure 4C). The CENP-OPQUR complex appeared substoichiometric in this peak, and part of it eluted in a shoulder peak corresponding to the expected elution volume for CENP-OPQUR. This observation suggests either that CENP-OPQUR binds into this larger complex with reduced binding affinity, thus undergoing partial dissociation, or that its effective stoichiometry is lower. We have previously determined that two copies of CENP-CHID56KMLN bind a single CENP-A nucleosome core particle (CENP-A NCP) (Weir et al., 2016), and it is possible that a single copy of CENP-OPQUR, rather than two, binds the CENP-C1–544HI56KMLN: CENP-A NCP complex. However, given that CENP-C1–544HI56KMLN and CENP-OPQUR form a stoichiometric complex (Figure 3B), the hypothesis that CENP-OPQUR undergoes partial dissociation from the larger complex seems more plausible. We speculate that this effect reflects a requirement for post-translational modifications that increase the binding affinity of CENP-OPQUR for rKT21 and that are still missing in our reconstitution.

Human CENP-OPQUR did not bind to the NDC80C or to the entire KMN (Figures S4C and S4D), nor did it bind to complexes

Figure 4. Reconstitution of a 26-Subunit Kinetochore (rKT26)

(A) Elution profile from analytical SEC, and subsequent SDS-PAGE analysis, of a mixture of CENP-OPQUR (5 μM) complex and CENP-A NCP (2.5 μM).

(B) Elution profile from analytical SEC, and subsequent SDS-PAGE analysis, of a stoichiometric mixture of CENP-C1–544, CENP-HI56KMLN-OPQUR (each at 5 μM), and CENP-A NCP (2.5 μM).

(C) Elution profile from analytical SEC, and subsequent SDS-PAGE analysis, of a mixture of CENP-C1–544 (red trace), the CCAN core (CENP-HI56KMLN-OPQUR, violet trace), the KMN network (orange trace) (each at 5 μM), and the CENP-A nucleosomes (grey trace) (2.5 μM) resulting in the formation of a 26-subunit complex (black trace) that links the centromeric DNA to microtubules. Enlargement of the dotted lane of the SDS-PAGE gel demonstrates that the front of the peak contains all the indicated subunits.

(D) Structural and topological organization of the 26-subunit kinetochore (rKT26) based on current and previous work (Weir et al., 2016). The drawing is approximately in scale. A crystal structure of the CENP-A nucleosome has been reported previously (Tachiwana et al., 2011). Previously, we determined crystal structures of NDC80C Bonsai (an engineered version of the NDC80 complex that retains microtubule-binding and kinetochore localization activities; Ciferri et al., 2008), of the kinetochore-targeting C-terminal domain of KNL1 (KNL1C) (Petrovic et al., 2014), and of the MIS12C (Petrovic et al., 2016), and we used negative-stain EM to obtain a first view in three dimensions of their complex (Petrovic et al., 2014). Shown in orange are experimental molecular models fitted into the EM density. The long axis of the NDC80C Bonsai, MIS12C, KNL1 complex is approximately 35 nm, but the length of the actual complex is approximately 90 nm (Huis In’t Veld et al., 2016) due to the extensive coiled-coils of NDC80C that have been trimmed from NDC80C Bonsai. This paper adds a view of CCAN to this scheme. CENP-C connects the CENP-A nucleosome, which it binds via a specific binding domain (CENP-BD), to the outer kinetochore, which it binds via a MIS12 binding domain. See also Figure S3.
of MIS12C or MIS12C:NDC80C with CENP-C1–544 (Figures S4E and S4F), a crucial link between the inner and outer kinetochore (Dimitrova et al., 2016; Gascoigne et al., 2011; Petrovic et al., 2016; Przewloka et al., 2011; Screpanti et al., 2011; Weir et al., 2016). Thus, CENP-OPQUR does not contribute to the stabilization of the connection between the inner and the outer kinetochore, a function that has instead been described for its ortholog in S. cerevisiae (the COMA complex, comprising the Ctf19CENP-P, Okp1CENP-Q, Mcm21CENP-O, and Ame1CENP-U subunits and lacking a clear CENP-R ortholog) (De Wulf et al., 2003; Dimitrova et al., 2016; Homung et al., 2014; Hyland et al., 1999; Ortiz et al., 1999; Pekgoz Altunkaya et al., 2016; Schmitzberger and Harrison, 2012; Westermann et al., 2003).

The CENP-OPQUR Complex Binds Microtubules

Previous studies with isolated recombinant CENP-Q or CENP-U identified microtubule-binding activities in both subunits (Amaro et al., 2010; Hua et al., 2011). Because CENP-Q and CENP-U form a stable complex where CENP-Q is present in single copy, instead of the oligomers observed in isolation (Amaro et al., 2010), we wanted to revisit these results with reconstituted CENP-OPQUR subcomplexes. Only the CENP-QU and CENP-OPQUR complexes, but not CENP-OP, pelleted with Taxol-stabilized microtubules in co-sedimentation assays (Figures 5A, 5B, S6C, and S6D). CENP-OP, however, pelleted with microtubules when combined with CENP-QU (Figures S6C and S6D), suggesting that CENP-QU contains a microtubule-binding activity. In isolation, CENP-R also interacted with microtubules, but its incorporation in the CENP-OPQUR complex did not increase the apparent binding affinity of the CENP-OPQUR complex for microtubules, casting doubts on the significance of the interaction seen with isolated CENP-R oligomers (Figures 5B, S6C, and S6D; and unpublished data).

Total internal reflection fluorescence (TIRF) microscopy was used to visualize single Alexa488-labeled CENP-OPQU particles at 1 nM concentration, allowing us to show that there is diffusive binding of the complex to the microtubule lattice (Figures 5C–5E). Of the diffusing particles, 26% remained bound to the lattice for the duration of the video (200 s), while 74% were observed to unbind or bind the microtubules during this time (mean time associated = 131 s). In contrast, the NDC80C, at 1 nM concentration, showed rapid binding and unbinding events (mean time associated = 1.3 s; SEM = 0.17 s; Figure 5E). Together, these data suggest that the CENP-OPQU complex is capable of mediating long-duration attachment to microtubules. In view of our recent observation that multimerization leads to a dramatic increase of the microtubule residency time of the NDC80C (Volkov et al., 2018), we cannot exclude that CENP-OPQU may form small oligomeric particles on microtubules under the condition of our assay, even if the AUC analysis with the isolated complex indicated absence of oligomerization. Further work will have to address this possibility.

At micromolar concentrations, CENP-OPQU had a very strong bundling effect on microtubules (Figure S6E). By negative-stain EM, microtubules incubated with CENP-OPQU appeared “rough” in comparison to naked microtubules (Figures 5F and S5). In several cases, it was possible to visualize individual CENP-OPQU complexes docked on microtubules (Figure 5H and S6F). The interaction with the microtubule lattice appeared to involve the base of the CENP-OPQU complex, with the head pointing away. Because CENP-QU is responsible for
microtubule binding, as shown above, we speculate that CENP-OP and CENP-QU reside in the head and base domains, respectively. Structural characterization of the complex of the S. cerevisiae homologs of CENP-O and CENP-P, the Ctf19\textsuperscript{CENP-P-Mcm21\textsuperscript{CENP-O}} complex, demonstrated that these subunits are structural paralogs, each containing tandem RWD (RING finger, WD repeat, DEAD-like helicases) domains (Schmitzberger and Harrison, 2012; Schmitzberger et al., 2017). In agreement with our model, the crystal structure of the Ctf19\textsuperscript{CENP-P-Mcm21\textsuperscript{CENP-O}} complex from S. cerevisiae fitted snugly into the density of the head domain (Figure 1I). This tentative structural model will require corroboration through high-resolution structural analyses in the future.

The CENP-O Disordered and Basic N-Terminal Tail Promotes Microtubule Binding

In agreement with the sedimentation experiments, fluorescently labeled CENP-OP (with Alexa488 through maleimide thiol chemistry) did not bind microtubules in a flow cell (Figure 6A). Alexa647-labeled CENP-QU, on the other hand, decorated microtubules, and when combined with CENP-OP allowed it to decorate microtubules, indicating that the CENP-QU subcomplex binds microtubules and carries CENP-OP along (Figure 6A).

At least at high concentrations, NDC80C binds cooperatively to the microtubule lattice, interacting along protofilaments at the alternating $ab$ and $ba$ tubulin interfaces with 4-nm spacing (Alushin et al., 2010; Ciferri et al., 2008). At a concentration of 100 nM, fluorescent recombinant NDC80C GFP strongly decorated the microtubule lattice in a flow cell (Figure 6B). Addition of CENP-OP\textsubsuperscript{QU} labeled with Alexa647 at 400 nM caused an almost complete displacement of NDC80C (at 100 nM) from microtubules, with concomitant microtubule binding of fluorescent CENP-OP\textsubsuperscript{QU}. Conversely, CENP-OP\textsubsuperscript{QU}, at 100 nM, decorated microtubules, but was displaced upon addition of 400 nM NDC80C (Figure 6B). Thus, the footprints of NDC80C and of CENP-OP\textsubsuperscript{QU} overlap on the microtubule lattice at least in part,
implying that the mode of microtubule binding of these complexes is intrinsically competitive. Furthermore, based on the relative effects of competition in these single-point assays, the binding affinities of the two complexes for microtubules appear to be in a similar range. It has been proposed that CENP-Q and NDC80C interact directly and that this promotes cooperative microtubule binding (Hua et al., 2011), but we could not recapitulate this interaction _in vitro_, as already described (Figure S4C).

Selective Sortase modification of the CENP-Q N-terminus with a fluorescein amidite (FAM) peptide prevented CENP-QU binding to microtubules (Figure 6C). Conversely, fluorescently labeled rKT21 bound microtubules, as shown previously (Weir et al., 2016) (Figure 6C). However, rKT21 did not rescue microtubule binding of FAM-labeled CENP-QU (Figure 6C), in line with the inability of CENP-QU to interact with the C1–544HI complex in rKT21. Further addition of CENP-OP, on the other hand, promoted efficient translocation of FAM-labeled CENP-QU to microtubules, confirming the prediction, based on the experiments in Figure 2D, that CENP-OP promotes the interaction of CENP-QU with rKT21 required to generate rKT26.

