COHOMOLOGICAL HALL ALGEBRAS AND CHARACTER VARIETIES

BEN DAVISON

ABSTRACT. In this paper we investigate the relationship between twisted and untwisted character varieties via a specific instance of the Cohomological Hall algebra for moduli of objects in 3-Calabi-Yau categories introduced by Kontsevich and Soibelman. In terms of Donaldson–Thomas theory, this relationship is completely understood via the calculations of Hausel and Villegas of the E polynomials of twisted character varieties and untwisted character stacks. We present a conjectural lift of this relationship to the cohomological Hall algebra setting.

1. Introduction

A fundamental object of research in the study of Higgs bundles on a genus $g$ complex curve is the twisted character variety

$\mathcal{M}^\text{Betti,tw}_{g,n} := \left\{ A_1, \ldots, A_g, B_1, \ldots, B_g \in \text{GL}_n(\mathbb{C}) \text{ such that } \prod_{i=1}^{g} A_i B_i A_i^{-1} B_i^{-1} = \exp(2\pi \sqrt{-1}/n) \text{Id}_{n \times n} \right\} / \text{PGL}_n(\mathbb{C}),$

where the set in brackets is considered as a sub algebraic variety of $\text{GL}_n(\mathbb{C})^{2g}$, and the action of $\text{PGL}_n(\mathbb{C})$ is the simultaneous conjugation action on all of the $A_i$ and the $B_i$. By the quotient we mean the categorical quotient in the category of complex schemes – this exists by a theorem of Nagata, see for instance [21]. By [13, Cor.2.2.7] the $\text{PGL}_n(\mathbb{C})$-action is free, so that the underlying topological space of (1) is the orbit space of the $\text{PGL}_n(\mathbb{C})$-action.

The link between (1) and Higgs bundles is as follows. Let $C$ be a nonsingular complete complex genus $g$ curve. The moduli space of semistable rank $n$ degree 1 Higgs bundles on $C$ is defined as follows:

$\mathcal{M}^\text{Dol}_{n,1}(C) := \left\{ \text{semistable } (V,\theta) \text{ with } V \text{ a vector bundle, } \theta \in H^0(\Omega_C \otimes \text{End}(V)), \deg(V) = 1 \text{ and } \text{rank}(V) = n \right\} / \text{isomorphism}.$

The $\theta$ in the above definition is known as the Higgs field, an isomorphism of pairs $(V,\theta) \rightarrow (V',\theta')$ is an isomorphism $f : V \rightarrow V'$ compatible with $\theta$ and $\theta'$ in the obvious way, and semistability is the condition that any sub-bundle $V'$ of $V$ preserved by the Higgs field satisfies

$$\deg(V')/\text{rank}(V') \leq 1/n.$$ 

The quotient (2) arises as a complex algebraic variety via Geometric Invariant Theory – see for example [25]. The nonabelian Hodge theorem, proved for complex curves via a combination of work of Hitchin [14], Corlette [2] and Donaldson [8], states that there is a diffeomorphism

$$\Phi : \mathcal{M}^\text{Betti,tw}_{g,n} \cong \mathcal{M}^\text{Dol}_{n,1}(C)$$

Throughout the paper we assume $g \geq 1$. 

1
and so we obtain an isomorphism
\[ H^\bullet(\Phi, \mathbb{Q}) : H^\bullet(\mathcal{M}_{g,1}^{\text{Betti}}(C), \mathbb{Q}) \cong H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \]
between the singular cohomology groups with rational coefficients of these two varieties (the reader may wish to consult the appendix of [26] for a very approachable overview of this part of the theory). The mixed Hodge structure on \( H^\bullet(\mathcal{M}_{g,1}^{\text{Betti}}(C), \mathbb{Q}) \) is pure of weight \( i \) (see for example the discussion in [31]); on the other hand the mixed Hodge structure on \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \) is not pure. This leads to some of the main problems in the subject: to understand the mixed Hodge structure \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \), and to describe the image of the weight filtration of \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \) on \( H^\bullet(\mathcal{M}_{g,1}^{\text{Betti}}(C), \mathbb{Q}) \) under the isomorphism \( H^\bullet(\Phi, \mathbb{Q}) \). The P=W conjecture of [6] states that the weight filtration on \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \) becomes the perverse filtration on \( H^\bullet(\mathcal{M}_{g,1}^{\text{Betti}}(C), \mathbb{Q}) \), defined in terms of the Hitchin system (see [6] for details). We will concentrate on \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \), saying a few words about the P=W conjecture at the end of the paper.

