We have developed a rigorous quantum model of spontaneous parametric down-conversion in a nonlinear 1D photonic-band-gap structure based upon expansion of the field into monochromatic plane waves. The model provides a two-photon amplitude of a created photon pair. The spectra of the signal and idler fields, their intensity profiles in the time domain, as well as the coincidence-count interference pattern in a Hong-Ou-Mandel interferometer are determined both for cw and pulsed pumping regimes in terms of the two-photon amplitude. A broad range of parameters characterizing the emitted down-converted fields can be used. As an example, a structure composed of 49 layers of GaN/AlN is analyzed as a suitable source of photon pairs having high efficiency.

PACS numbers: 42.50.Dv

I. INTRODUCTION

More than 20 years ago, Hong, Ou, and Mandel showed experimentally that mutually strongly quantum correlated (entangled) photon pairs can be emitted in the nonlinear process of parametric down-conversion \cite{1,2} at the single-photon level. For the occurrence of entangled photon pairs, the spontaneous character of the process is important. Entanglement of two photons comprising a photon pair might occur for various physical quantities like frequencies, emission angles (wave-vectors), or polarizations. Perhaps most interestingly, entangled photon pairs manifest themselves in time domain, where both photons are detected within a relatively narrow time window. This is a direct consequence of the ‘point’ character of the emission of a photon pair in the time domain. The width of the time window characterized by an entanglement time is typically on the order of several hundreds of fs, and is experimentally observable using Hong-Ou-Mandel interferometer.

In the time that has intervened since the original predictions, entangled photon pairs have been used for numerous experiments demonstrating both fundamental aspects of their physical properties \cite{3} and their potential for applications. These also include tests of Bell inequalities \cite{4}, quantum teleportation \cite{5}, the generation of Greenberger-Horne-Zeilinger states \cite{6}, or quantum computation \cite{7} that can exploit photon pairs. Quantum cryptography with photon pairs \cite{8} may be considered the most important application. We mention that applications to metrology have also been suggested \cite{9}.

Most researchers in the field have focused their attention for the most part on bulk nonlinear crystals, pumped by intense laser beams in type I and type II configurations. Bright sources of polarization-entangled photon pairs have been fabricated using two nonlinear type I crystals, mutually rotated by 90 degrees \cite{10,11}. The nonlinear processes in an optical cavity have also been used to enhance the photon-pair generation rate \cite{12}. In addition, periodically-poled materials may be used to increase the photon-pair generation rate in materials where phase matching is not naturally available \cite{13}. At present, even sources of photon pairs pumped by laser diodes have been developed \cite{14}.

On the fabrication front, techniques of structures composed of nonlinear thin layers (of width of several tens or hundreds of nm) have developed to the point that useful structures with pre-defined properties may be achieved rather easily \cite{15}. These nonlinear photonic-band-gap structures \cite{16,17,18,19} are very promising as sources of photon pairs, as has recently been shown in \cite{20,21}. Despite the small amount of nonlinear material embedded inside them, they can generate photon pairs with relatively high efficiency thanks to the constructive interference that involves both the pump and the down-converted fields, their spatial inhomogeneity notwithstanding. The enhancement of the photon-pair generation rate has been predicted to be several hundreds and even thousands of times larger than photon-pair generation rates in nonlinear, bulk materials \cite{21}. Moreover, the spectral and spatial characteristics of the down-converted fields depend on details of the structure, a fact that might be used to control the process, at least to some extent. For example, photon pairs with very narrow spectra may be obtained from suitable structures. We note that along

the same vein, four-wave mixing in photonic-band-gap nonlinear fibers is also promising as a modern source of photon pairs [22, 23].

In this paper, we present a quantum model of photon-pair emission in a nonlinear, one-dimensional photonic-band-gap structure, based upon a perturbative solution of the Schrödinger equation. This model extends those developed for bulk nonlinear materials in [24, 25, 26, 27]. It has been shown in [21] that this approach is compatible with models based on methods of classical nonlinear optics (multiple-scale spatial and temporal expansion methods) with a specific kind of stochastic averaging concerning emitted spectra. The quantum model, however, provides a complete description of the nonlinear process.

The paper is organized as follows. In Sec. II, the model is presented in three steps. Description of a quantum field in a layered medium in Subsec. IIA is followed by the description of nonlinear quantum interactions in Subsec. IIB. In Subsec. IIC measurable characteristics of the generated down-converted fields are determined. The behavior of physical quantities characterizing a photon pair are discussed in Sec. III, both for cw and pulsed pumping regimes. Sec. IV contains our conclusions.

II. DESCRIPTION OF SPONTANEOUS PARAMETRIC DOWN-CONVERSION IN A ONE-DIMENSIONAL, NONLINEAR PHOTONIC-BAND-GAP STRUCTURE

We consider a stack of \( N \) nonlinear layers in which spontaneous parametric down-conversion may occur. A sketch of the system is shown in Fig. 1. The \( l \)th layer begins at \( z = z_{l-1} \) and ends at \( z = z_l \); its length is denoted as \( L_l \). Linear indices of refraction of pump, signal, and idler fields in the \( l \)th layer are denoted as \( n_{p}^{(l)} \), \( n_{s}^{(l)} \), and \( n_{i}^{(l)} \), respectively. Symbols \( n_{s}^{(0)} \), \( n_{i}^{(0)} \), and \( n_{p}^{(0)} (n_{s}^{(N+1)}, n_{i}^{(N+1)}, \text{and} n_{p}^{(N+1)}) \) mean indices of refraction in front of (beyond) the sample. The symbol \( d^{(l)} \) is used for the nonlinear tensor of \( l \)th layer; symbols \( k_{p}^{(l)} \), \( k_{s}^{(l)} \), and \( k_{i}^{(l)} \) stand for pump-, signal-, and idler-field wave-vectors in the \( l \)th layer.

A. Optical fields in a one-dimensional photonic-band-gap structure

The structure is pumped by a classical strong pump field that propagates under the angle \( \vartheta_p \) with respect to \( z \) axis (see Fig. 2). Its wave-vector \( k_p \) lies in the \( yz \) plane, whereas its electric-field amplitude \( E_{pp} \) is perpendicular to the wave-vector \( k_p \). The pump-field positive-frequency electric-field amplitude at the input of the structure at \( z = z_0 \) is denoted as \( E_{pp}^{(+)}(z_0, t) \) and can be conveniently described using a positive-frequency electric-field amplitudes spectrum \( E_{pp}^{(+)}(z_0, \omega_p) \) determined as follows:

\[
E_{pp}^{(+)}(z_0, \omega_p) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} dt E_{pp}^{(+)}(z_0, t) \exp(i\omega_p t) \quad (1)
\]

If we assume a Gaussian time profile and a linear polarization of the incident electric-field amplitude \( E_{pp} \) in the direction rotated by an angle \( \varphi_p \) with respect to an incident TE-wave polarization direction \( E_{TE} \), then the incident TM wave polarization direction \( E_{TM} = \sqrt{2} E_{TM} \) denotes an incident TM wave polarization direction, see Fig. 2 we have:

\[
E_{pp}^{(+)}(z_0, t) = [e_{pp, TE} \cos(\varphi_p) + e_{pp, TM} \sin(\varphi_p)] \\
\times \xi_p \exp \left(-\frac{1 + i a_p t^2}{\tau_p^2}\right) \exp(-i \omega_p t),
\]

where \( \omega_p \) is the pump-pulse amplitude, \( \tau_p \) pulse duration, \( \omega_p \) central frequency, and \( a_p \) denotes a chirp parameter of the pulse. The spectrum \( E_{pp}^{(+)}(z_0, \omega_p) \) is determined by Eq. (1) is given as:

\[
E_{pp}^{(+)}(z_0, \omega_p) = [e_{pp, TE} \cos(\varphi_p) + e_{pp, TM} \sin(\varphi_p)]
\]
\[ \times \xi_p \frac{\tau_p}{\sqrt{2(1 + i\alpha_p)}} \exp \left( -\frac{\tau_p^2}{4(1 + i\alpha_p)}(\omega_p - \omega_{p,0}^0)^2 \right) = E^{(+)\omega}_E(z_0, \omega_p) + E^{(+)\omega}_M(z_0, \omega_p). \quad (3) \]

On the other hand, the following spectrum corresponds to cw pumping:

\[ E^{(+\omega)}_{p,E}(z_0, \omega_p) = [e_{p,E,0} \cos(\varphi_p) + e_{p,M,0} \sin(\varphi_p)] \]

\[ \times \xi_p \delta(\omega_p - \omega_{p,0}^0); \quad (4) \]

\( \delta \) means a Dirac delta function.