We were interested in understanding why modification of the CENP-Q N-terminus interferes with microtubule binding. The sequence of the N-terminal region of CENP-Q is highly basic and predicted to be disordered due to its low complexity (Figure 6D). This is highly reminiscent of NDC80 (also known as HEC1), the microtubule-binding subunit of the NDC80C, where a similarly basic and disordered N-terminal region has been implicated in microtubule binding (Cheeseman et al., 2006; Ciferri et al., 2008; DeLuca et al., 2006) (Figure 6D). To test if the N-terminal region of CENP-Q contributes to microtubule binding, we generated a deletion mutant lacking 67 N-terminal residues (CENP-Q68-C) and co-expressed it with other subunits to generate CENP-Q68-CU and CENP-OPQ68-CUR complexes (Figure 1C). An Alexa488-labeled version of the latter labeled rKT21 bound microtubules, as shown previously (Weir et al., 2018) (Figure 1D). In agreement with the prediction, and contrarily with the observation with the wild-type CENP-OPQUR complex, no microtubule binding of rKT21 or of CENP-OPQ68-CUR was observed when these complexes were combined at 25 nM concentration (Figure 6E, bottom two rows). Thus, augmented microtubule binding of rKT26 requires the microtubule binding N-terminal region of CENP-Q.

The NDC80 N-Terminal Region Functionally Replaces CENP-Qs

To further test the functional similarity of the CENP-Q and NDC80 N-terminal tails, we built a construct to express wild-type CENP-Q fused to a C-terminal eGFP (CENP-Q-eGFP) or an equivalent construct in which the N-terminal tail was replaced with that of NDC80 (CENP-QNDC80(1-80)-eGFP; Figure 7A). In cells depleted of endogenous CENP-Q, both constructs localized to kinetochores and to similar levels (Figures 7B and 7C). Importantly, depletion of CENP-Q led to a strong accumulation of chromosomes near spindle poles, indicative of congression errors (Figure 7D and Figures S7B and S7C). Expression of CENP-Q-eGFP or of CENP-QNDC80(1-80)-eGFP led to a near complete rescue of the congression phenotype, indicating that both constructs are functional. As a further control of the functionality of the CENP-Q construct, we observed that the strong reduction in CENP-E levels caused by CENP-Q depletion (originally reported by Bancroft et al., 2015) was also rescued in presence of both CENP-Q constructs (Figure 7E). Collectively, these and additional data in Figures 2E and 2F indicate that the CENP-OPQUR complex is required for chromosome alignment in HeLa cells and that the interaction with microtubules mediated by the N-terminal region of CENP-Q is important for this process. The disordered and basic N-terminal tail of NDC80, when grafted onto a CENP-Q mutant lacking its own N-terminal tail, can rescue a requirement for CENP-Q in chromosome alignment.

**Cooperative Microtubule Binding by rKT26**

The competitive binding mode of CENP-QU and NDC80C shown in Figure 6B does not imply that their binding to microtubules within kinetochores is incompatible, as the number of binding sites on the microtubule lattice vastly exceeds the estimated number of NDC80C and CENP-QU binders within a microtubule-binding unit. Rather, it may be surmised that, if incorporated into the same particle, NDC80C and CENP-OPQUR may determine an increase in microtubule-binding affinity if they were concomitantly able to bind microtubules. To test this idea, we first confirmed that CENP-OPQUR or rKT21 (which contains NDC80C) bound to microtubules in isolation in a flow cell. Individually, both decorated microtubules tightly at 400 nM, but when their concentration was reduced to 25 nM, binding of CENP-OPQUR or rKT21 to microtubules appeared drastically reduced. When added together at 25 nM, however, both CENP-OPQUR and rKT21 bound strongly to microtubules (Figure 6E).

Thus, co-existence of CENP-OPQUR and NDC80C within the same complex strongly augments the microtubule-binding activity of rKT26. We reasoned that the augmented microtubule-binding activity of rKT26 ought to be abrogated in presence of CENP-OPQ68-CUR, which does not bind microtubules. In size-exclusion chromatography experiments, CENP-OPQ68-CUR readily bound the other CCAN subunits, indicating that the deletion of the N-terminal region of CENP-Q does not affect this interaction (Figure S7A); this is also in line with the ability of the electroporated mutant complex to reach kinetochores (Figure 1D). In agreement with the prediction, and contrarily with the observation with the wild-type CENP-OPQUR complex, no microtubule binding of rKT21 or of CENP-OPQ68-CUR was observed when these complexes were combined at 25 nM concentration (Figure 6E, bottom two rows). Thus, augmented microtubule binding of rKT26 requires the microtubule binding N-terminal region of CENP-Q.

**DISCUSSION**

The comprehensive biochemical and structural analysis of the vertebrate CENP-OPQUR complex described here significantly extends previous studies (Hori et al., 2008b; Kang et al., 2011). After reconstituting rKT2 (Weir et al., 2016), we now report the reconstitution of rKT26, a 26-subunit “successor” that also incorporates the CENP-OPQUR complex. The 22 kinetochore subunits in this complex (the other four being histones) are all assembled on a single CENP-A NCNP, with at least two subunits, CENP-C and CENP-N, being able to bind CENP-A directly and
specifically (Cao et al., 2018; Carroll et al., 2009, 2010; Chittori et al., 2018; Guo et al., 2017; Kato et al., 2013; Pentakota et al., 2017; Tian et al., 2018; Weir et al., 2016).

On the basis of the distributions of its binding sites for other kinetochore proteins, we have recently proposed that CENP-C, which is predicted to be largely unstructured, may act as a "blue-print" for the assembly of kinetochores (Klare et al., 2015).

CENP-C binds MIS12C at its N terminus (Liu et al., 2016; Przewloka et al., 2011; Richter et al., 2016; Screpanti et al., 2011) and CENP-A via a motif in its central region (Kato et al., 2013). CENP-C also binds CCAN within a domain between the 3D EM reconstruction of the CENP-H\textsuperscript{D56KMLNOPQUR} complex provides the first near-comprehensive structural analysis of the CCAN, albeit at low resolution, and extends our previous analysis of CENP-H\textsuperscript{D56KM} (Basilico et al., 2014). In spite of its low resolution, the reconstruction allows important conclusions on the organization of CCAN. Most notably, the CCAN subcomplex we have studied is very compact and globular, in

MIS12C and CENP-A binding sites (Hinshaw and Harrison, 2013; Klare et al., 2015; McKinley et al., 2015; Nagpal et al., 2015; Pentakota et al., 2017) (Figure 4D). CENP-C probably meanders on and through the structure of CCAN, creating multiple contacts that stabilize it, thus explaining why its presence is so crucial for kinetochore integrity (e.g., see Carroll et al., 2010; Milks et al., 2009), even if our studies clearly argue that CCAN is endowed with substantial structural stability even in the absence of CENP-C.

The 3D EM reconstruction of the CENP-H\textsuperscript{D56KMLNOPQUR} complex provides the first near-comprehensive structural analysis of the CCAN, albeit at low resolution, and extends our previous analysis of CENP-H\textsuperscript{D56KM} (Basilico et al., 2014). In spite of its low resolution, the reconstruction allows important conclusions on the organization of CCAN. Most notably, the CCAN subcomplex we have studied is very compact and globular, in

Molecular Cell 71, 923–939, September 20, 2018 933
contrast to the fibrous organization of the KMN in the outer kinetochore (Ciferri et al., 2008; Dimitrova et al., 2016; Petrovic et al., 2014, 2016; Valverde et al., 2016). Within CCAN, CENP-N binds directly to CENP-A nucleosomes in vitro, and structural information on this interaction has recently emerged (Chittori et al., 2018; Pentakota et al., 2017; Tian et al., 2018). Besides binding directly to the CENP-A nucleosome, CCAN may serve as a spacer to position KMN for a favorable interaction with the microtubule end. A nanometer-scale map of kinetochores concluded that the CCAN subunits are clustered within approximately 20 nm along the longitudinal (kinetochore-microtubule) axis of the kinetochore (Suzuki et al., 2014). Figure 4D presents a structural model of the kinetochore that incorporates available structural and functional information, including studies shown in Figures 1, 2, 3, and 4. The architecture shown in Figure 4D probably defines a conserved module of eukaryotic kinetochores present in single copy in the “point” kinetochores of S. cerevisiae (Pluta et al., 1995), which bind a single microtubule, or in multiple copies in the “regional” kinetochore of humans, which bind ~25 microtubules (Musacchio and Desai, 2017).

Still missing from this reconstitution to completely represent the core subunits is CENP-TW (possibly operating in complex with CENP-SX; Nishino et al., 2012). Together with CENP-C, CENP-TW promotes outer kinetochore assembly by binding directly to KMN network components (Gascoigne et al., 2011; Hori et al., 2008a; Huis In’t Veld et al., 2016; Przewloka et al., 2011; Screpanti et al., 2011; Weir et al., 2016). The interaction of recombinant CENP-TW with the 26-subunit kinetochore complex we describe is weak (Basilico et al., 2014; Weir et al., 2016; and our unpublished observations; of note, this does not appear to be the case in S. cerevisiae, where Cnn1 CENP-T interacts strongly with the ortholog of the CENP-HIKM complex: Pekgöz Altunkaya et al., 2016). Recent studies suggest that vertebrate CENP-TW docks on DNA that bridges neighboring nucleosomes (Takeuchi et al., 2014; Thakur and Henikoff, 2016), and therefore its incorporation into our recombinant particles may require the engineering of suitable high-affinity chromatin templates.

CENP-TW is required for CENP-OQUR recruitment to kinetochores (Gascoigne et al., 2011), but this likely reflects the established role of CENP-TW in stabilizing CENP-HIKM at the kinetochore (Basilico et al., 2014; Carroll et al., 2010; Foltz et al., 2006; Gascoigne et al., 2011; Hori et al., 2008a; Huis In’t Veld et al., 2016; Nishino et al., 2012; Okada et al., 2006; Pekgöz Altunkaya et al., 2016; Samejima et al., 2015; Wood et al., 2016), because we failed to observe a direct interaction of CENP-OQUR with CENP-TW (M.E.P. and A.M., unpublished data).