Consider instead the space
\[ \mathcal{M}_{g,n}^{\text{Betti},\text{tv}} := \left\{ \left. \prod_{i=1}^{g} A_iB_iA_i^{-1}B_i^{-1} = \text{Id}_{n \times n} \right\} / \text{GL}_n(\mathbb{C}) \right\}. \tag{3} \]
The space in brace brackets can be considered as a variety parametrising representations of \( \pi_1(C) \). If \( n \geq 2 \), then in contrast with the twisted character variety \( \mathcal{M}_{g,n}^{\text{tw}} \) the action of \( \text{GL}_n(\mathbb{C}) \) on the space in brackets is not free, even after replacing it with the action of \( \text{PGL}_n(\mathbb{C}) \) – for instance if \( 1 \) denotes the trivial representation of \( \pi_1(C) \), the stabiliser group of \( 1^{\otimes n} \) is the whole of \( \text{PGL}_n(\mathbb{C}) \). We consider \( \mathcal{M}_{g,n}^{\text{Betti},\text{tv}} \) as a stack theoretic quotient – it is isomorphic to the Artin stack of \( n \)-dimensional representations of \( \pi_1(C) \). An overview of Artin stacks, and in particular global quotient stacks, is provided by Gomez’s paper [12]. The definition of the stack \( \mathcal{M}_{g,n}^{\text{Betti},\text{tv}} \) as a functor from affine schemes to groupoids starts as follows: \( X = \text{Spec}(R) \) is sent to the groupoid of \( R \otimes \mathbb{C}[\pi_1(C)] \)-modules which are locally free of rank \( n \) over \( R \).

The space \( \mathcal{M}_{g,n}^{\text{Betti},\text{tv}} \) is smooth, and as such there is an isomorphism of mixed Hodge structures
\[ H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \cong H^\bullet_c(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \langle \text{dim}_C(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}) \rangle \]
given by Poincaré duality. Here and from now on we use the notation \( L\{i\} := L \otimes_{\mathbb{Q}} \mathbb{Q}(-i)[-2i] \), where \( \mathbb{Q}(-i) \) is the 1-dimensional mixed Hodge structure of weight \( 2i \) and the square brackets denote the cohomological shift of degree. On the other hand the untwisted character stack \( \mathcal{M}_{g,n}^{\text{Betti}} \) is not smooth, so it matters whether we study its cohomology or dual compactly supported cohomology. We pick the latter, and recall the definition in Section 2.

To relate \( H^\bullet(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \) to \( H^\bullet_c(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}, \mathbb{Q}) \langle \text{dim}_C(\mathcal{M}_{g,n}^{\text{Betti},\text{tv}}) \rangle \) we introduce some notation and results from [13]. Given a cohomologically graded mixed Hodge structure \( L^\bullet \), define the mixed Hodge polynomial
\[ \text{hp}(L^\bullet, x, y, t) = \sum_{a,b,j \in \mathbb{Z}} \dim_C \left( \text{Gr}_a^F(\text{Gr}_n^W(L^j \otimes_{\mathbb{Q}} \mathbb{C})) \right) x^a y^b t^j. \]
All mixed Hodge structures \( L \) that arise will satisfy \( \text{Gr}_a^F(\text{Gr}_n^W(L \otimes_{\mathbb{Q}} \mathbb{C})) = 0 \) if \( a \neq b \), so we may as well pass to the two variable specialization \( \text{hp}(L^\bullet, q, t) = \text{hp}(L^\bullet, \sqrt{q}, \sqrt{q}, t) \). Setting \( E(L^\bullet, q) := \text{hp}(L^\bullet, q, -1) \) we obtain a specialization of \( \text{hp}(H^\bullet_c(X, \mathbb{Q})) \), for \( X \) an algebraic variety, that is a
Here we give (6)

Consider the graded mixed Hodge structures fSym: Vectalgebra generated by with respect to the first Z Vect let Vect be the category of strict positively graded vector spaces, with finite dimensional graded pieces. Taking characteristic polynomials gives an isomorphism K0(Vect) → Z[[x±1, ..., x±1]]. Let Vect+ ⊂ Vect be the subcategory of vector spaces V which are strictly positively graded with respect to the first Z-grading, and for which the coefficient of each x±1 in χ([V]) is a formal function in the remaining variables with a finite order pole at the origin. We may identify K0(Vect+) with a subring of Z[[x±1, ..., x±1]] via χ. Furthermore there is a functor fSym: Vect+ → Vect taking V to the underlying vector space of the free commutative algebra generated by V, and a function

Exp := K0(fSym): K0(Vect+) → Z[[x±1, ..., x±1]].