The pump field incident on the structure is scattered at each boundary inside the structure, so as to achieve a certain profile along the \( z \) axis, provided that the non-linear interaction does not lead to pump-field depletion. Scattering of the pump field is conveniently described using its decomposition into monochromatic waves. The positive-frequency electric-field amplitude \( E^{(+)\omega}_{p,0}(z, \omega_p) \) of a monochromatic component at frequency \( \omega_p \) with polarization \( \alpha \) (\( \alpha = \text{TE}, \text{TM} \)) can be written as follows \[23,24\]:

\[ E^{(+\omega)}_{p,0}(z, \omega_p) = \text{rect}_{-\infty, z_0}(z) \times \left[ A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(ik_{+}^{(0)}(z, z_0)) \right. \]

\[ + A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(-ik_{+}^{(0)}(z, z_0)) \]

\[ + \sum_{l=1}^{N} \text{rect}_{z_l, z_{l-1}}(z) \times \left[ A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(ik_{+}^{(0)}(z, z_{l-1})) \right. \]

\[ + A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(-ik_{+}^{(0)}(z, z_{l-1})) \]

\[ + \text{rect}_{z_{N}, \infty}(z) \times \left[ A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(ik_{+}^{(0)}(z, z_{N})) \right. \]

\[ + A^{(+)\omega}_{p,0}(\omega_p) e^{(+)\omega}_{p,0}(\omega_p) \exp(-ik_{+}^{(0)}(z, z_{N})) \right] ; \quad \alpha = \text{TE}, \text{TM}; \quad (5) \]

the function \( \text{rect}_{z_{a}, z_{b}}(z) \) equals one for \( z_a \leq z \leq z_b \) and is zero otherwise. Polarization vectors of \( \alpha \)-waves in \( l \)th layer are denoted as \( e_{p,0}^{(+)\omega} \) and \( e_{p,0}^{(-)\omega} \) for forward- and backward-propagating fields with respect to \( z \) axis, respectively, and they are frequency dependent. The symbol \( k_{\omega}^{(l)} \) denotes a \( z \) component of the pump-field wavevector \( k_{p}^{(l)} \) in \( l \)th layer and is determined by the expression

\[ k_{p,z}^{(l)} = k_{p}^{(l)} \cos(\theta_{p}^{(l)}), \quad (6) \]

where the wave-vector \( k_{p}^{(l)} \) propagates in the \( l \)th layer under the angle \( \theta_{p}^{(l)} \) with respect to \( z \) axis. The angles \( \theta_{p}^{(l)} \) fulfill the Snell law at the boundaries, i.e.

\[ n_{p}^{(l)} \sin(\theta_{p}^{(l)}) = n_{p}^{(l+1)} \sin(\theta_{p}^{(l+1)}), \quad l = 0, \ldots, N; \quad (7) \]

\( \theta_{p}^{(0)} = \theta_{p} \).

The symbol \( A^{(0)\omega}_{p,\alpha}(\omega_p) \) is identified as an electric-field amplitude of the pump field at frequency \( \omega_p \) with polarization \( \alpha \) incident on the structure from the left-hand side, whereas the symbol \( A^{(+)\omega}_{p,\alpha}(\omega_p) \) describes an electric-field amplitude of the pump field at frequency \( \omega_p \) with polarization \( \alpha \) incident from the right-hand side.

The remaining amplitudes \( A^{(+)\omega}_{p,\alpha}(\omega_p) \) and \( A^{(0)\omega}_{p,\alpha}(\omega_p) \) are determined using relations at the boundaries and free-field propagation inside the layers:

\[ \begin{align*}
A^{(+)\omega}_{p,\alpha}(\omega_p) &= T^{(+)\omega}_{\alpha}(\omega_p) \left[ A^{(0)\omega}_{p,\alpha}(\omega_p) \right. \\
A^{(0)\omega}_{p,\alpha}(\omega_p) &= T^{(0)\omega}_{\alpha}(\omega_p) A^{(+)\omega}_{p,\alpha}(\omega_p),
\end{align*} \quad (8) \]

We note that the coefficients \( A^{(+)\omega}_{p,\alpha}(\omega_p) \) and \( A^{(0)\omega}_{p,\alpha}(\omega_p) \) for \( l = 1, \ldots, N \) describe the corresponding electric-field amplitudes at the beginning of \( l \)th layer.

Assuming TE and TM waves, the boundary transfer matrices \( T^{(+)\omega}_{\alpha}(\omega_p) \) and \( T^{(0)\omega}_{\alpha}(\omega_p) \) have the form:

\[ \begin{align*}
T^{(+)\omega}_{\alpha}(\omega_p) &= \\
&= \frac{1}{2} \begin{pmatrix} 1 + f^{(+)\omega}_{p,\alpha}(\omega_p) g^{(+)\omega}_{p,\alpha}(\omega_p) & 1 - f^{(+)\omega}_{p,\alpha}(\omega_p) g^{(+)\omega}_{p,\alpha}(\omega_p) \\
1 - f^{(+)\omega}_{p,\alpha}(\omega_p) g^{(+)\omega}_{p,\alpha}(\omega_p) & 1 + f^{(+)\omega}_{p,\alpha}(\omega_p) g^{(+)\omega}_{p,\alpha}(\omega_p) \end{pmatrix}, \\
T^{(0)\omega}_{\alpha}(\omega_p) &= \\
&= \frac{1}{2} \begin{pmatrix} f^{(+)\omega}_{p,\alpha}(\omega_p) + g^{(+)\omega}_{p,\alpha}(\omega_p) & f^{(+)\omega}_{p,\alpha}(\omega_p) - g^{(+)\omega}_{p,\alpha}(\omega_p) \\
f^{(+)\omega}_{p,\alpha}(\omega_p) - g^{(+)\omega}_{p,\alpha}(\omega_p) & f^{(+)\omega}_{p,\alpha}(\omega_p) + g^{(+)\omega}_{p,\alpha}(\omega_p) \end{pmatrix}, \quad (9)
\end{align*} \]

\( f_p^{(l)} = \cos(\theta_p^{(l)}) / \cos(\theta_p^{(l+1)}) \) and \( g_p^{(l)} = 1 / f_p^{(l)} \). The free-field propagation matrices \( T^{(+)\omega}_{\alpha}(\omega_p) \) can be written as:

\[ T^{(+)\omega}_{p,\alpha}(\omega_p) = \\
\begin{pmatrix} \exp(i k_{p,z}^{(l)} L_1) & 0 \\
0 & \exp(-i k_{p,z}^{(l)} L_1) \end{pmatrix}, \quad l = 1, \ldots, N. \quad (10) \]