An important conclusion is that CENP-OQUR occupies an outermost position of the inner kinetochore, as its recruitment there requires concomitant binding to the centromere-proximal subunits CENP-LN and CENP-HIKM. Conversely, CENP-OQUR is dispensable for recruitment of the proximal subunits (Eskat et al., 2012; Foltz et al., 2006; Hori et al., 2008b; Izuta et al., 2006; Kagawa et al., 2014; McClelland et al., 2007; McKinley et al., 2015; Minoshima et al., 2005; Okada et al., 2006; Samejima et al., 2015) (Figure 7F). This organization may differ significantly in S. cerevisiae, where the COMA complex appears to occupy an upstream position in the recruitment order of kinetochore subunits (Hinshaw et al., 2017; Pekgöz Altunkaya et al., 2016; Schmitzberger et al., 2017). Future studies will have to clarify what molecular adaptations underlie these differences. CENP-OP and CENP-OQ form stable subcomplexes, which explains why CENP-O and CENP-P on the one hand, and CENP-Q and CENP-U on the other, are interdependent for physical stability in chicken DT40 cells (Hori et al., 2008b). In our work, CENP-OP emerged as the main factor promoting kinetochore targeting of CENP-OQUR, even if CENP-Q and CENP-U have been shown to further stabilize it (Bancroft et al., 2015; Hori et al., 2008b; Kang et al., 2006). The interaction of Ame1 CENP-Q with the orthologs of CENP-HIKM and CENP-LN in S. cerevisiae was shown to require Ctf19 CENP-P and Mcm21 CENP-O (Pekgöz Altunkaya et al., 2016). A motif located near the C-terminus of Okp1 CENP-Q mediates a physical interaction with the RWD domains of the Ctf19 CENP-P, Mcm21 CENP-O dimer (Schmitzberger et al., 2017). The Okp1 motif, however, does not appear to be conserved outside closely related yeast species, leading us to speculate that the interaction of the human CENP-OP and CENP-OQ subcomplexes studied here uses different determinants.

Here, we have also identified a novel microtubule-binding site in the basic N-terminal tail of CENP-Q. Many features of the CENP-Q N-terminal tail, most notably its highly basic isoelectric point and its tendency to structural disorder due to low sequence complexity, are highly reminiscent of the N-terminal tail of NDC80. The precise contribution of the latter to microtubule binding remains poorly understood from a mechanistic perspective, but there is ample evidence that it is required for bio-orientation and tight microtubule binding of NDC80 (Alushin et al., 2010, 2012; Cheeseman et al., 2006; Ciferri et al., 2008; Deluca et al., 2006, 2011, 2018; Zaytsev et al., 2014, 2015). Two crucial differences between the CENP-Q and NDC80 tails are that 1) the NDC80 tail flanks a calponin homology (CH) domain that contributes to microtubule binding by NDC80 (Ciferri et al., 2008; Wei et al., 2007), and by structural modeling we found no conclusive evidence that CENP-Q (or CENP-U) contain calponin homology (CH) domains (unpublished data); and 2) the NDC80 tail is subject to regulation by phosphorylation by multiple kinases, including Aurora A and B, which may phosphorylate up to nine consensus sites in the tail, and Cdk1, for which there is at least one consensus site (Cheeseman et al., 2006; Ciferri et al., 2008; Deluca et al., 2006, 2011, 2018; Zaytsev et al., 2014, 2015). Inspection of the CENP-Q N-terminal tail reveals only one or two Aurora consensus sites and no Cdk1 site.

While future studies will have to address the functional implications of these differences, the ability of the NDC80 N-terminal tail to replace the CENP-Q tail and promote chromosome alignment is striking. Given that CENP-OQUR occupies, with the CCAN, a position near the “bottom” of the kinetochore (Figure 4D), we surmise that its microtubule-binding activity may become especially important after establishment of end-on attachment. A previous study identified NDC80C as a passive force generator within vertebrate kinetochores and recognized the existence of an active force generator whose molecular identity remained unclear but whose position within kinetochores is compatible with that attributed to the CENP-OQUR complex (Dumont et al., 2012). In TIRF microscopy experiments, we
observed rare events in which individual CENP-OPQU complexes labeled with Alexa488 tracked depolymerizing microtubules (unpublished data), a property expected for an active force generator. The tools we describe here will enable a detailed study of this hypothesis.

The similarities between NDC80C and CENP-OPQU are not limited to the basic disordered N-terminal tails. Both complexes appear to “subdivide labor” by assigning kinetochore targeting and microtubule binding to different subcomplexes. In NDC80C, SPC24:SPC25 and NDC80:NUF2 subcomplexes mediate kinetochore recruitment and microtubule binding, respectively. In CENP-OPQU the same functions are attributed to CENP-OP and CENP-QU, respectively. CENP-O, CENP-P, SPC24, and SPC25 are structurally related proteins containing RWD domains (Ciferri et al., 2008; Petrovic et al., 2014; Schmitzberger and Harrison, 2012; Wei et al., 2006) (Figure 7G).

On the other hand, the extent to which CENP-QU is structurally related to the NDC80:NUF2 dimer is unclear. CENP-Q and CENP-U are predicted to contain several α helices (Westermann and Schleiffer, 2013), the main secondary structure element of CH domains, and have predicted C-terminal coiled-coils (Figure 1B) like NDC80 and NUF2.

Although the phenotypic consequences of depleting CENP-OPQU subunits vary in severity depending on the affected cell type (Kagawa et al., 2014; McKinley et al., 2015), our results are largely consistent with previous studies that identified severe chromosome alignment problems in cells depleted of CENP-OPQU (Bancroft et al., 2015; Hori et al., 2008b; Hua et al., 2011; McAinsh et al., 2006; McClelland et al., 2007; Minoshima et al., 2005; Toso et al., 2009). We further document the chromosome alignment problems caused by CENP-P depletion in Figures S7D–S7F. The importance of CENP-OPQU is further corroborated by a recent study that identified CENP-Q and CENP-P in a group of gene products involved in chromosome alignment and whose depletion is compatible with cell viability but only in presence of a functional spindle assembly checkpoint (Raaijmakers et al., 2018). This is consistent with the idea that, in the absence of the CENP-OPQU complex, achievement of bi-orientation is delayed and a call on the spindle checkpoint to delay mitotic exit is issued, without which cells undergo a catastrophic, lethal division. Our analysis indicates that, besides its contributions to the recruitment and regulation of Plk1 and CENP-E (Ahonen et al., 2005; Bancroft et al., 2015; Hori et al., 2008b; Kang et al., 2006, 2011; Nishino et al., 2006), CENP-OPQU contributes to chromosome alignment through direct microtubule binding. In conclusion, our study fills an important gap in our understanding of human kinetochores and paves the way to full functional reconstitution of kinetochore function in the test tube.

STAR METHODS

Detailed methods are provided in the online version of this paper and include the following:

- **Key Resources Table**
- **Contact for Reagent and Resource Sharing**
- **Experimental Model and Subject Details**
- **Method Details**
  - Plasmids
  - Protein expression and purification
  - Protein fluorescence labeling
  - Electroporation of CENP-OPQUR into mitotic and interphase cells
  - Analytical SEC analysis
  - Co-infection and co-purification of CENP-R with CENP-OPQUR subunits
  - Sample preparation for electron microscopy
  - Preparation of negative stain specimens and electron microscopy
  - Analytical ultracentrifugation (AUC)
  - Microtubule co-sedimentation assays
  - Microtubule binding assay on spinning disc confocal microscope
  - TIRF microscopy
  - SNAP-CENP-C pull-down experiments
  - Cell culture and transfection
  - Immunofluorescence
  - Live cell imaging
  - Immunoprecipitation and immunoblotting
  - Tail-swap experiment

SUPPLEMENTAL INFORMATION

Supplemental Information includes seven figures and one table and one video and can be found with this article online at https://doi.org/10.1016/j.molcel.2018.07.038.

ACKNOWLEDGMENTS

We thank all members of the Musacchio laboratory for helpful discussions and comments. A.M. gratefully acknowledges funding by the Max Planck Society, the European Research Council (ERC) Advanced Investigator Grant RECEPIANCE (proposal number n’ 669686), and the DFG’s Collaborative Research Centre (CRC) 1093. A.D.M. is supported by a Wellcome Trust Senior Investigator Award (grant number 106151/Z/14/Z) and a Royal Society Wolfson Research Merit Award (grant number WM150020). S.R. gratefully acknowledges the Max Planck Society and the European Research Council under the European Union’s Seventh Framework Programme (FP7/ 2007–2013; grant no. 615984).

AUTHOR CONTRIBUTIONS

M.E.P. carried out biochemical purifications, in vitro binding and reconstitution assays, and microtubule-sedimentation assays. M.E.P. and D.P. carried out EM data preparations and collection, and D.P. performed EM data analysis and reconstructions. C.M.S. carried out kinetochore localization and alignment assays, RNAi depletions except in Figures 2E, 2F, and 7, and IP experiments in Figure S3H. A.C.F. and M.E.P. carried out microtubule binding analyses by fluorescence microscopy with the help of Y.-C.L., except TIRF assays in Figures 5C–5E. M.E. carried out TIRF assays. P.A. carried out localization and rescue experiments with CENP-P mutant and the CENP-Q tail-swap experiments. A.P. carried out ultracentrifugation analyses. S.M. carried out electroporation experiments and contributed to quantitative data analyses. J.R.W. and S.P. contributed essential reagents. M.E.P., D.P., C.M.S., S.M., M.E., and P.A. contributed to data visualization. S.R. supervised the EM work. A.D.M. supervised TIRF experiments and the cell-biological analysis of CENP-P and CENP-Q mutants. A.M. supervised and administered the
research team, contributed to data visualization, and wrote the paper with contributions from all authors.