Returning to character varieties, we relate the calculation of E(H•(Mg,nBetti, ∩ U), Q) to E(H•(Mg,nBetti, ∩ U), Q). Consider the graded mixed Hodge structures

\[ H^g_{\text{Betti}} := \bigoplus_{n \geq 0} H_c(M_{g,n}^{\text{Betti}}, Q)((1 - g)n^2)^*, \]

\[ H^g_{\text{Betti, tw}} = \bigoplus_{n \geq 1} H_c([M_{g,n}^{\text{Betti, tw}} / GL_1(\mathbb{C})], Q)((1 - g)n^2)^*. \]

Here we give \( M_{g,n}^{\text{Betti, tw}} \) the trivial GL(1, C) action. There is an isomorphism in cohomology

\[ H_c([M_{g,n}^{\text{Betti, tw}} / GL_1(\mathbb{C})], Q) \cong H_c \left( \left\{ A_1, ..., A_g, B_1, ..., B_g \in GL_n(\mathbb{C}) \text{ such that } \prod_{i=1}^g A_i B_i A_i^{-1} B_i^{-1} = \exp(2\pi \sqrt{-1}/n) \text{Id}_{n \times n} \right\} / GL_n(\mathbb{C}) \right), Q \]

so that (5) is the cohomology of the stack of twisted representations of the fundamental group of C. Applying E(•) to each graded piece of these mixed Hodge structures, we obtain formal power series E(\( H^g_{\text{Betti, tw}} \)) := \( \sum_{n \geq 1} E(H^g_{\text{Betti, tw}}) x^n \in xZ[[x, q^{±1}]] \) and E(\( H^g_{\text{Betti}} \)) ∈ Z[[x, q^{±1}]].

Combining the results of [13] gives the remarkable relation

\[ \text{Exp}(E(H^g_{\text{Betti, tw}})) = E(H^g_{\text{Betti}}). \]

The goal of this paper is to understand relation (7). We will show that, guided by the theory of BPS algebras, or cohomological Hall algebras of objects in 3-Calabi-Yau categories, we can put a kind of Hopf algebra structure on the mixed Hodge structure \( H^g_{\text{Betti}} \), and we conjecture that the resulting algebra satisfies a PBW theorem. The relation (7) then becomes the statement that the E series of the subspace of primitive elements in the PBW basis for \( H^g_{\text{Betti}} \) is exactly the E series of \( H^g_{\text{Betti, tw}} \), leading naturally to our main conjecture.

\textbf{Conjecture 1.1.} \textit{There is an isomorphism of mixed Hodge structures}

\[ f\text{Sym}(H^g_{\text{Betti, tw}}) \cong H^g_{\text{Betti}}. \]
The conjecture implies that the mixed Hodge polynomials of the spaces $M_{g,n}^{\text{Betti, tu}}$ are encoded in the mixed Hodge power series of the spaces $M_{g,n}^{\text{Betti}}$, and vice versa, providing new lines of attack on the conjectures of Hausel and Rodriguez-Villegas regarding these polynomials.

2. Equivariant Cohomology and Vanishing Cycles

Before launching into the construction of cohomological Hall algebras arising from Jacobi algebras and vanishing cycles, we collect together some of the background definitions.