The positive-frequency electric-field operators \( \hat{E}^{(+\omega)}_{m,z}(z,t) \) and \( \hat{E}^{(+)\omega}_{m}(z,t) \) for the signal and idler fields can be decomposed into TE- and TM-wave contributions \( \hat{E}^{(+)\omega}_{m,TE}(z,t) \), \( \hat{E}^{(+)\omega}_{m,TM}(z,t) \), \( \hat{E}^{(+)\omega}_{m,TE}(z,t) \), and \( \hat{E}^{(+)\omega}_{m,TM}(z,t) \) and expressed as follows \[24\]:

\[ \hat{E}^{(+)\omega}_{m,z}(z,t) = \sum_{\alpha = \text{TE, TM}} \int_{0}^{\infty} d\omega_m \sqrt{\frac{\hbar \omega_m}{4 \pi c_0 \varepsilon \mathcal{B}}} \]

\[ \times \left[ \hat{a}_{m,\alpha}(z, \omega_m) e_{m,\alpha}(z, \omega_m) + \hat{a}^\dagger_{m,\alpha}(z, \omega_m) e_{m,\alpha}(z, \omega_m) \right] \exp(-i \omega_m t) \]

\[ = \hat{E}^{(+)\omega}_{m,TE}(z,t) + \hat{E}^{(+)\omega}_{m,TM}(z,t) \]
The permittivity of vacuum is denoted as $\varepsilon_0$; $c$ means speed of light in vacuum, $\hbar$ is the reduced Planck constant, and $\mathcal{B}$ denotes the area of the transverse profile of a beam. The symbols $\mathbf{e}_{m,F,\alpha}(z,\omega_m)$ and $\mathbf{e}_{m,B,\alpha}(z,\omega_m)$ mean polarization vectors of mode $m$ of $\alpha$ wave propagating forward and backward with respect to the $z$ axis. Annihilation operators of signal $[\hat{a}_{F,\alpha}(z,\omega), \hat{a}_{B,\alpha}(z,\omega)]$ and idler $[\hat{a}_{i,\alpha}(z,\omega), \hat{a}_{i,\alpha}(z,\omega)]$ photons in $\alpha$ wave are introduced in Eq. (11) can be expressed in the same way as the pump-field amplitude $\mathbf{E}_{p,\alpha}(z,\omega_p)$:

$$\hat{a}_{m,F,\alpha}(z,\omega)\mathbf{e}_{m,F,\alpha}(z,\omega) + \hat{a}_{m,B,\alpha}(z,\omega)\mathbf{e}_{m,B,\alpha}(z,\omega) = \text{rect}_{-\infty,z_0}(z) \times$$

$$\times \left[ \hat{a}_{m,F,\alpha}(\omega)\mathbf{e}_{m,F,\alpha}(\omega) \exp(ik_{m,z}(z-z_0)) \right] + \hat{a}_{m,B,\alpha}(\omega)\mathbf{e}_{m,B,\alpha}(\omega) \exp(-ik_{m,z}(z-z_0)) +$$

$$+ \sum_{l=1}^{N} \text{rect}_{z_{l-1},z_{l}}(z) \times$$

$$\times \left[ \hat{a}_{m,F,\alpha}^{(l)}(\omega)\mathbf{e}_{m,F,\alpha}^{(l)}(\omega) \exp(ik_{m,z}^{(l)}(z-z_{l-1})) \right] + \hat{a}_{m,B,\alpha}^{(l)}(\omega)\mathbf{e}_{m,B,\alpha}^{(l)}(\omega) \exp(-ik_{m,z}^{(l)}(z-z_{l-1})) +$$

$$+ \text{rect}_{N,\infty}(z) \times$$

$$\times \left[ \hat{a}_{m,F,\alpha}^{(N+1)}(\omega)\mathbf{e}_{m,F,\alpha}^{(N+1)}(\omega) \exp(ik_{m,z}^{(N+1)}(z-z_N)) \right] + \hat{a}_{m,B,\alpha}^{(N+1)}(\omega)\mathbf{e}_{m,B,\alpha}^{(N+1)}(\omega) \exp(-ik_{m,z}^{(N+1)}(z-z_N)),$$

$$m = s, i; \quad \alpha = TE, TM. \quad (12)$$

The polarization vectors $\mathbf{e}_{m,F,\alpha}$ and $\mathbf{e}_{m,B,\alpha}$ give the polarization directions of mode $m$ with $\alpha$ wave in $l$th layer propagating forward and backward, respectively, whereas $k_{m,z}^{(l)}$ is a $z$ component of the wave vector $k_m^{(l)}$ of this mode:

$$k_{m,z}^{(l)} = k_m^{(l)} \cos(\vartheta_m^{(l)}), \quad m = s, i. \quad (13)$$

The angle $\vartheta_m^{(l)}$ characterizes the direction of propagation of mode $m$ with respect to the $z$ axis. The angles $\vartheta_m^{(l)}$ are given by the Snell law at the boundaries, i.e.

$$n_m^{(l)} \sin(\vartheta_m^{(l)}) = n_m^{(l+1)} \sin(\vartheta_m^{(l+1)}), \quad m = s, i; \quad l = 0, \ldots, N; \quad (14)$$

$\vartheta_m^{(0)} = \vartheta_m$, where $\vartheta_m$ stands for the angle of incidence of mode $m$.

The operators $\hat{a}_{m,F,\alpha}(\omega_m)$ and $\hat{a}_{m,B,\alpha}(\omega_m)$ obey the following commutation relations:

$$[\hat{a}_{m,F,\alpha}(\omega_m), \hat{a}_{m,F,\alpha}^{(l)}(\omega_m)] = 0, \quad [\hat{a}_{m,B,\alpha}(\omega_m), \hat{a}_{m,B,\alpha}^{(l)}(\omega_m)] = 0,$$

$$[\hat{a}_{m,F,\alpha}^{(l)}(\omega_m), \hat{a}_{m,B,\alpha}^{(l)}(\omega_m)] = \delta_{\alpha,\alpha'} \delta(\omega_m - \omega_m'), \quad m, m' = s, i.$$

The photonic-band-gap structure imposes the following relations among the operators $\hat{a}_{m,F,\alpha}(\omega_m)$ and $\hat{a}_{m,B,\alpha}(\omega_m)$ acting in $l$th layer:

$$\hat{a}_{m,F,\alpha}^{(l+1)}(\omega_m) = \tau_{m,\alpha}^{(l)}(\omega_m) \hat{a}_{m,F,\alpha}^{(l)}(\omega_m), \quad \hat{a}_{m,B,\alpha}^{(l+1)}(\omega_m) = \tau_{m,\alpha}^{(l)}(\omega_m) \hat{a}_{m,B,\alpha}^{(l)}(\omega_m), \quad \alpha = TE, TM; \quad l = 1, \ldots, N. \quad (15)$$

Transfer matrices $\tau_{m,\alpha}^{(l)}$ at the boundaries and free-field propagation matrices $\mathbf{T}_m^{(l)}$ for $m = s, i$ and $\alpha = TE, TM$ are defined in the same way as those given in Eqs. (9) and (10) for the pump-field amplitudes.