#### KEY RESOURCES TABLE

| REAGENT or RESOURCE | SOURCE | IDENTIFIER |
|---------------------|--------|------------|
| **Antibodies**      |        |            |
| Rabbit polyclonal GFP | ABCAM | #AB6556; RRID: AB_305564 |
| Rabbit polyclonal anti-CENP-OP | Generated in house | N/A |
| Mouse monoclonal anti-CENP-P | ABCAM | #AB66058; RRID: AB_1523338 |
| Goat polyclonal anti-CENP-QU | Generated in house | N/A |
| Mouse monoclonal anti-CENP-Q | ABCAM | #AB57539; RRID: AB_940733 |
| Mouse monoclonal anti-CENP-R | ABCAM | #AB57098; RRID: AB_304751 |
| Rabbit polyclonal anti-CENP-HK | Generated in house | #SI0930 |
| Mouse monoclonal anti-CENP-A | Gene Tex | #GT13939; RRID: AB_369391 |
| Mouse monoclonal anti-CENP-A | ABCAM | #AB13939; RRID: AB_300766 |
| Rabbit polyclonal anti-CENP-C (23-410) | Trazzi et al., 2009 | #SI410 |
| Rabbit polyclonal anti-CENP-N (1-212) | Generated in house | N/A |
| Rabbit polyclonal anti-CENP-E | Meraldi Lab; Meraldi et al., 2004 | N/A |
| Human anti-centromere (CREST) | Antibodies Inc. | Cat#15-234-0001; RRID: AB_2687472 |
| **Bacterial and Virus Strains** |        |            |
| E.coli: BL21(DE3)-RIL strain | Agilent Technologies | #230240 |
| **Chemicals, Peptides, and Recombinant Proteins** |        |            |
| HRV 3C Precision Protease | Generated in house | N/A |
| TEV Protease | Generated in house | N/A |
| Lambda phosphatase | Generated in house | N/A |
| Protease-inhibitor mix HP Plus | Serva | Cat#39107 |
| Sortase A delta 59 (S.aureus) | Hidde Ploegh Lab | Addgene: Cat#51139 |
| Alexa Fluor 488 C5 maleimide Protein labeling kit | ThermoFisher | #A10254 |
| Alexa Fluor 647 C2 maleimide Protein labeling kit | ThermoFisher | #A20347 |
| Alexa Fluor 405 Carboxylic acid, succinimidyl ester Protein labeling kit | ThermoFisher | #A30000 |
| NHS-Rhodamine labeling kit | Thermo Scientific | #46406 |
| FAM-LPETGG | Genscript | N/A |
| PhosSTOP phosphatase inhibitor | Roche | Cat#04906845001 |
| (+)-S-Trityl-L-cysteine (STLC) | Sigma Aldrich | #164739 |
| RO-3306 | Millipore | #217699 |
| MG-132 | Calbiochem | CAS 133407-82-6 |
| MG-132 | Sigma | SML1135 |
| Uranyl formate | SPI Supplies | CAS#16984-59-1 |
| Fetal bovine serum (FBS) | Clonetech | #631107 |
| Fetal bovine serum (FBS) | Sigma | Cat:f7524 Batch:111M3395 |
| Zeocin | Invitrogen | Cat#R25001 |
| L-glutamine | PAN Biotech | P04-80100 |
| Nocodazole | Sigma | Cat#M1404 |
| CENP-C (1-544) | Musacchio Lab; Screpanti et al., 2011 | N/A |
| CENP-HIKM | Musacchio Lab, Basilico et al., 2014 | N/A |
| CENP-LN | Musacchio Lab, Pentakota et al., 2017 | N/A |
| CENP-CHIKM | Musacchio Lab; Klare et al. 2015 | N/A |
| NDC80 complex | Musacchio Lab; Huis In ’t Veld et al., 2016 | N/A |

CONTACT FOR REAGENT AND RESOURCE SHARING

Further information and requests for reagents may be directed to and will be fulfilled by Andrea Musacchio (andrea.musacchio@mpi-dortmund.mpg.de).

EXPERIMENTAL MODEL AND SUBJECT DETAILS

cDNAs used for expression of recombinant proteins were either of human origin, or generated synthetically based on human sequences. HeLa (female Cervix Adenocarcinoma) and USOS cells were grown in DMEM (PAN Biotech) supplemented with 10% FBS, penicillin and streptomycin and 2 mM L-glutamine. Cells were grown in a humidified atmosphere of 37°C and 5% CO₂.

METHOD DETAILS

Plasmids

For expression and purification of recombinant proteins, synthetic codon optimized DNA (Genscript) encoding human CENP-O, CENP-P, CENP-Q, CENP-U and CENP-C were used. The gene encoding for CENP-R was PCR amplified from human cDNA. CENP-R was subcloned in pGEX-6P-2rbs, a modified pGEX-6P vector (GE Healthcare) as a C-terminal 3C precision cleavable tag fusion to the sequence encoding GST and in Multibac pUCDM vector with no tag. CENP-P and CENP-P F116G were subcloned in a MultiBac pFL-derived vector (Bieniossek et al., 2012) with an N-terminal TEV cleavable 6xHis tag, under the control of the polh promoter. A codon optimized human CENP-O was subcloned in the 2nd MCS of the same vector, under the control of the p10 promoter. Simultaneously, others pFL-based vectors were created with an N-terminal TEV cleavable 6xHis tag on CENP-Q, or CENP-Q^S8-C and CENP-U under the control of the polh and p10 promoters, respectively. CENP-C (residues 1 to 544) was PCR amplified using a forward primer carrying BglII and a reverse primer carrying BamH1-Stop-SalI and subsequently cloned in the first cassette of pGEX-6P-2rbs. The SNAP tag was amplified with primers carrying BamH1 (forward) and SalI (reverse) and was cloned into the pGEX-CENP-C^1-544 construct using the same sites resulting in C-terminal tagging. Site-directed mutagenesis, performed with QuickChange Mutagenesis kit (Agilent Technologies) was used to generate mutant versions of recombinant proteins. Constructs were sequence verified.

Plasmids for stable cell lines were generated in pCDNA5/FRT/TO-EGFP-IRES, a modified version of the pCDNA5/FRT/TO vector (Invitrogen, Carlsbad, CA). The control plasmid for EGFP expression was created by PCR amplifying the EGFP sequence from
Protease to separate CENP-C 1-544-SNAP from GST. The sample containing CENP-C 1-544 was loaded onto a Resource S 6 ml column/C14

Escherichia coli BL21 (DE3) cells harboring vectors expressing CENP-R were grown in Terrific Broth at 37°C for 0.6 - 0.8, when 0.2 mM IPTG was added and the culture was grown at 18°C for ~15 hours. Cell pellets were resuspended in lysis buffer (20 mM Tris/HCl pH 6.8, 300 mM NaCl, 10% glycerol and 5 mM 2-mercaptoethanol) supplemented with protease inhibitor cocktail (Serva), lysed by sonication and cleared by centrifugation at 108,000 g at 4°C for 1 hour. The cleared lysate was filtered (0.8 µm) and applied to Glutathione Sepharose 4 Fast Flow beads (GE Healthcare) pre-equilibrated in lysis buffer, incubated at 4°C for 2 hours, washed with 50 volumes of lysis buffer and subjected to an overnight cleavage reaction with HRV 3C Prescision Protease (in house generated) to separate CENP-R from GST. The sample containing CENP-R was loaded onto a Superdex 200 16/60 SEC column (GE Healthcare) pre-equilibrated in SEC buffer (20 mM Tris/HCl pH 6.8, 500 mM NaCl, 5% (v/v) glycerol and 1 mM TCEP). Fractions containing CENP-R were concentrated, flash-frozen in liquid nitrogen and stored at ~80°C.

Expression and purification of CENP-OPQUR (and CENP-OPQUR-U, CENP-OPQU, CENP-OP (and CENP-OPF116G), and CENP-O) complexes was carried out in insect cells using a MultiBac system. Production of high-titer V2 virus was carried out separately for pFL-CENP-P-6xHis:CENP-O, pFL-CENP-Q-6xHis:CENP-U and pUCDM-CENP-R in Sf9 cells. Tnalo38 insect cells (Hashimoto et al., 2012) were used for expression (96 hours, 27°C) after which the cells were centrifuged, washed once in PBS, and resuspended in lysis buffer. Cell pellets infected with CENP-OP (or its mutants) virus were resuspended in lysis buffer (20 mM Tris/HCl pH 8.0, 300 mM NaCl, 5% imidazole, 5% (v/v) glycerol and 5 mM 2-mercaptoethanol) supplemented with protease inhibitor cocktail, lysed and cleared. The cleared lysate was applied to 5 ml HisTALON Cartridges pre-packed with TALON Superflow Resin (Clontech) pre-equilibrated in lysis buffer, washed with 10 volumes of lysis buffer. Bound proteins were eluted with lysis buffer supplemented with 250 mM imidazole. Tag cleavage with TEV protease (in house production) was performed for 15 hours at 4°C and the fractions containing the CENP-OP complex were then diluted in 10 volumes of 20 mM Tris/HCl pH 8.0, 5% glycerol, 0.5 mM EDTA and 1 mM DTT. Resource Q anion exchange chromatography column (GE Healthcare) was pre-equilibrated in 20 mM Tris/HCl pH 8.0, 30 mM NaCl, 5% (v/v) glycerol, 0.5 mM EDTA and 1 mM DTT. The sample was eluted with a linear gradient of 300 - 1000 mM NaCl in 15 bed column volumes. Fractions containing CENP-R were pooled, concentrated and loaded onto a Superdex 200 16/60 SEC column (GE Healthcare) pre-equilibrated in SEC buffer (20 mM Tris/HCl pH 6.8, 500 mM NaCl, 5% (v/v) glycerol and 1 mM TCEP). Fractions containing CENP-R were concentrated, flash-frozen in liquid nitrogen and stored at ~80°C.

Cell pellets infected with CENP-QU, CENP-OPQUR-68-C, CENP-OPQU, CENP-OPQUUR and CENP-OPQUR-68-CUR viruses were resuspended in lysis buffer (20 mM Tris/HCl pH 6.8, 300 mM NaCl, 5% imidazole, 5% glycerol and 5 mM β-mercaptoethanol) supplemented with protease inhibitor cocktail, lysed and cleared. The cleared lysate was applied to 5ml HisTALON column pre-equilibrated in lysis buffer, washed with 10 volumes of lysis buffer. Bound proteins were eluted with lysis buffer supplemented with 250 mM imidazole. Tag cleavage was performed with TEV protease. The sample was loaded on 5 ml HiTrap Heparin HP column (GE Healthcare) pre-equilibrated in 20 mM Tris/HCl pH 6.8, 300 mM NaCl, 5% glycerol, 0.5 mM EDTA and 1 mM DTT. The sample was eluted with a linear gradient of 300 mM - 1M NaCl in 15 bed column volumes. Fractions containing CENP-R were pooled, concentrated and loaded onto a Superdex 200 10/30 or 16/60 SEC column (GE Healthcare) pre-equilibrated in SEC buffer (20 mM Tris pH 8.0, 150 mM NaCl, 5% (v/v) glycerol and 1 mM TCEP). Fractions containing CENP-OP complex were concentrated, flash-frozen in liquid nitrogen and stored at ~80°C.