Let $X$ be an arbitrary variety equipped with a $G$-action, and a faithful embedding of algebraic groups $G \subset \text{GL}_C(m)$. We first define the compactly supported cohomology of the global quotient stack $[X/G]$ (see [12] for a definition of this stack). For $M \geq m$ let $\text{Fr}(m, M)$ be the space of $m$-tuples of linearly independent vectors in $\mathbb{C}^M$. There are natural inclusions $\text{Fr}(m, M) \to \text{Fr}(m, M + 1)$ inducing inclusions

$$X \times_G \text{Fr}(m, M) \xrightarrow{i_M} X \times_G \text{Fr}(m, M + 1)$$

and Gysin morphisms in the category of mixed Hodge structures

$$H_c(X \times_G \text{Fr}(m, M), \mathbb{Q})\{-mM\} \to H_c(X \times_G \text{Fr}(m, M + 1), \mathbb{Q})\{-m(M + 1)\}$$

obtained by applying $(X \times_G \text{Fr}(m, M + 1) \to \text{pt})_!$ to the adjunction map

$$i_M!\mathbb{Q}_{X \times_G \text{Fr}(m, M)}\{-mM\} \to \mathbb{Q}_{X \times_G \text{Fr}(m, M + 1)}\{-m(M + 1)\}.$$

We define $H_c([X/G], \mathbb{Q})$ to be the limit of these maps.

Now let $X$ be a smooth complex variety, and let $f \in \Gamma(\mathcal{O}_X)$ be a function on it. Let $D^b_c(X, \mathbb{Q})$ denote the derived category of sheaves of $\mathbb{Q}$-vector spaces on $X$ with analytically constructible cohomology (all subsequent functors are assumed to be derived). Then if we define $X_{>0} := \{x \in X|f(x) \in \mathbb{R}_{>0}\}$ and $X_0 := \{x \in X|f(x) = 0\}$, we define the functor $\psi_f: D^b_c(X, \mathbb{Q}) \to D^b_c(X, \mathbb{Q})$ by

$$\psi_f = (X_0 \to X)_*(X_0 \to X)^* (X_{>0} \to X)_*(X_{>0} \to X)^*.$$

For instance, applying $\psi_f$ to $\mathcal{O}_X$, we obtain the sheaf

$$(X_0 \to X)_*(X_0 \to X)^* (X_{>0} \to X)_* \mathcal{O}_{X_{>0}}$$

supported on $X_0$, the sheaf of nearby cycles on $X$. As defined this is actually an object in $D^b_c(X, \mathbb{Q})$, and is rarely represented by an actual sheaf. Via the adjunction $\text{id} \to (X_{>0} \to X)_*(X_{>0} \to X)^*$ we obtain a natural transformation

$$(X_0 \to X)^* (X_0 \to X)^* \xrightarrow{\varphi} \psi_f$$

and we define $\varphi_f := \text{cone}(\varphi)$ (with some care this cone can be made functorial – see for instance Ex. VIII.13 of [15]). By abuse of notation we will often just denote $\varphi_f := \varphi_f \mathcal{O}_X[-1]$. The shift here is for book-keeping purposes later. In fact the functor $\varphi_f$ defined above lifts to an endofunctor of the derived category of mixed Hodge modules $\varphi_f: D^b(M\text{HM}(X)) \to D^b(M\text{HM}(X))$. For this paper we needn’t say anything about the category of mixed Hodge modules except that there is a forgetful functor $D^b(M\text{HM}(X)) \to D^b_c(X, \mathbb{Q})$ which is faithful, the six functor formalism of Grothendieck and the functors $\psi_f$ and $\varphi_f$ lift to $D^b(M\text{HM}(X))$, and $D^b(M\text{HM}(\text{pt}))$ is the derived category of mixed Hodge structures. The interested reader can consult [22] for
more details. We recover Deligne’s mixed Hodge structure on $\mathbb{H}^\bullet(X, \mathbb{Q})$ for $X$ an arbitrary variety, by applying $(X \to pt)_*$ to the constant mixed Hodge module $\mathbb{Q}(0)$ on $X$, and the mixed Hodge structure of Steenbrink and Navarro Aznar on $\mathbb{H}^\bullet(X, \wp_f)$ by applying $(X \to pt)_*$ to $\wp_f \in D^b(\mathbb{MHM}(X))$. We will use four facts regarding vanishing cycles:

1. For $p: X \to Y$ a proper map and $f \in \mathfrak{G}(O_Y)$, there is a natural isomorphism $\wp_f p_* \to p_* \wp_{f_p}$.
2. For $q: X \to Y$ an $n$-dimensional affine fibration, there is a natural isomorphism $\mathbb{H}^\bullet(Y, \wp_f) \cong \mathbb{H}^\bullet(X, \wp_f)^{-\{n\}}$.
3. The support of $\wp_f \mathbb{Q}_X$ is exactly the degeneracy locus of $f$. By shrinking $X$ we always assume that this is a subspace of $f^{-1}(0)$.
4. (Thom–Sebastiani isomorphism) For $f_i \in \mathfrak{G}(O_Y)$ two functions, there is a natural isomorphism $\mathbb{H}_c(Y_1, \wp_{f_1}) \otimes \mathbb{H}_c(Y_2, \wp_{f_2}) \cong \mathbb{H}_c(Y_1 \times Y_2, \wp_{\pi_1^* f_1 + \pi_2^* f_2})$.