### B. Nonlinear interaction inside the photonic-band-gap structure

The Hamiltonian $\hat{H}(t)$ describing spontaneous parametric down-conversion in a nonlinear medium of volume $\mathcal{V}$ at time $t$ can be written as:

$$\hat{H}(t) = \varepsilon_0 \int_{\mathcal{V}} d\mathbf{r} \left[ \mathbf{E}_p^{(+)}(\mathbf{r}, t) \mathbf{E}_s^{(-)}(\mathbf{r}, t) \mathbf{E}_i^{(-)}(\mathbf{r}, t) + h.c. \right], \quad (17)$$

where $\mathbf{d}(\mathbf{r}) = [\mathbf{E}_p^{(+)}(\mathbf{r}, t) \mathbf{E}_s^{(-)}(\mathbf{r}, t) \mathbf{E}_i^{(-)}(\mathbf{r}, t) + h.c.]$. Decomposing the interacting fields into TE and TM waves, and using the inverse Fourier transformation in Eq. (17), we arrive at:

$$\hat{H}(t) = \frac{\varepsilon_0 \mathcal{B}}{\sqrt{2\pi}} \int_0^L dz \int_0^\infty \omega \int_0^\infty \omega_s \int_0^\infty \omega_i \sum_{\alpha,\beta,\gamma=TE, TM} d(z) \left[ \mathbf{E}_p^{(+)}(z, \omega_p) \mathbf{E}_s^{(-)}(z, \omega_s) \mathbf{E}_i^{(-)}(z, \omega_i) + h.c. \right]. \quad (18)$$

Integrations over the variables $x$ and $y$ in Eq. (17) impose conditions for $x$ and $y$ component of wave-vectors;
for $K_{s,x,\alpha} + k_{i,x} = 0$ is assumed] and $\delta(k_{s,y} + k_{i,y} - k_{p,y})$. The latter $\delta$-function provides the following relation between the angles $\vartheta_s^{(l)}$ and $\vartheta_i^{(l)}$ of modes $s$ and $i$ in the $l$th layer:

$$\vartheta_i^{(l)} = \arcsin \left( \frac{\omega_i}{\omega_s} \frac{\sin(\vartheta_i^{(l)}) - \omega_s \sin(\vartheta_s^{(l)})}{\omega_i} \right),$$

$$l = 0, \ldots, N + 1. \quad (19)$$

Solution of the Schrödinger equation to first order in incident vacuum state $|\psi_{s,TM,i}^{\text{out}}\rangle$ of signal field with $\beta$ polarization and idler field with $\gamma$ polarization in the form:

$$|\psi_{s,TM,i,\gamma}^{\text{out}}\rangle = |\text{vac}\rangle - \frac{i}{2 \sqrt{2 \pi c}} \sum_{l=1}^{N} \int_{0}^{\infty} d\omega_p \int_{0}^{\infty} d\omega_s \sqrt{\omega_s} \times \int_{0}^{\infty} d\omega_i \sqrt{\omega_i} \sum_{l=1}^{N} \sum_{m=0}^{L} \sum_{p=0}^{L} \sum_{s,TM,i,TM} \left( d^{(l)} e^{(l)} S^{11} \right) e^{(l)} a^{(l)} s,\beta,i,\gamma \right)|\text{vac}\rangle.

The wave-vectors $K^{(l)}$ introduced in Eq. (20) are defined as $K^{(l)}_{s,j,z} = k^{(l)}_{s,j,z}$ and $K^{(l)}_{j,u} = -k^{(l)}_{j,u}$ for $j = p, s, i$.

The operators $a_{m,F,\alpha}^{(l)}$ and $a_{m,B,\alpha}^{(l)}$ for $\alpha$ waves in mode $m$ in $l$th layer can be expressed in terms of the operators $a_{m,F,\alpha}^{(N+1)}$ and $a_{m,B,\alpha}^{(0)}$. These relations can be, e.g., written in the form:

$$\begin{align*}
(a_{m,F,\alpha}^{(l)}(\omega_m)) &= \frac{1}{\lambda_{p,m}} \sum_{j=1}^{p} [p(j)(\omega_m)T_{m,\alpha}^{(j-1)}(\omega_m)] \times \left( \begin{array}{ccc}
1/(S_{m,\alpha})_{11}(\omega_m) & (S_{m,\alpha})_{12}(\omega_m) / (S_{m,\alpha})_{11}(\omega_m) & 0 \\
-1 & 1 & 0
\end{array} \right) \times \left( \begin{array}{c}
\delta_{m,F,\alpha}^{(N+1)}(\omega_m) \\
\delta_{m,B,\alpha}^{(N+1)}(\omega_m)
\end{array} \right),
\end{align*}$$

$$m = s, i; \quad \alpha = TE, TM; \quad l = 1, \ldots, N. \quad (21)$$

The matrix $S_{m,\alpha}(\omega_m)$ used in Eq. (21) describes the propagation of $\alpha$ wave in field $m$ through the whole structure:

$$S_{m,\alpha}(\omega_m) = T_{m,\alpha}^{(N)}(\omega_m) \prod_{j=N}^{1} [p(j)(\omega_m)T_{m,\alpha}^{(j-1)}(\omega_m)],$$

$$m = s, i; \quad \alpha = TE, TM. \quad (22)$$

Similarly, the pump-field amplitudes $A_{p,F,\alpha}^{(l)}$ and $A_{p,B,\alpha}^{(l)}$ for $\alpha$ waves in $l$th layer can be determined from the amplitudes of the incident fields $A_{p,F,\alpha}^{(0)}$ and $A_{p,B,\alpha}^{(N+1)}$ as follows:

$$\begin{align*}
(A_{p,F,\alpha}^{(l)}(\omega_p)) &= \frac{1}{\lambda_{p,m}} \sum_{j=1}^{p} [p(j)(\omega_p)T_{p,\alpha}^{(j-1)}(\omega_p)] \times \left( \begin{array}{c}
\delta_{p,F,\alpha}^{(N+1)}(\omega_p) \\
\delta_{p,B,\alpha}^{(N+1)}(\omega_p)
\end{array} \right), \quad \alpha = TE, TM; \quad l = 1, \ldots, N. \quad (23)
\end{align*}$$

We note that the expression in Eq. (23) for the output state $|\psi_{s,TM,i,\gamma}^{\text{out}}\rangle$ including relations written in Eqs. (21) (24) can be formally recast into a compact form using the so-called left-to-right ($\Phi^{(+)}$) and right-to-left ($\Phi^{(-)}$) modes introduced in the classical electromagnetic theory of layered structures (for details, see (21)). Fields exiting the structure at $z = z_N$ are described by $\Phi^{(+)}(z)$ functions, whereas $\Phi^{(-)}(z)$ functions are appropriate for fields exiting at $z = z_0$. In classical theory, this corresponds to the picture in which every nonlinear layer is a source (emitting 'dipole') of photon pairs (30) and the fields leaving the structure are given as a sum of contributions from all layers.