Escherichia coli BL21 (DE3) cells harboring vectors expressing CENP-C1-544-SNAP were grown in Terrific Broth at 37°C to an OD600 of 0.6 - 0.8, at which time 0.2 mM IPTG was added and the culture was grown at 18°C for ~15 hours. Cell pellets were resuspended in lysis buffer (25 mM Na-Hepes pH 7.5, 300 mM NaCl, 1 mM DTT and 1 mM PMSF) supplemented with protease inhibitor cocktail (Serva), lysed by sonication and cleared by centrifugation at 108,000 g at 4°C for 1 hour. The cleared lysate was filtered (0.8 µm) and applied to Glutathione Sepharose 4 Fast Flow beads (GE Healthcare) pre-equilibrated in lysis buffer, incubated at 4°C for 2 hours, washed with 50 volumes of lysis buffer and subjected to an overnight cleavage reaction with HRV 3C Preciison Protease to separate CENP-C1-544-SNAP from GST. The sample containing CENP-C1-544-SNAP was loaded onto a Resource S 6 ml column (GE Healthcare) pre-equilibrated in 20 mM Tris/HCl pH 6.8, 300 mM NaCl, 5% glycerol, 0.5 mM EDTA and 1 mM DTT. The sample was eluted with a linear gradient of 300 - 2000 mM NaCl in 15 bed column volumes. Fractions containing CENP-C1-544-SNAP were...
pooled, concentrated and loaded onto a Superdex200 16/60 SEC column (GE Healthcare) pre-equilibrated in SEC buffer (20 mM Tris/HCl pH 6.8, 500 mM NaCl, 5% (v/v) glycerol and 1 mM TCEP). Fractions containing CENP-C were concentrated, flash-frozen in liquid nitrogen and stored at -80°C. Other proteins were purified with detailed protocols (Basilico et al., 2014; Klare et al., 2015; Petrovic et al., 2014; Petrovic et al., 2010; Tachiwana et al., 2015; Weir et al., 2016).

**Protein fluorescence labeling**

CENP-OP, CENP-QU, CENP-Q<sub>68-C14</sub>, CENP-OPQU, CENP-OPQUR, CENP-OPQ<sub>68-C14</sub>, CENP-LN, and the KMN complex were labeled using different Alexa Fluor protein labeling kit (Thermo Fisher Scientific) according to the manufacturer instructions. Purified S. aureus Sortase (Guimaraes et al., 2013) was used to label CENP-QU with LPETGG peptides with a N-terminally conjugated fluorescein amidite (FAM) (Genscript). Labeling was performed for ~14 hr at 4°C in the presence of 10 mM CaCl<sub>2</sub> using molar ratios of Sortase, CENP-QU, and peptide of approximately 1:20:200. CENP-QU<sub>FAM</sub> was separated from Sortase and the unreacted peptides by size-exclusion chromatography.

**Electroporation of CENP-OPQUR into mitotic and interphase cells**

HeLa cells depleted for both CENP-P and CENP-Q were harvested, washed in PBS and electroporated with 3.5 µM of either recombinant Alexa-488 labeled CENP-OPQUR or CENP-OPQ<sub>68-C14</sub>. As control we used Alexa-488. Following electroporation (Neon Transfection System, Thermo Fisher) and recovery, cells were either fixed for IF, or synchronized in G2 with 9 µM RO-3306 (Millipore) for 16 hours and then released from G2 in the presence of 5 µM STLC for 2 hours (Sigma-Aldrich). Following STLC wash-out, cells were grown for 150 minutes in media containing 5 µM MG132 (Calbiochem), fixed, prepared for immunofluorescence analysis and then scored for the presence of un-congressed chromosomes. Results are representing the average and standard deviation of two replicated experiments. In total, between 603 and 731 cells were scored for each condition. Experiments were imaged on a Deltavision Elite System (see below for description). Scale bar is 5 µm.

**Analytical SEC analysis**

Analytical size exclusion chromatography was carried out on a Superdex 200 5/150 or Superose 6 5/150 in a buffer containing 20 mM Na-HEPES pH 7.5, 300 mM NaCl, 5% glycerol and 1 mM TCEP on an ÄKTA micro system. All samples were eluted under isocratic conditions at 4°C in SEC buffer (20 mM HEPES pH 7.5, 300 mM NaCl, 5% Glycerol and 1 mM TCEP) at a flow rate of 0.2 ml/min. Elution of proteins was monitored at 280 nm. 100 µl fractions were collected and analysed by SDS-PAGE and Coomassie blue staining. To detect the formation of a complex, proteins were mixed at the concentrations of 5 µM (except CENP-ANCP, with a concentration of 2.5 µM) in 50 µl, incubated for at least 1 hr on ice and then subjected to SEC.

**Co-infection and co-purification of CENP-R with CENP-OPQUR subunits**

For each His-pull-down experiment, 50 ml of freshly diluted Tnao38 cells at a density of 106 cells/ml in serum-free medium (Sf-900 II SFM, Life Technologies) were co-infected with CENP-R virus and CENP-O/His-CENP-P or/and CENP-U/HisCENP-Q viruses using a virus: culture ratio of 1:30 for each virus at 27°C for 96 hours. Cell pellets were resuspended in lysis buffer (20 mM Tris pH 6.8, 500 mM NaCl, 5 mM imidazole, 10% (v/v) glycerol and 1 mM TCEP) supplemented with protease inhibitor cocktail (Serva), lysed by sonication and cleared by centrifugation at 108,000 g at 4°C for 30 min. The cleared lysate was applied to 1 ml HisTALON column (GE Healthcare) pre-equilibrated in lysis buffer, washed with 10 volumes of lysis buffer and eluted with lysis buffer supplemented with 250 mM imidazole. Samples of total lysate, supernatant, flow through and elution were analysed by SDS-PAGE, Coomassie blue staining and by western blotting.

**Sample preparation for electron microscopy**

The protein samples (CENP-OPQU and CENP-OPQUR) were separated on a Superdex 200 10/300 or Superose 6 10/300 SEC column (pre-equilibrated in 20 mM Na-HEPES pH 7.5, 300 mM NaCl and 1 mM TCEP). The fractions containing the 11 proteins complex were pooled and concentrated to 15 µM. Purified CENP-H<sub>110Km</sub>, CENP-LN and CENP-OPQUR complexes were incubated at 15 µM in 500 µl for 1 hour at 4°C and separated on a Superose 6 10/300. The fractions containing the 11 proteins complex were pooled and concentrated to 15 µM. Samples were purified and stabilized via the GraFix method (Kastner et al., 2008): two 2 ml gradients ranging from 20 to 50% glycerol in 20 mM Na-HEPES pH 7.5, 300 mM NaCl and 1 mM TCEP were set up. In one of the gradients, the 50% solution contained 0.025% glutaraldehyde. 30 µl of sample was applied to each gradient and centrifuged by ultracentrifugation at 150,000 g at 4°C for 16 hours. The samples from the cross-linked gradient and the non-cross-linked gradient were fractionated and analyzed by SDS-PAGE, Coomassie blue staining and immunoblotting. The fractions of interest were buffer exchanged to 20 mM HEPES pH 7.5, 300 mM NaCl, 2.5% (v/v) glycerol and 1 mM TCEP with PD SpinTrap G-25 column (GE Healthcare) prior EM experiment. 4 µl of the samples was used non-diluted. To analyze microtubule bundling by CENP-OPQUR, 4 µl of the pellets fraction of the microtubule co-sedimentation assay (prepared as described below) was used non-diluted.

**Preparation of negative stain specimens and electron microscopy**

Negative stain specimens were prepared as described previously (Bröcker et al., 2012). 4 µl of the cross-linked sample were absorbed at 25°C for 1 min onto freshly glow-discharged 400 mesh carbon-coated copper grids (G2400C, Plano GmbH, Wetzlar,
Germany). Depending on particle density incubation time was elongated to 30 min in a humidity-controlled environment. Excess sample was blotted by touching a Whatman filter paper and washed with four droplets of SEC buffer and exposed to freshly prepared 0.75% uranyl formate solution (SPI Supplies/Structure Probe, West Chester, PA) for about 1 min. Excess negative stain solution was blotted and the specimen air-dried. Specimens were inspected with a JEM1400 microscope (Jeol, Tokyo, Japan) equipped with a LaB6 cathode and operated at an acceleration voltage of 120 kV. Digital micrographs were recorded at a corrected magnification of 82,524x using a 4k x 4k CMOS camera F416 (TVIPS, Gauting, Germany). Single particles were manually selected, aligned and classified using the Iterative Stable Alignment and Clustering (ISAC) approach implemented in SPHIRE (www.sphere.mpg.de) (Moriya et al., 2017). The initial datasets contained 4745, 3260, 10515 single particles for the CENP-OPQU, -OPQUR, -HI\textsuperscript{35S}KMLNOPQUR complexes respectively. The best ISAC class averages were used to calculate the 3D reconstruction using the VIPER approach (Penczek et al., 2014). The complete dataset of raw particles was used to refine the initial models. For CENP-OPQU and -OPQUR the iterative projection matching (sxali3d) implemented in SPHIRE was used until convergence was achieved. The CENP-HI\textsuperscript{35S}KMLNOPQUR complex was refined using the Meridien implemented in SPHIRE (Moriya et al., 2017). The resolution of the final reconstructions was estimated by the Fourier shell correlation (FSC) criterion 0.5 to be 22-23 Å. UCSF Chimera (Pettersen et al., 2004) was used to visualize and analyze the EM data and to prepare EM figures. Fitting of the subcomplexes was done using the implemented “fit in map” function of Chimera. The 3D reconstruction of the CENP-HI\textsuperscript{35S}KM complex (green) was published before (Basilico et al., 2014).

**Analytical ultracentrifugation (AUC)**

Sedimentation velocity experiments were performed in an Optima XL-A analytical ultracentrifuge (Beckman Coulter, Palo Alto, US-CA) with Epon charcoal-filled double-sector quartz cells and an An-60 Ti rotor (Beckman Coulter, Palo Alto, US-CA). Samples were centrifuged at 203,000g at 20 °C and 500 radial absorbance scans at either 280 nm and collected with a time interval of 1 min. Data was analysed using the SEDFIT software (Schuck, 2000) in terms of continuous distribution function of sedimentation coefficients (c(S)). The protein partial specific volume was estimated from the amino acid sequence using the program SEDNTERP. Analysis of CENP-OP was carried out at 20 °C in 20 mM Tris pH 6.8, 5% glycerol, 300 mM NaCl and 1 mM TCEP (leading to values of buffer density of 1.02542 g/ml and viscosity of 1.199 cP). Analysis of CENP-OP is was carried out at 20 °C in 20 mM Tris pH 8.0, 5% glycerol, 300 mM NaCl and 1 mM TCEP (leading to values of buffer density of 1.02542 g/ml and viscosity of 1.199 cP). Analysis for CENP-OPQU and CENP-HI\textsuperscript{35S}KMLNOPQUR were performed in 20 mM Na-HEPES, 5% glycerol, 300 mM NaCl and 1 mM TCEP (leading to values of buffer density of 1.04039 g/ml and viscosity of 1.300 cP). Analysis of CENP-OPQUR was carried out at 20 °C in 20 mM Tris pH 6.8, 5% glycerol, 500 mM NaCl and 1 mM TCEP (leading to values of buffer density of 1.03952 g/ml and viscosity of 1.217 cP). The calculate values of the partial specific volume [V(\bar{r}), inverse of density] at 20 °C for CENP-R is 0.73570 ml/g, CENP-OP is 0.73725 ml/g, CENP-QU is 0.73576 ml/g, CENP-HI\textsuperscript{35S}KMLNOPQUR is 0.73565 ml/g and for CENP-HI\textsuperscript{35S}KM the 0.72975 ml/g.