The fourth fact is a theorem of Massey [18], at the level of the underlying cohomologically graded vector spaces, and an unpublished theorem of Saito at the level of ‘monodromic mixed Hodge structures’. For the mixed Hodge structures we will encounter, there is an independent proof from the theory of dimensional reduction, see the appendix of [4].

Finally, let $X$ be a smooth algebraic variety equipped with a $G$-action, where as above we have a faithful embedding $G \subset \text{GL}_\mathbb{C}(m)$, and let $f$ be a $G$-invariant function on $X$. Then $f$ induces functions $f_M$ on each of the spaces $X \times_G \text{Fr}(m, M)$, and applying $(X \times_G \text{Fr}(m, M + 1) \to pt)_! \wp_{f_{M+1}}$ to the adjunction map (10), and applying the natural isomorphism of fact (11) above, we obtain Gysin maps

$$(11) \quad \mathbb{H}_c(X \times_G \text{Fr}(m, M), \wp_{f_M}) \{ -mM \} \to \mathbb{H}_c(X \times_G \text{Fr}(m, M + 1), \wp_{f_{M+1}}) \{ -m(M + 1) \}$$

and we define $\mathbb{H}_c([X/G], \wp_f)$ to be the limit of these maps.

### 3. The Theory of BPS State Counting for 3–Calabi–Yau Categories

The algebra structure that we define on $\mathcal{R}_g^{\text{Betti}}$ comes from the Hall algebra construction in noncommutative 3-Calabi-Yau geometry introduced by Kontsevich and Soibelman in [17]. We provide a short overview of the theory, in the generality that we need.

**Definition 3.1.** [16] A (not necessarily commutative) algebra $B$ is nc smooth if it is finitely generated and for any algebra $A$, and any two-sided ideal $I \triangleleft A$ satisfying $I^n = 0$ for $n \gg 0$, every algebra homomorphism $\tilde{f}: B \to A/I$ lifts to a morphism $\tilde{f}: B \to A$ such that the composition $B \to A \to A/I$ is equal to $\tilde{f}$.

Given a finitely generated algebra $B$ we define $\text{Rep}_n(B)$ to be the stack of $n$-dimensional representations of $B$. In the language of sheaves of groupoids, if $A$ is a commutative algebra, $\text{Rep}_n(B)(\text{Spec}(A))$ is the groupoid obtained by forgetting noninvertible morphisms in the category of $A \otimes B$-modules, locally free over $A$, of rank $n$ at each geometric point of $A$.

**Convention 3.2.** It will often be convenient to fix a presentation for $B$:

$$B \cong \mathbb{C}(x_1, \ldots, x_t)/(r_1, r_2, \ldots).$$
Let \( \text{Rep}_n(B) \subset \text{Mat}_{n \times n}(\mathbb{C})^{\times t} \) be the subscheme cut out by the matrix valued relations \( r_1, r_2, \ldots \).

Then \( \text{Rep}_n(B) \) is isomorphic to the stack theoretic quotient \( \text{Rep}_n(B)/\text{GL}_n(\mathbb{C}) \) formed by equipping \( \text{Mat}_{n \times n}(\mathbb{C})^{\times t} \) with the simultaneous conjugation action. From this description we see that \( \text{Rep}_n(B) \) is a finite type global quotient Artin stack. If \( f \) is a function on \( \text{Rep}_n(B) \) we denote by \( \overline{f} \) the induced function on \( \text{Re}p_n(B) \).