We assume that the outgoing signal (idler) field is detected using an analyzer with the polarization that forms an angle $\varphi_s (\varphi_i)$ with respect to the TE-wave polarization direction (see Fig. 2). In order to get the right wavefunction, we transform the operators of the outgoing signal (idler) fields into the basis with the polarization vectors given by angles $\varphi_s (\varphi_i)$ and $\varphi_s + \pi/2 (\varphi_i + \pi/2)$ using the following formulas:

$$\begin{align*}
(a_{m,F,\alpha}^{(N+1)}(\omega_m)) &= \frac{1}{\lambda_{p,m}} \sum_{j=1}^{p} [p(j)(\omega_m)T_{m,\alpha}^{(j-1)}(\omega_m)] \times \left( \begin{array}{c}
\delta_{m,F,\alpha}^{(N+1)}(\omega_m) \\
\delta_{m,B,\alpha}^{(N+1)}(\omega_m)
\end{array} \right) \times \left( \begin{array}{c}
\cos(\varphi_m) \sin(\varphi_m) \\
-\sin(\varphi_m) \cos(\varphi_m)
\end{array} \right) \times \left( \begin{array}{c}
\delta_{m,F,\alpha}^{(N+1)}(\omega_m) \\
\delta_{m,B,\alpha}^{(N+1)}(\omega_m)
\end{array} \right),
\end{align*}$$

$$m = s, i; \quad \alpha = TE, TM. \quad (24)$$

Substituting relations in Eqs. (21), (23), and (24) into the expression $|\psi_{s,TM,i,TE}^{\text{out}}\rangle + |\psi_{s,TM,i,TE}^{\text{out}}\rangle + |\psi_{s,TM,i,TE}^{\text{out}}\rangle + |\psi_{s,TM,i,TE}^{\text{out}}\rangle$ determined using Eq. (20), we arrive at the
output state $|\psi_{s,\varphi_s,\varphi_i}\rangle$ describing a signal photon polarized along the angle $\varphi_s$, and an idler photon polarized along the angle $\varphi_i$:

$$|\psi_{s,\varphi_s,\varphi_i}\rangle = |\text{vac}\rangle + \int d\omega_s \int d\omega_i \left[ \phi^{FF}(\omega_s,\omega_i) \hat{a}_{s,F}^{(N+1)}(\omega_s) \hat{a}_{i,F}^{(N+1)}(\omega_i) |\text{vac}\rangle 
+ \phi^{FB}(\omega_s,\omega_i) \hat{a}_{s,F}^{(N+1)}(\omega_s) \hat{a}_{i,B}^{(1)}(\omega_i) |\text{vac}\rangle 
+ \phi^{BF}(\omega_s,\omega_i) \hat{a}_{s,B}^{(1)}(\omega_s) \hat{a}_{i,F}^{(N+1)}(\omega_i) |\text{vac}\rangle 
+ \phi^{BB}(\omega_s,\omega_i) \hat{a}_{s,B}^{(1)}(\omega_s) \hat{a}_{i,B}^{(1)}(\omega_i) |\text{vac}\rangle \right].$$ (26)

The function $\phi^{mn}(\omega_s,\omega_i)$ introduced in Eq. (26) has the meaning of probability amplitude of having a signal photon in field $m$ polarized along the angle $\varphi_s$ and its entangled idler twin in field $n$ polarized along the angle $\varphi_i$ at the output from the photonic-band-gap structure.

We are interested only in the part $|\psi_{s,i}^{(2)}\rangle$ of the output state $|\psi_{s,\varphi_s,\varphi_i}\rangle$ given in Eq. (26) that describes the generated photon-pairs. Including the time evolution of the free-fields outside the photonic-band-gap structure, we can write:

$$|\psi(t)_{s,i}\rangle^{(2)} = |\psi_{s,i}^{BF}(t)\rangle + |\psi_{s,i}^{FB}(t)\rangle + |\psi_{s,i}^{BB}(t)\rangle,$$ (27)

where

$$|\psi_{s,i}^{mn}(t)\rangle = \int_0^\infty d\omega_s \int_0^\infty d\omega_i \phi^{mn}(\omega_s,\omega_i) \times \hat{a}_s^\dagger(\omega_s) \hat{a}_i^\dagger(\omega_i) \exp(i\omega_s t) \exp(i\omega_i t) |\text{vac}\rangle,$$

$$m,n = F, B;$$ (28)

The creation operators $\hat{a}_m^\dagger$, $m = s_F, i_F, s_B, i_B$, introduced in Eq. (28) describe the linearly polarized photons outside the photonic-band-gap structure with polarization angles $\varphi_s$ and $\varphi_i$, and are given as:

$$\hat{a}_s^\dagger(\omega_s) = \hat{a}_{s,F}^{(N+1)}(\omega_s), \quad \hat{a}_i^\dagger(\omega_i) = \hat{a}_{i,F}^{(N+1)}(\omega_i),$$

$$\hat{a}_s^\dagger(\omega_s) = \hat{a}_{s,B}^{(1)}(\omega_s), \quad \hat{a}_i^\dagger(\omega_i) = \hat{a}_{i,B}^{(1)}(\omega_i).$$ (29)

We note that we do not explicitly express the dependence of quantities on the polarization angles $\varphi_s$ and $\varphi_i$ below.

C. Properties of the signal and idler fields outside the structure

The mean number $N_{s,i}^{mn}$ of photon pairs that have a signal photon in the frequency interval $\Delta\omega_s$ around frequency $\omega_s$, and its twin idler photon in frequency interval $\Delta\omega_i$ around frequency $\omega_i$ in field $mn$ is given by

$$N_{s,i}^{mn}(\omega_s,\omega_i) = \langle \psi_{s,i}^{mn}(t) | \hat{n}_{s,m}(\omega_s) \hat{n}_{i,m}(\omega_i) | \psi_{s,i}^{mn}(t) \rangle \Delta\omega_s \Delta\omega_i,$$ (30)

where the operator $\hat{n}_{j,m}(\omega_j)$, the density of photons, is defined as

$$\hat{n}_{j,m}(\omega_j) = \hat{a}_{j,m}^\dagger(\omega_j) \hat{a}_{j,m}(\omega_j), \quad j = s, i.$$ (31)

Using Eq. (28), the expression for $N_{s,i}^{mn}$ in Eq. (30) can be written as:

$$N_{s,i}^{mn}(\omega_s,\omega_i) = |\phi^{mn}(\omega_s,\omega_i)|^2 \Delta\omega_s \Delta\omega_i.$$ (32)

We get the following expressions for, e.g., the mean number $N_{s,i}^{mn}(\omega_s)$ of signal photons in frequency interval $\Delta\omega_s$ around frequency $\omega_s$:

$$N_{s,i}^{mn}(\omega_s) = \int_0^\infty d\omega_i |\phi^{mn}(\omega_s,\omega_i)|^2 \Delta\omega_i.$$ (33)

The overall number $N_{s,i}^{mn}$ of photon pairs emitted into field $mn$ is determined by the expression

$$N_{s,i}^{mn} = \int_0^\infty d\omega_s \int_0^\infty d\omega_i |\phi^{mn}(\omega_s,\omega_i)|^2.$$ (34)

The signal-field energy spectrum $S_{s}^{mn}(\omega_s)$ of field $mn$ can be easily determined using the expression

$$S_{s}^{mn}(\omega_s) = \hbar \omega_s N_{s,i}^{mn}(\omega_s) \Delta\omega_s,$$ (35)

The energy spectra $S_{s}^{mn}(\omega_J)$ ($j = s, i; m = F, B$) characterizing the outgoing down-converted fields without an inclusion of pair entanglement can be evaluated using the signal-field spectra $S_{s}^{mn}$ determined in Eq. (35); the idler-field spectra $S_{i}^{mn}$ are determined analogously:

$$S_{s}^{mn} = S_{s}^{FF} + S_{s}^{FB}, \quad S_{i}^{mn} = S_{i}^{FF} + S_{i}^{FB}, \quad S_{s}^{mn} = S_{s}^{BF} + S_{s}^{BB}, \quad S_{i}^{mn} = S_{i}^{BF} + S_{i}^{BB}.$$ (36)