**Microtubule co-sedimentation assays**

Tubulin was purchased from Cytoskeleton, Inc. (Denver, CO) and was polymerized according to manufacturer’s instructions. Microtubules and proteins were mixed in a final volume of 20 µl in 80 mM Pipes, pH 6.8, 125 mM KCl, 2 mM MgCl\textsubscript{2}, 1 mM EGTA and 10 µM Taxol. 0 and 5 µM taxol-stabilized microtubules (tubulin dimer concentration), and 1 µM protein of interest (protein monomer concentration) were mixed in 20 µl reactions. Reaction mixtures were incubated for 10 min at room temperature, transferred onto 120 µl of cushion buffer (80 mM Pipes, pH 6.8, 125 mM KCl, 1 mM MgCl\textsubscript{2}, 1 mM EGTA, 50% glycerol and 10 μM taxol) and ultracentrifuged at 350,000 g for 10 min at 25 °C. Supernatants and pellets were analyzed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE). Quantification was carried out as described previously (Ciferri et al., 2008). Briefly, gel densitometry was carried out with Image Lab (Biorad). Bound fractions were obtained by dividing values of the pellet fraction by the sum of pellet and supernatant. Normalized binding data was fitted using GraphPad Prism (GraphPad software, Inc.).

**Microtubule binding assay on spinning disc confocal microscope**

Cover slips and glass slides were cleaned by sonication in isopropanol and 1 M KOH or 1% Hellmanex and 70% ethanol, respectively. After functionalization of cover slips with 5% biotinylated poly-L-lysine- PEG for 30 min, flow cells were created with a volume of 10-15 µl. Flow cells were passivated with 1% pluronic F-127 for 1 h and coated with avidin for 30-45 min. After incubation with 100 nM microtubules (10% biotinylated, 10% Rhodamine labeled, Cytoskeleton, Inc., polymerized according to manufacturer’s instructions) for 10-20 min. Proteins of interest were added in 80 mM Pipes (pH 6.8), 125 mM KCl, 1 mM EGTA, 1 mM MgCl\textsubscript{2} and 20 µM Taxol). Flow cells were sealed with wax and imaged with spinning disc confocal microscopy on a 3i Marianas system.

**TIRF microscopy**

The experiments were performed and analysed as described previously (Drechsler and McAinsh, 2016) with the following modifications: Each flow cell contained either 1 nM Alexa488-labeled CENP-OPQU, 1 nM Alexa488-labeled CENP-OPQUR, or 1 nM Alexa488-labeled NDC80 in 80 mM Pipes, pH 6.8, 1 mM MgCl\textsubscript{2}, 1 mM EGTA, 1 mM DTT, 20 mM glucose, 0.1 mg/ml k-casein, 0.54 mg/ml glucose oxidase and 0.27 mg/ml catalase. Taxol-stabilised microtubules were labeled 1:30 with biotin and Hilyte647.
(Cytoskeleton) and bound to the glass surface of a flow chamber. The assay mix was then flowed into the chamber and sealed with VALAP. Time-lapse sequences for Alexa488-labeled CENP-OPQU (488 nm excitation, exposure 100 ms, 1 fr/s) were recorded for a duration of 200 s at 35°C; longer videos were not possible because of bleaching. Time lapse for Alexa488-labeled NDC80 (including Alexa488-labeled CENP-OPQU for direct comparison) were recorded for 40 s (488 nm excitation, exposure 60 ms, 100 ms/frame). All experiments were done on a CELLR/TIRF microscope (Olympus) equipped with an ImageEM emCCD camera (Hamamatsu photonics) and a 100x 1.49NA objective.

**SNAP-CENP-C pull-down experiments**

CENP-C\(^{1-544}\)-SNAP was covalently labeled with biotinylated benzylguanin (“Snap-biotin” reagent, New England Biolabs) according to manufacturer’s protocols. In a typical assay, 20 μl of streptavidin (STV)-coated beads (Pierce Streptavidin UltraLink Resin, Thermo Scientific) were used, per sample, and washed two times with 300 μl bead buffer (10 mM Hapes pH 7.5, 300 mM NaCl, 5% glycerol, 2 mM TCEP and 0.05% Triton X-100). The beads were re-suspended in 25 μl solution containing the proteins of interest at 2 μM and the mixture was incubated for 10 min on ice. To remove unbound materials from the beads, they were washed two times with 200 μl bead buffer. Samples were boiled in SDS loading buffer and subsequently analyzed by western blot. The following antibodies were used: CENP-P (Mouse monoclonal ABCAM ab66058, 1:1000), CENP-O (Mouse monoclonal ABCAM ab57539, 1:1000), CENP-R (Mouse monoclonal ABCAM ab57098, 1:1000), CENP-HK (rabbit polyclonal antibody SI0930 raised against the full-length human CENP-HK complex; 1:1000 (Klare et al., 2015)), CENP-N (rabbit polyclonal antibody SI0930 raised against CENP-N1-212 peptide; 1:1000), CENP-C (rabbit polyclonal antibody SI410 raised against CENP-C23-410 peptide; 1:1000; (Trazzi et al., 2009)). Secondary antibodies were anti-mouse, and anti-rabbit (Amersham, part of GE Healthcare) affinity purified with horseradish peroxidase conjugate (working dilution 1:1000).

**Cell culture and transfection**

U2OS cells, a gift from A. Bird (MPI-Dortmund, Germany), were grown in DMEM (PAN Biotech, Aidenbach, Germany) supplemented with 10% FBS (Clontech, part of Takara Bio group, Shiga, Japan), penicillin and streptomycin (GIBCO, Carlsbad, CA), and 2 mM L-glutamine (PAN Biotech).

FlpIn T-REx HeLa cells used to generate stable doxycycline-inducible cell lines were a gift from SS Taylor (University of Manchester, Manchester, England, UK). Flp-In T-REx host cell lines were maintained in DMEM (PAN Biotech, Aidenbach, Germany) with 10% tetracycline-free FBS (Clontech) supplemented with 50 μg/ml Zeocin (Invitrogen) and 2 mM L-glutamine (PAN Biotech). Flp-In T-REx HeLa expression cell lines were generated as previously described (Krenn et al., 2012). Gene expression was induced by addition of 0.2–0.5 μg/ml doxycycline (Sigma, St. Louis, MO) for 48 to 72 hr.

Proteins were depleted by siRNA, transfected into cells using HiPerFect transfection reagent (Qiagen) as per the manufactures instructions. Cells were treated with CENP-O siRNA (Dharmacon; 5'-UAGGAGACACAGCAUAAU-3') or CENP-P siRNA (Dharmacon SMARTpool; 5'-GUUGCAAGAGAAAACAUA-3', 5'-AGUCAGUUGUUUGAGGAUA-3', 5'-UAGUUCGUAAGGCGACGCUUA-3', and 5'-CCUAAGUGCUAAUCGAU-3') for 48 hr. While treatments of CENP-O siRNA (Dharmacon SMARTpool; 5'-GAGUUAAGUCUGGAAUA-3', 5'-AUGGAGAACGAGCAGA-3', 5'-AACAAGCAGACUAACUA-3', 5'-UGUCAGAGAAUAAAGGUU-3', and 5'-GUGCAAGAGAGAACAUA-3'), CENP-R (ITGB3BP, Dharmacon SMARTpool; 5'-GAAGUUGGAUGGUCUGU-3', 5'-UGACGCUAGAAGAUCUU-3', 5'-UAAGUAGUACUGCUUU-3', and 5'-GAAUAAGAUCUGGCUUA-3'), CENP-H (Dharmacon; 5'-UAGUGUCUGCUAAGAA-3'), CENP-L (Dharmacon; 5'-UUUAUGAGCCGACCAAGAAU-3'), or CENP-N (Dharmacon SMARTpool; 5'-CUACCCUGUGUUGUUA-3', 5'-GUUCAGACCUUCUCAUC-3', 5'-AUACACCGCUUCUGGGCUA-3', and 5'-ACACAAAGCCAAACCAAGUA-3') were for 72 h.

**Immunofluorescence**

FlpIn T-REx HeLa cells were grown on coverslips precoated with poly-D-Lysine (Millipore, 15 μg/ml). For co-localization experiments, FlpIn T-REx HeLa cells expressing full length GFP tagged CENP-R were synchronized overnight, 32 h or 56 h after siRNA transfection, in RO-3306 (Calbiochem) then released into 3.3 mM nocodazole (Sigma–Aldrich) for 2-3 h before fixation. For monopolar spindle recovery experiments U2OS cells were treated overnight in 5 mM (+)-S-Trityl-L-Cysteine (STLC, Sigma-Aldrich), then released and fixed after 3 h. To determine how CENP-O F158G and CENP-P F116G localize in metaphase, cells were fixed following their respective 48 h siRNA treatment. To investigate CENP-OPQUR recruitment following CENP-H, -L, or -N siRNA treatment cells were synchronized using 330 mM nocodazole for 15 h, 56 h after siRNA transfection. Cells were fixed as described (De Antoni et al., 2012). Alternatively, cells were fixed using 4% paraformaldehyde, and permeabilised using 0.25% Triton X-100. Cells were stained for GFP (Goat polyclonal, 1:500 (Poser et al., 2008) or GFP-Boost, Chromotec gba-488, 1:400), CENP-O (Rabbit polyclonal, raised against full length CENP-OP complex, 1:500), CENP-H (Goat, raised against full length CENP-OP complex, 1:500), CENP-HK (rabbit polyclonal antibody SI0930 raised against the full-length human CENP-HK complex; 1:1000; CREST/anti-centromere antibodies (Antibodies, Inc., Davis, CA, 1:100), CENP-A (Rabbit, Ossolengo, 1:500 or Mouse, Gene Tex GTX13939, 1:500) diluted in 5% boyled donkey serum in PHEM (Pipes, Hespis, EGTA, and MgCl2) for 2 h (PFA fixation) or over night (PHEM fixation) (De Antoni et al., 2012).