The properties of the down-converted fields in the time domain can be conveniently described using a two-photon amplitude $A(\tau_s, \tau_i)$ giving the probability amplitude of detecting a signal photon at time $\tau_s$ and an idler photon at time $\tau_i$:

$$A^{mn}(\tau_s, \tau_i) = \langle \text{vac} | \hat{E}(\tau_s)(0, t_0 + \tau_s) \times \hat{E}(\tau_i)(0, t_0 + \tau_i + \tau_s) | \psi_{s,i}^{mn}(t_0) \rangle.$$ (37)

Assuming the state $|\psi_{s,i}^{mn}\rangle$ given in Eq. (26), the expression in Eq. (37) for the two-photon amplitude $A^{mn}$ can be rearranged into the form:

$$A^{mn}(\tau_s, \tau_i) = \frac{\hbar \omega_{0}^{mn}}{4\pi c E_B} \phi^{mn}(\tau_s, \tau_i),$$ (38)

where the ‘Fourier transform’ $\phi^{mn}(\tau_s, \tau_i)$ of the function $\phi^{mn}(\omega_s,\omega_i)$ has been introduced:

$$\phi^{mn}(\tau_s, \tau_i) = \frac{1}{2\pi} \int_0^\infty d\omega_s \int_0^\infty d\omega_i \sqrt{\frac{\omega_s \omega_i}{\omega_s \omega_i + \hbar \omega_{0}^{mn}} \phi^{mn}(\omega_s,\omega_i) \times \exp(-i\omega_s \tau_s) \exp(-i\omega_i \tau_i).$$ (39)
The photon flux of, e.g., the signal photons, \( N_s^{mn}(\tau_s) \) at time \( \tau_s \) over the transverse profile of area \( B \) in field \( mn \) is defined as

\[
N_s^{mn}(\tau_s) = \frac{\epsilon_0 c B}{2} \left| \psi_s^{mn}(t_0) \right|^2 \left( \phi_s^{(+)\star}(0, t_0 + \tau_s) \times \phi_s^{(+)}(0, t_0 + \tau_s) \right) \]

The photon flux \( N_s^{mn}(\tau_s) \) can be determined using the function \( \phi_s^{mn}(\omega_s, \omega_i) \):

\[
N_s^{mn}(\tau_s) = \frac{\hbar}{8\pi} \int_0^\infty d\omega_s \sqrt{\omega_s} \int_0^\infty d\omega_i \sqrt{\omega_i} \int_0^\infty d\omega_i \times \phi_s^{mn}(\omega_s, \omega_i) \phi_s^{mn}(\omega_s, \omega_i) \exp(i\omega_s \tau_s) \exp(-i\omega_i \tau_s).
\]

If the spectrum of the idler field is narrow, we may use the alternative expression

\[
N_s^{mn}(\tau_s) = \frac{\hbar \omega_i^0}{4} \int_{-\infty}^{\infty} dt \left| \phi_s^{mn}(\tau_s, \tau_i) \right|^2.
\]

Entanglement of the signal and idler photons in a pair can be detected in a Hong-Ou-Mandel interferometer (see Fig. 3). In order to achieve this type of interference between the signal and idler photons, we rotate polarizations of both photons such that they are the same, and subsequently introduce a relative time delay \( \tau_i \) between the two photons. Then two photons arrive at a 50/50% beam-splitter whose output ports are monitored by detectors. The measured coincidence-count rate \( R_c \) is given by the number of simultaneously detected photons at detectors \( D_A \) and \( D_B \), placed at the output ports of the beam-splitter in a given time interval. There occurs quantum interference between the two paths leading to a coincidence count; either a signal photon is detected by detector \( D_A \) and its twin idler photon by detector \( D_B \) or vice versa. The normalized coincidence-count rate \( R_n \) in this interferometer can be expressed as follows:

\[
R_n^{mn}(\tau_i) = 1 - \rho^{mn}(\tau_i),
\]

where

\[
\rho^{mn}(\tau_i) = \frac{1}{2R_0^{mn}} \int_{-\infty}^{\infty} dt_A \int_{-\infty}^{\infty} dt_B \operatorname{Re} \left[ A^{mn}(t_A, t_B - \tau_i) A^{mn\star}(t_B, t_A - \tau_i) \right]
\]

and

\[
R_0^{mn} = \frac{1}{2} \int_{-\infty}^{\infty} dt_A \int_{-\infty}^{\infty} dt_B |A^{mn}(t_A, t_B)|^2.
\]

The symbol \( \operatorname{Re} \) stands for real part, and the two-photon amplitude \( A^{mn} \) has been introduced in Eq. (31). Using the expressions in Eqs. (40) and (41), we arrive at:

\[
\rho^{mn}(\tau_i) = \frac{\hbar^2}{8c^2 B^2} \frac{1}{R_0^{mn}} \int_0^\infty d\omega_s \int_0^\infty d\omega_i \phi_s^{(+)\star}(\omega_s + \omega_i, \omega_s) \exp(i\omega_s \tau_i) \exp(-i\omega_i \tau_i)
\]

\[
R_0^{mn} = \frac{\hbar^2}{8c^2 B^2} \int_0^\infty d\omega_s \int_0^\infty d\omega_i \omega_s \omega_i |\phi_s^{mn}(\omega_s, \omega_i)|^2.
\]

D. Cw-limit

If cw pumping is considered, the spectrum is described using Eq. (40). As a consequence the following expressions are obtained:

\[
|\phi_s^{mn}(\omega_s, \omega_i)|^2 = f(\omega_s, \omega_i) \delta^2(\omega_p - \omega_s - \omega_i).
\]

In this case the second power of the Dirac delta function \( \delta \) is formal, so that the above expression should be replaced by:

\[
|\phi_s^{mn}(\omega_s, \omega_i)|^2 = \lim_{T \to \infty} \frac{2T}{2\pi} f(\omega_s, \omega_i) \delta(\omega_p - \omega_s - \omega_i),
\]

where the period of nonlinear interaction goes from \(-T\) to \(T\). Expressions for the physical quantities determined above have to be normalized by \(2T\), which indicates that these quantities are related to the period of \(1s\).

III. TYPICAL CHARACTERISTICS OF THE DOWN-CONVERTED FIELDS GENERATED FROM A PHOTONIC-BAND-GAP STRUCTURE

As an example, we study the properties of a nonlinear photon-band-gap structure composed of 25 nonlinear layers of GaN of thickness of 117 nm among which there are 24 linear layers of AIN with a thickness of 180 nm. Material characteristics of GaN and AIN can be found, e.g., in [31, 32]. This structure is resonant for the pump field at wavelength of 664.5 nm, designed to correspond...
to the first resonance peak near the band edge. This situation favors the efficient generation of photon pairs at roughly double the pump wavelength, at angles that correspond to the first, second, and third resonance peaks, respectively, for the down-converted fields. We assume that the GaN crystallographic x axis coincides with the z axis of propagation (see Fig. 1). In this configuration there is strong nonlinear interaction between TE components of the pump, signal, and idler beams. The nonlinear coefficient d for this geometry is chosen to be 10 pmV⁻¹.

A. Cw pumping

We first consider pumping by a cw laser tuned at first resonance peak, i.e. \( \lambda_p = 664.5 \) nm. A photon pair whose signal photon is emitted along the angle \( \theta_s \) may be described by a two-photon amplitude \( A \) with typical shapes both in time and spectral domains. In the spectral domain, the two-photon amplitude \( A(\omega_s, \omega_i) \) can be written in the form \( s(\omega_s)\delta(\omega_p - \omega_s - \omega_i) \), where the function \( s(\omega) \) is linearly proportional to the spectral amplitude of the signal field. This is a consequence of stationarity of the emitted down-converted fields. The probability \( |A(\tau_s, \tau_i)|^2 \) of detecting a signal photon at time \( \tau_s \) and an idler photon at time \( \tau_i \) is shown in Fig. 4a for mode FF (both photons exit the structure at \( z = z_N \)).

The shape of the probability \( |A(\tau_s, \tau_i)|^2 \) can be easily understood when we consider the fact that both photons in a pair are born together at the same instant of time, and then propagate independently inside the structure. This independent zig-zag propagation increases the average time delay between the two photons, which takes into account all possible realizations of the random process of propagation of a photon that undergoes multiple bounces inside the structure. The ‘random’ zig-zag propagation causes interference between different paths. This leads to a typical structure with local minima and maxima along the direction \( \tau_s + \tau_i = \) const; as shown in Fig. 4a. Also, the greater the difference \( \tau_s - \tau_i \) the smaller the value of the two-photon amplitude \( A \) because the propagation with more zig-zags is less probable. We note that typical stripes along the direction \( \tau_s - \tau_i = \) const reflect stationarity of the process.

Typical spectral properties of this structure are documented in Fig. 5 where the signal-field energy spectrum \( S_s^{FF} \) is depicted as a function of the angle \( \theta_s \) for field FF. The spectrum \( S_s^{FF} \) giving the probability of emission of a signal photon at frequency \( \omega_s \) along the angle \( \theta_s \) is a complex function in its variables because it is built up by interference of fields coming from the multilayer structure. A maximum photon-pair generation rate is obtained for \( \theta_s \approx 13.8 \) deg for degenerate frequencies (\( \omega_s \approx \omega_i \)). Photons from a generated photon pair can exit the structure also at \( z = z_0 \); their energy spectra \( S_i^{FF}(\omega_i, \theta_s) \), \( S_s^{BF}(\omega_s, \theta_s) \) and \( S_s^{BB}(\omega_s, \theta_s) \) are similar to that shown in Fig. 5. This is because efficient generation of photon pairs occurs provided both the signal and idler fields are resonant in the structure so that the generated photons exit the structure at \( z = z_0 \) or \( z = z_N \) with comparable probabilities. The signal-field intensity transmission \( |T_s|^2 \) as a function of normalized frequency \( 2\omega_s/\omega_p \) and angle \( \theta_s \) is shown in Fig. 4b for comparison.

The angle-dependence of the signal-field FWHM (full width at half maximum) \( \Delta \lambda_s \) of the energy spectrum in wavelengths and value of energy spectrum \( S_s^{max} \) at the central frequency \( \omega_s^c \) are shown in Fig. 4. High photon-pair generation rates are observed for the frequency-degenerate case (\( \omega_s^c \approx \omega_i^c \)) for values of the angle \( \theta_s \) approximately equal to 14, 35, and 55 degrees. For these values of the angle \( \theta_s \) the peaks of the signal-field intensity transmission \( |T_s|^2 \) cross the value \( \omega_s \) equal to \( \omega_p^c/2 \) (see Fig. 5). The first and highest peaks in the signal-field energy spectra \( S_s \) (see Fig. 7b) correspond to the case when both the signal and idler photons are tuned at the first resonance near the band edge. At this frequency, localization of the down-converted fields is maximum, and the nonlinear process is strongest. The other two sets of peaks in the signal-field energy spectra \( S_s \) correspond to the second and third peaks in the intensity transmission \( |T_s|^2 \). At these frequencies, the nonlinear interaction is somewhat weaker due to smaller
FIG. 5: Energy spectrum $S^{FF}_s$ of mode $FF$ versus normalized signal-field frequency $2\omega_s/\omega_p^0$ and angle $\theta_s$ of emission of a signal photon is shown in (a); cuts along the lines $\theta_s = 14$ deg (solid curve) and $\theta_s = 28$ deg (solid curve with *) are shown in (b); cw pumping is assumed; logarithmic scale is used on the $z$ axis.

FIG. 6: Signal-field intensity transmission $|T_s|^2$ as a function of normalized frequency $2\omega_s/\omega_p^0$ and angle $\theta_s$. Positions of peaks of resonance as they depend on the angle $\theta_s$ are clearly visible.

FIG. 7: FWHM $\Delta \lambda_s$ (a) and maximum value $S^\text{max}_s$ at the central frequency $\omega_c$ (b) for the signal-field energy spectrum $S_s(\omega_s)$ of modes $FF$ (*), $FB$ ($\Delta$), $BF$ (○), and $BB$ (●) as functions of the angle $\theta_s$ of emission of a signal photon are shown; cw pumping is assumed. For the other values of the angle $\theta_s$ constructive interference is less pronounced, the range of frequencies having constructive interference is broader, and spectral shapes with several peaks may occur (see Fig. 5b). We thus obtain down-converted fields with spectral FWHMs reaching even 80 nm (see Fig. 7a). In this case the FWHM indicates the entire active width, which might include several peaks. However, photon-pair generation rates are low in this case.

Quantum correlations (entanglement) between the signal and idler photons in a photon pair are visible in the profile of the normalized coincidence-count rate $R_n(\tau)$ in a Hong-Ou-Mandel interferometer (see Fig. 4 for mode $FF$). For values of the angle $\theta_s$ with strong constructive interference ($\theta_s \approx 14, 35, 55$ deg) this profile is given by a relatively broad dip (see Fig. 4). On the other hand, oscillating curves with several local minima and maxima characterize profiles of the normalized coincidence-count rates $R_n(\tau)$ for other values of the angle $\theta_s$. A typical profile for this case is shown in Fig. 4c. These profiles reflect broader spectra of the down-converted fields along these angles as well as a nonzero difference of the central frequencies $\omega_s^i$ and $\omega_s^c$ of the signal and idler fields. Period of these oscillations is proportional to $1/(\omega_s^c - \omega_s^i)$.

Position $\tau_c^i$ of the central dip, its FWHM $\Delta \tau_c$, and visibility $V$ of the normalized coincidence-count rate $R_n$ as functions of the angle $\theta_s$ are shown in Fig. 4. We can...
see in Fig. 9a that the maximum overlap of the signal and idler photon fields is reached for a nonzero mutual time delay \( \tau_l \) for nonsymmetric modes FB and BF. This means that the signal and idler photons exit the structure with a small mutual time delay. This nonzero mutual time delay means that interference effects inside the structure prefer the generation of photon pairs from nonlinear layers positioned closer to one edge of the structure, or in any case approximately co-located. The visibility \( V \) of the coincidence-count rate \( R_n \) is naturally observed for symmetric modes FF and BB. Values of the visibility \( V \) better than 0.9 can also be reached in nonsymmetric modes FB and BF provided that the fields are generated along the angles \( \theta_s \) in the vicinity of those with a strong constructive interference.

The structure of quantum correlations between the signal and idler fields in time domain is complex and prevents the visibility \( V \) from reaching higher values along the angles \( \theta_s \), where there are broad spectra of the down-converted fields. The width \( \Delta \tau_l \) of the dip in the normalized coincidence-count rate \( R_n(\tau) \) determines the entanglement time, i.e. the time interval in which both photons can be detected. The FWHM \( \Delta \tau_l \) of the central dip for the structure ranges from 50 fs for values of the angle \( \theta_s \), with broad spectra of the down-converted fields, to 150-250 fs for values of the angle \( \theta_s \) at which strong constructive interference occurs (see Fig. 9b).