Donkey anti-human and donkey anti-goat Alexa Fluor 647, donkey anti-mouse, donkey anti-rabbit, and donkey anti-goat rhodamine, donkey anti-mouse and donkey anti-goat Alexa Fluor 488, donkey anti-human, donkey anti-rabbit, and donkey anti-mouse Alexa Fluor 405 (Jackson ImmunoResearch Laboratories, Inc., West Grove, PA), as well as donkey anti-mouse and chicken anti-rab-
bit Alexa Fluor 647, and donkey anti-rabbit Alexa Fluor 488 (Invitrogen) were used as secondary antibodies. DNA was stained with 0.5 μg/ml DAPI (Serva), and coverslips were mounted with Mowiol mounting media (Calbiochem). Cells were imaged using either a 3i Marianas system or a DeltaVision Ellyte System. The spinning disk confocal device on the 3i Marianas system equipped with an Axio Observer Z1 microscope (Zeiss), a CSU-1X confocal scanner unit (Yokogawa Electric Corporation, Tokyo, Japan), Plan-Apochromat 63x or 100x/1.4NA Oil Objectives (Zeiss), and Orca Flash 4.0 sCMOS Camera (Hamamatsu). Images were acquired as z-sections at 0.2 μm. Images were converted into maximal intensity projections, exported, and converted into 8-bit. Quantification of kinetochore signals was performed on unmodified 16-bit z-series images using Imaris 7.3.4 32-bit software (Bitplane, Zurich, Switzerland). After background subtraction, all signals were normalized to CREST or CENP-A. Measurements were exported in Excel (Microsoft) and graphed with GraphPad Prism 6.0 (GraphPad Software, San Diego California USA). The DeltaVision Elite System (GE Healthcare, UK) is equipped with an IX-71 inverted microscope (Olympus, Japan), UPlanFLN 40x/1.3NA objective or a PLAPON 60x/1.42NA objective (Olympus) and a pco.edge sCMOS camera (PCO-TECH Inc., USA).

Live cell imaging

Cells were plated on an 8 well 15 μ-Slide (Ibidi, Martinsried, Germany). CENP-P was depleted as previously described for 48 h prior to imaging. For asynchronous cells, FlpIn T-REX HeLa cells were transferred into CO2 Independent Medium (Gibco) 16 h before time-lapse. Two hours before imaging SiR-Hoechst DNA dye (Spirochrome) was added. Time-lapse demonstrating recovery from nocodazole treatment utilized U2OS cells drugged overnight with 330 nM nocodazole in CO2 Independent Medium (Gibco), SiR-Hoechst DNA dye (Spirochrome) was added into the nocodazole containing media 2 h before imaging. Cells were released from nocodazole by washing three times with PBS and then placed in CO2 Independent Media (Gibco) containing SiR-Hoechst DNA dye (Spirochrome). Where indicated, 0.5 μM Reversine was added to cells after release. Cells were imaged every 2 min for 12 h in a heated chamber (37°C) with a DeltaVision Elite System. Images were acquired as Z-sections (using the softWoRx software from DeltaVision) and converted into maximal intensity projections TIFF files for illustrative purposes.

Immunoprecipitation and immunoblotting

To generate mitotic populations for immunoprecipitation experiments, cells were treated with 330 nM nocodazole for 16 h. Mitotic cells were then harvested by mitotic shake off and lysed in lysis buffer (25 mM Tris pH 7.5, 100 mM NaCl, 5 mM MgCl, 10% Glycerol, 0.2% NP-40, 1 mM NaF, Benzonase (Sigma), supplemented with protease inhibitor cocktail (Serva, Heidelberg, Germany) and PhosSTOP phosphatase inhibitors (Roche)). Extracts were precleared using protein A-Sepharose (CL-4B; GE Healthcare) for 1 h at 4°C. Subsequently, extracts were incubated with GFP-Traps (ChromoTek, Martinsried, Germany; 2 μg/ml of extract) for 2 h at 4°C. Immunoprecipitates were washed with wash buffer (25 mM Tris pH 7.5, 100 mM NaCl, 5 mM MgCl, 10% Glycerol, supplemented with protease inhibitor cocktail [Serva, Heidelberg, Germany] and PhosSTOP phosphatase inhibitors [Roche]). To elute the proteins beads were incubated with 0.1 M glycine pH 2.0 for 10 min, 1 M Tris pH 9.2 was then added to neutralize eluates. Sample buffer was added, samples boiled and analyzed by SDS-PAGE and Western blotting using 14% tricine gels.

The following antibodies were used: anti-GFP (in house made rabbit polyclonal antibody; 1:1,000), CENP-OP (Rabbit polyclonal, raised against full length CENP-OP complex, 1:1,000), CENP-QU (Goat, raised against full length CENP-QU complex, 1:1,000), CENP-HK (rabbit polyclonal antibody SI0930 raised against the full-length human CENP-HK complex; 1:1,000 (Klare et al., 2015)), anti-Tubulin (mouse monoclonal; Sigma; 1:8000). Secondary antibodies were anti-mouse, anti-goat, and anti-rabbit (Amersham, part of GE Healthcare) affinity purified with horseradish peroxidase conjugate (working dilution 1:10000). After incubation with ECL Western blotting system (GE Healthcare), images were acquired using a BioRAD chemiDoc MP Imaging System (BioRAD). Images were acquired using Image Lab software Version 5.2 (BioRAD). Images were adjusted using the image lab software then exported in 8-bit tiff format for publication.

Tail-swap experiment

A cDNA encoding full-length, siRNA protected CENP-QNDC80(1-80) was ordered from GeneArt (Thermo Fisher) and subcloned into pMC273 using EcoRI and ScaI sites (replacing wild-type CENP-Q) to create CENP-QNDC80(1-80)-eGFP (pMC614). Correct insertion A cDNA encoding full-length, siRNA protected CENP-QNDC80(1-80) was ordered from GeneArt (Thermo Fisher) and subcloned into pMC273 using EcoRI and ScaI sites (replacing wild-type CENP-Q) to create CENP-QNDC80(1-80)-eGFP (pMC614). Correct insertion
LLC) equipped with a DAPI, fluorescein isothiocyanate (FITC), Rhodamine or Texas Red, CY5 filter set (Chroma), solid state light source and a CoolSNAP HQ camera (Roper Scientific). Image stacks were deconvolved using SoftWorx (Applied Precision, LLC). Fluorescence-intensity measurements were taken manually using SoftWorx and data visualized in R or Excel (Microsoft). Figures were prepared in Illustrator (Adobe). CENP-Q and NDC80 tail disorder predictions were generated using PrDOS (Ishida and Kinoshita, 2007) with a 5% false positive rate.

**QUANTIFICATION AND STATISTICAL ANALYSIS**

Statistical analyses are described in the Figure legends and in the Method Details.

**DATA AND SOFTWARE AVAILABILITY**

The data have been uploaded on the Mendeley server at https://doi.org/10.17632/yv552m8s98.1.

Reconstitution of a 26-subunit human kinetochore reveals cooperative microtubule binding by CENP-OPQUR and NDC80

by Marion E. Pesenti et al.

Including

Supplemental Figures S1 to S7, Table S1, and Movie S1, and their legends
Figure S1. Reconstitution and characterization of the human CENP-OPQUR complex; Related to Figure 1

A-B) Elution profiles and corresponding SDS-PAGE of recombinant CENP-OP and CENP-QU complexes. C) Elution profiles and SDS-PAGE analysis of a stoichiometric mixture of CENP-OP (blue) and CENP-QU (red) resulting in the formation of the four subunits complex CENP-OPQU (black). D) Elution profiles and corresponding SDS-PAGE of recombinant CENP-OPQU obtained by co-expression. E) Sedimentation velocity AUC demonstrated that each CENP-OPQUR complex and sub-complexes contained single copies of each subunit. CENP-R when expressed in isolation forms a tetramer. F) Elution profile and corresponding SDS-PAGE of recombinant CENP-R. I) Elution profile and corresponding SDS-PAGE of recombinant CENP-OPQUR obtained by co-expression in insect cells. G-H) Elution profiles and SDS-PAGE analysis of stoichiometric mixtures of CENP-R and CENP-OP (in G) or CENP-QU (in H). No strong direct interaction of isolated CENP-R with either CENP-OP or CENP-QU was observed. Note that the gel illustrating the elution of CENP-R (middle) in panels G and H has been intentionally duplicated to visualize elution shifts (or lack thereof). J) Insect cell co-expression of CENP-R with CENP-OPQU (positive control) or CENP-QU results in the identification of CENP-R in the elution fraction after purification with His-CENP-PO and/or His-CENP-QU. When co-expressed, CENP-R does not bind CENP-OP. Thus, CENP-R interacts predominantly with CENP-QU subunit. (T, Total cleared lysate; SN, Soluble faction; FT, Flow Through; E, Elution). K) Representative images show the localization of recombinant CENP-OPQUR labeled with Alexa488 (green) in mitotic cells after electroporation into interphase cells. CREST syndrome autoantibodies identify kinetochores. Scale bar = 5 µm. L) Elution profiles and SDS-PAGE analysis of a stoichiometric mixture of CENP-OP (blue) and CENP-Q68C-U (red) resulting in the formation of the four subunits complex CENP-OPQ68C-U (black).
Figure S2. Localization dependencies; Related to Figure 2

A) Western blot showing the depletion of CENP-H in each of the GFP-CENP-OPQU R HeLa FlpIn TRex stable cell lines. B-E) Representative images of HeLa FlpIn TRex cells stably expressing GFP-CENP-O (B), GFP-CENP-P (C), GFP-CENP-R (D), and GFP-CENP-U (E), where CENP-H, CENP-L, and CENP-N have been depleted by RNAi. CENP-O, -P, -U, and -R are all lost from the kinetochore in the absence of CENP-H, -L, or -N. The CENP-HK complex is also lost from kinetochores during the aforementioned RNAi depletions. Quantification of the GFP-CENP-OPUR proteins after the indicated depletion are shown to the right of their respective images in green, CENP-HK is shown in red. **p ≤ 0.01. Graph shows results from one of three independent experiments, a minimum of 158 (CENP-O), 113 (CENP-P), 54 (CENP-U), or 124 (CENP-R) kinetochores were quantified for the cell line indicated in brackets. All scale bars = 5 µm. F) Assessment of depletion levels for the RNAi experiments. Western blot showing the depletion of CENP-O, -P, -Q, or -R from FlpIn TRex cells stabling expressing GFP-CENP-R. G) Co-localization studies were carried out by depleting CENP-O, CENP-P, CENP-Q, or CENP-R, using RNAi, from HeLa FlpIn TRex cells stabling expressing GFP-CENP-R. Cells were stained with antibodies targeting CENP-OP, CENP-QU, and Nsl1. Insets identify kinetochores. Scale bar = 5 µm. H) Quantification of the co-localization of CENP-OP, CENP-QU, and GFP-CENP-R following depletion of CENP-O, CENP-P, CENP-Q, and CENP-R in HeLa FlpIn TRex cells. The graph shows a minimum of 276 kinetochores from at least three technical replicas of the experiment. I) Mitotic index of cells depleted of CENP-O, CENP-P, CENP-Q, CENP-R, or left untreated. Depletion of any CENP-O complex protein significantly increased the mitotic index as compared to the untreated control, indicating that CENP-OPQUR has a role in mitotic progression. **p ≤ 0.01.
**Figure S3.** RWD domains in CENP-OP and Knl1 have similar interaction modes with their targets; Related to Figure 2