**FIG. 8:** (a) Normalized coincidence-count rate \( R_{n,FF} \) of mode FF in Hong-Ou-Mandel interferometer as a function of relative time delay \( \tau_l \) and angle \( \theta_s \) of emission of a signal photon; (b) cuts along the lines \( \theta_s = 14 \text{ deg} \) (solid curve) and \( \theta_s = 28 \text{ deg} \) (solid curve with *); cw pumping is assumed.

**FIG. 9:** Position \( \tau_{cl}^c \) of the central dip (a), its visibility \( V \) \( \left[ V = \frac{p}{(1-p^2)} \right] \) (b), and FWHM \( \Delta \tau_l \) of the dip (c) for the normalized coincidence-count rate \( R_n(\tau) \) inHong-Ou-Mandel interferometer in modes FF (\( * \)), FB (\( \triangle \)), BF (\( \circ \)), and BB (\( \bullet \)) as functions of the angle \( \theta_s \) of emission of a signal photon; cw pumping is assumed.

**B. Pumping by an ultrashort pulse**

We now assume that the structure is pumped by an ultrashort pulse with an unchirped Gaussian profile [see Eq. (2)] having pulse duration \( \tau_p \) equal to 200 fs, and central (carrier) frequency \( \omega_0^p \) at the wavelength of 664.5 nm. The squared modulus \( |E_p|^2 \) of the incident pump-field amplitude spectrum \( E_{p,TE}(\omega_p) \) fits well into the peak of resonance of the pump-field intensity transmission \( |T_p(\omega_p)|^2 \), as depicted in Fig. 10.

Only signal and idler photons with frequencies \( \omega_s \) and \( \omega_i \) for which the sum \( \omega_s + \omega_i \) lies within the pump-pulse spectrum may be generated. The allowed values of the frequencies \( \omega_s \) and \( \omega_i \) are indicated in the graph...
The probability $|\phi^{FF}|^2$ of having a photon pair in mode $FF$ with a signal photon at the normalized frequency $2\omega_s/\omega_p^0$ and an idler photon at the normalized frequency $2\omega_i/\omega_p^0$ for pulsed pumping; the probability $|\phi^{FF}|^2$ is normalized such that one photon pair is emitted, i.e. $4 \int d\omega_s \int d\omega_i |\phi^{FF}(\omega_s, \omega_i)|^2(\omega_p^0)^2 = 1$; $\theta_s = 14$ deg.

The signal and idler fields are now emitted in the form of ultrashort, pulsed fields in multimode Fock states. A typical dependence of the signal-field photon flux $N_s^{FF}$ at time $\tau_s$ and angle $\theta_s$ is shown in Fig. 10. Fig. 11 suggests that the photon flux $N_s$ typically spreads to longer times as a consequence of zig-zag movement, i.e. multiple scattering, of photons inside the structure. Time delay $\tau_s^c$ and FWHM $\Delta \tau_s$ of the pulsed signal field as well as photon flux $N_{s\text{max}}^{max}$ at the center of the pulsed field as they depend on the angle $\theta_s$ are depicted in Fig. 12. The time delay $\tau_s^c$ of the signal pulse with respect to the pump pulse ranges from 70 fs to 200 fs. It reaches its maximum values for values of the angle $\theta_s$ with strong constructive interference ($\theta_s \approx 14, 35, 55$ deg). FWHM $\Delta \tau_s$ of the signal pulse goes from 270 fs to 320 fs. The narrower the spectrum of the signal field (given by $\Delta \lambda_s$ in wavelengths) the greater the signal-field pulse duration $\Delta \tau_s$ (compare Figs. 7 and 12b). The largest value of the photon flux $N_{s\text{max}}^{max}$ can be reached for the angle $\theta_s$ equal to 13.8 deg (see Fig. 12). These results clearly show that the considered photonic-band-gap structure maintains a pulsed char-
character of the nonlinear process and allows generation of
pulsed down-converted fields with an ultrashort duration. Such pulsed fields are required in many experi-
ments with photon pairs in which time synchronization
of several photon pairs is necessary.

C. Efficiency of the nonlinear process

The model that we have developed is one dimensional
with respect to the spatial coordinates, and does not in-
clude all aspects (especially those related to transverse
profiles of the interacting optical fields) of the nonlinear
process in a real structure. For this reason we do not
determine the absolute values of photon-pair generation
rates. Instead, we judge the efficiency of the suggested
structure which fully exploits the nonlinearity, but
does not rely on interference.

This reference structure has formally all linear indices
of refraction equal to one, so effects on the boundaries
between layers are suppressed. It is also assumed that
interacting optical fields) with respect to an ideal refer-
ence structure which fully exploits the nonlinearity, but

\[ \eta_{mn}(\omega_s) = \frac{S_{mn}^{\text{ref}}(\omega_s)}{S_{s}^{\text{ref}}(\omega_s)}, \]

where the signal-field energy spectrum \( S_{mn}^{\text{ref}} \) is given in
Eq. (50), and the signal-field energy spectrum \( S_{s}^{\text{ref}} \) of the
reference structure is determined in the same way using
the output state \( |\psi\rangle_{s,i}^{\text{ref}} \) written in Eq. (50).

The relative photon-pair generation rates \( \eta^{FF}, \eta^{FB}, \eta^{BF}, \) and \( \eta^{BB} \)
for the signal-field frequency \( \omega_s = \omega_p/2 \)
as a function of the angle \( \theta_s \) are shown in Fig. 15, assuming cw pumping. The relative photon-pair generation rates for pulsed pumping are lower in comparison with cw pumping, because frequencies at the edges of the pump-field spectrum have lower efficiencies than those in the middle. Despite this, the considered pulsed pumping has the overall relative photon-pair generation rate \( \eta \) equal to 9, whereas \( \eta = 12.5 \) for cw pumping for \( \theta_s \approx 13.8 \) deg. The structure that we consider is approximately 12 times more efficient than the reference structure, provided we consider all the emitted photon pairs (given by the overall relative photon-pair generation rate \( \eta \) in Fig. 15). Even when we restrict ourselves only to the mode \( FF \), we still have an enhancement of the nonlinear process by a factor of three. For comparison purposes, one layer of GaN of thickness 25 \( \times \) 117 nm (i.e., containing the same amount of nonlinear material as our structure) has the overall relative photon-pair generation rate \( \eta \) equal to 0.09 for values of the angle \( \theta_s \) less than 20 deg. The inclusion of linear layers of AlN inside the structure and the accompanying interference effects thus increase the photon-pair generation rates by two orders of magnitude.

**IV. CONCLUSION**

We have developed a quantum model of spontaneous parametric down-conversion (generating entangled photon pairs) in one-dimensional, nonlinear, layered media. Using the model we have determined a two-photon amplitude, and we have provided measurable characteristics of the down-converted fields: marginal signal and idler energy spectra, time-dependent photon fluxes of the signal and idler fields, coincidence-count interference patterns in the Hong-Ou-Mandel interferometer, and photon-pair generation rates.

A specific structure was suggested as an efficient source of photon pairs, and interference effects of the interacting fields can enhance the photon-pair generation rates by as much as two hundred times. The widths of the spectra of the down-converted fields and entanglement time of photons in a pair depend strongly on the angle of emission, and vary from 10 nm to 80 nm and from 50 fs to 250 fs, respectively. Pumping the structure with an ultrashort pulse of time duration of several hundreds of fs can lead to the generation of pulsed signal and idler fields extending over several hundreds of fs.

Therefore, we conclude that nonlinear one-dimensional photonic-band-gap structures represent a promising, new efficient source of photon pairs.