A-C) Elution profiles and subsequent SDS-PAGE of the recombinant CENP-C¹⁻⁵⁴⁴, CENP-HIKM, and CENP-LN complexes. D-E) Cartoon models comparing the RWD domains of Knl1 (residues 2106-2311; PDB access number 4NF9) and Ctf19 (residues 96–269; PDB access number 3ZXU). Tyr2125 of Knl1 is the residue responsible for the binding of Nsl1. Phe138 of Ctf19 (F116 in human CENP-P) is conserved and its position is close related to that of Knl1 Tyr2125. F) Sequence alignment of CENP-P and Ctf19 from the indicated species in the region containing Phe116. G) Pull-down assays using SNAP-CENP-C¹⁻⁵⁴⁴ bait. CENP-OPᵮ¹¹₆G (2 µM) fails to bind to immobilized CENP-CHIKMLN, and further prevents binding of CENP-QU (also at 2 µM). The experiment shown is representative of at least 3 repeats. H) Immunoprecipitation (IP) assays were carried out using cell lines that stably expressed GFP-CENP-P or its respective RWD domain mutants GFP-CENP-Pᵮ¹¹₆G. The mutation of the CENP-P RWD domain disrupted its interaction with CENP-HK and CENP-QU, while maintaining its binding to CENP-N. Lysates from cells expressing GFP alone were used as a control and did not interact with any of the aforementioned proteins.
Pesenti et al
Figure S3
Figure S4. Analytical SEC and SDS-PAGE analysis of stoichiometric mixtures of CENP-OPQUR with different kinetochore subunits; Related to Figures 3 and 6

A-B) The omission of CENP-LN or CENP-HIKM prevents the interaction of CENP-OPQUR with CENP-HIKM and CENP-LN, respectively. C-F) CENP-OPQUR cannot form a complex with any other KT subunits if it is not incorporated in the CENP-HIKMLNOPQUR complex. Note that the gels illustrating the elution of CENP-OPQUR in panels A-B, C-D, or E-F have been intentionally duplicated to visualize elution shifts (or lack thereof) when mixing with potential binding partners. The same is true of the gel illustrating the elution of the mixture containing CENP-OPQUR, CENP-C^{1-344}, MIS12C, and NDC80C, which was intentionally duplicated in panels E-F (bottom).
Figure S5. CENP-HIKMLNOPQUR complex and the rKT26. Related to Figures 3 and 4.

A) Primary data and fitting residuals for the AUC run in Figure 3C. B-C) SDS-PAGE analysis of the fractions collected after GraFix procedure of the CENP-HIKMLNOPQUR complex in absence (A) and presence (B) of glutaraldehyde (Kastner et al., 2008). In fraction 12, all the 11 proteins are present (A) and form a slow migrating band when cross-linked (B). D) Fraction 12 of the cross-linked sample was analyzed by Western blotting and shown to contain the 11 subunits. E-F) Electron densities of CENP-HIKM (green) and CENP-OPQUR (violet) were manually fitted into CENP-HIKMLNOPQUR. Inspection of the volume reveals that the sub-complexes do not occupy the full volume, leaving additional space that was attributed to the LN sub-complex (see also Figure 3E-H). The difference map was created using Chimera and filtered to 20 Å resolution. For an additional visualization see Movie 1. Scale bar = 10 nm. G-J) Elution profiles and SDS-PAGE of recombinant subunits of human kinetochore proteins used for the assembly of the rKT26. Every subunit or complex elutes in a single peak with a retention volume larger than that of rKT26.
Pesenti et al Figure S5
**Figure S6. CENP-OPQUR complex binds microtubules via CENP-QU and CENP-R subunits; Related to Figures 3 and 5**

**A)** Representative electron micrograph area of the negatively stained CENP-OPQU complex. Scale bar = 100 nm (10 nm, enlarged). The resolution was estimated by the Fourier shell correlation (FSC) 0.5 criterion to be ~23 Å. A Collection of class averages of the CENP-OPQU complex derived from a data set of 4745 single particles. Selected Reprojections of the 3D reconstruction paired with their corresponding class averages. Scale bar = 10 nm. **B)** Representative electron micrograph area of the negatively stained CENP-OPQUR complex. Scale bar = 10 nm. The resolution was estimated by the Fourier shell correlation (FSC) 0.5 criterion to be ~23 Å. A Collection of class averages of the CENP-OPQUR complex derived from a data set of 3260 single particles. Selected Reprojections of the 3D reconstruction paired with their corresponding class averages. Scale bar = 10 nm. **C)** Representative SDS-PAGE of microtubule co-sedimentation assays of 1 µM CENP-OP, CENP-QU, CENP-R, CENP-OPQU, CENP-OPQUR, CENP-OPQ68-UR, and CENP-OPQ68-CUR with 10 µM taxol-stabilized microtubules. P, pellet fraction; S, soluble fraction. A subset of panels from this figure are additionally shown in Figure 5A. **D)** Quantification of experiments in C. Error bars are standard deviations calculated from three technical replicas. **E)** Representative electron micrographs of negatively stained microtubules bundled upon exposure to increasing concentration of CENP-OPQU complex. Scale bar = 40 nm. **F)** Additional representatives electron micrographs of negative-stained Taxol-stabilized microtubules in presence of CENP-OPQUR. The outline of the complex, recognizable on the microtubule surface, suggests that the microtubule-binding moiety is in the base domain. Scale bar = 20 nm. **G)** Representative electron micrograph area of the negatively stained CENP-HIKMLNOPQUR complex. A Collection of selected reprojections of the 3D reconstruction of the CENP-HIKMLNOPQUR complex paired with their corresponding class averages derived from a data set of 10515 single particles. Scale bar = 20 nm. The resolution was estimated by the Fourier shell correlation (FSC) 0.5 criterion to be ~22 Å.
Figure S7. SEC analysis demonstrating interaction of CENP-OPQ<sup>68-68</sup>-CUR mutant with rKT21 and various alignment and checkpoint assays; Related to Figures 6 and 7

A) Analytical SEC and SDS-PAGE analysis of stoichiometric mixtures of CENP-OPQ<sup>68-68</sup>-CUR with CENP-11 subunits demonstrating complex assembly. In panels B-D, we demonstrate that depletion of CENP-OPQUR subunits is associated with a variety of spindle assembly and chromosome alignment problems, with delayed mitotic exit and frequent lagging chromosomes at anaphase, phenotypes that are strongly exacerbated during recovery from spindle damage (Bancroft et al., 2015; Hori et al., 2008b; Hua et al., 2011; McAinsh et al., 2006; McClelland et al., 2007; Minoshima et al., 2005; Toso et al., 2009). For reasons that remain unclear, penetrance of these effects varies considerably in different cell and organismal models (Kagawa et al., 2014; McKinley et al., 2015). After depleting CENP-P by RNAi, we monitored the timing of mitotic progression by time-lapse video microscopy in HeLa cells. We show that addition of Reversine, an inhibitor of the spindle assembly checkpoint kinase Mps1 (Santaguida et al., 2010), promoted very rapid anaphase in CENP-P depleted cells, indicating that the mitotic delay is caused by checkpoint activation (panel B). In an established chromosome bi-orientation assay, in which HeLa cells were first treated with STLC (an inhibitor of the Eg5 kinesin) to prevent spindle bipolarization, and then allowed to bipolarize by STLC washout before fixation, CENP-P-depleted cells contained a high proportion of chromosomes that had failed to bi-orient, indicating that the CENP-OPQUR contributes to chromosome bi-orientation (panel C). Finally, the chromosome alignment defects caused by depletion of CENP-P and CENP-Q were at least partially rescued after electroporation of recombinant CENP-OPQUR complex, but not of CENP-OPQ<sup>68-68</sup>-CUR complex (panel D). B) Additional immunofluorescence images of the tail-swap rescue experiment described and quantified in Figure 7B-E. Here, we chose two cells in the same field of view that had either received (cell 1) or not received (cell 2) the CENP-Q-eGFP rescue construct. Note kinetochore localization of CENP-E in cells expressing CENP-Q-eGFP and lack thereof in non-transfected cells. Scale bar 5 μm. C) As in B, but showing a field of view from cells that had (cell 1) or had not (cell 2) received the CENP-Q<sup>NDC80(1-80)</sup>-eGFP transgene. D) The CENP-OPQUR complex is required for recovery from nocodazole. Quantification of time-lapse microscopy experiments on U2OS cells, either untreated, depleted of CENP-P, or depleted of CENP-P and treated with 0.5 μM
Reversine, progressing to anaphase after release (time 0) from a 16-hour nocodazole (330 nM) treatment. E) Recovery from monopolarity is impaired in absence of the CENP-OPQUR complex. Quantification of experiments in which U2OS cells were synchronized for 16 hours with 5 µM STLC, an Eg5 inhibitor, then released in inhibitor-free medium containing MG132 and fixed after 3 h. Loss of the CENP-OPQUR complex resulted in a large fraction of cells with misaligned chromosomes, indicative of error correction problems. F) Cells depleted for CENP-Q/P and electroporated either with Alexa-488 labeled CENP-OPQWTUR or CENP-OPQ68-4UR. Following synchronisation with STLC treatment, cells were released MG132 containing medium for 150 minutes before being prepared for immunofluorescence analysis and scored for the presence of uncongressed chromosomes. When compared with CENP-OPQWTUR, electroporation of CENP-OPQ68-4UR results in a larger fraction of cells with uncongressed chromosomes.