**Proposition 3.3.** Let \( B \) be a nc smooth algebra. Then \( \text{Rep}_n(B) \) is a finite type smooth Artin stack.

**Proof.** We have already seen that \( \text{Rep}_n(B) \) is a finite type Artin stack. It is enough to show that the atlas \( \text{Rep}_n(B) \) is smooth (see [12]). Recall the following criterion for smoothness [7]; a finite type scheme \( Y \) is smooth if every map \( \text{Spec}(R/I) \to Y \), for \( I \) a nilpotent ideal of \( R \) an Artinian local ring, can be lifted to a map \( \text{Spec}(R) \to Y \). A map \( \text{Spec}(R/I) \to \text{Re}p_n(B) \) is given by a map \( B \to \text{Mat}_{n \times n}(R/I) \cong \text{Mat}_{n \times n}(R)/\text{Mat}_{n \times n}(I) \). Now a lift exists since \( \text{Mat}_{n \times n}(I) \) is a 2-sided nilpotent ideal of \( \text{Mat}_{n \times n}(R) \). \( \square \)

**Example 3.4.** Let \( Q \) be a quiver with vertices \( Q_0 \) and arrows \( Q_1 \) (our quivers are always assumed to satisfy \( |Q_0|, |Q_1| < \infty \)). Let \( B = CQ \) be the free path algebra of \( Q \). Then \( B \) is a nc smooth algebra, and

\[
\text{Rep}_n(B) \cong \sum_{n_1, \ldots, n_{|Q_0|} \geq 0} \frac{\prod_{a \in Q_1} \text{Hom}(\mathbb{C}^{n_a}, \mathbb{C}^{n_t(a)})}{\prod_{i \in Q_0} \text{GL}_{n_i}(\mathbb{C})},
\]

is a finite type smooth stack (here the \( \prod_{i \in Q_0} \text{GL}_{n_i}(\mathbb{C}) \)-action is via change of basis on the \( \mathbb{C}^{n_i} \)).

**Remark 3.5.** As we see from Example 3.4, the stack of \( n \)-dimensional representations of a quiver \( Q \), and hence the stack of representations of \( CQ/I \) for any two-sided ideal \( I \), breaks naturally into a disjoint union indexed by \( \gamma \in \mathbb{N}^{Q_0} \) with \( \sum \gamma_i = n \). We define \( \text{Rep}_\gamma(CQ/I) \) to be the substack corresponding to the dimension vector \( \gamma \).

**Example 3.6.** Let \( Q \) be a quiver, and let \( Q' \subset Q \) be a subquiver. For each arrow \( a \in Q_1' \) add an arrow \( a^* \) with \( s(a^*) = t(a) \) and \( t(a^*) = s(a) \) to form a new quiver \( \overline{Q} \) (here and elsewhere \( s \) and \( t \) stand for source and target). Recall that in the path algebra \( CQ \), the symbol \( e_i \) denotes the path of zero length at the vertex \( i \). Then we define

\[
\overline{CQ} := \langle a^*a = e_i, aa^* = e_t(a) | a \in Q_1' \rangle,
\]

the localized path algebra. Using the previous example one can see that this algebra is smooth, and

\[
\text{Rep}_\gamma(\overline{CQ}) \cong \left( \prod_{a \in Q_1 \setminus Q'_1} \text{Hom}(\mathbb{C}^{\gamma_s(a)}, \mathbb{C}^{\gamma_t(a)}) \times \prod_{a \in Q'_1} \text{Iso}(\mathbb{C}^{\gamma_s(a)}, \mathbb{C}^{\gamma_t(a)}) \right) / \prod_{i \in Q_0} \text{GL}_{\gamma_i}(\mathbb{C}),
\]

is a Zariski open substack of \( \text{Rep}_n(CQ) \). We use the notation \( \text{Iso}(V', V'') \) to denote isomorphisms from a vector space \( V' \) to a vector space \( V'' \). The stack \( \text{Rep}_\gamma(CQ) \) is a dense open substack of \( \text{Rep}_\gamma(CQ) \) if and only if for every \( a \in Q', \gamma_s(a) = \gamma_t(a) \).
Given $W$ (called a potential) in the vector space quotient $B/[B,B]$ we obtain a function $\text{tr}(W)_\gamma$ on $\text{Rep}_\gamma(B)$ as follows. First, lift $W$ to an element $\tilde{W} \in B$. For a representation $\rho$ of $B$, we obtain an element $\text{tr}(\rho(\tilde{W}))$, independent of which lift $\tilde{W}$ we choose, by cyclic invariance of the trace. It follows that $\rho \to \text{tr}(\rho(\tilde{W}))$ defines a function on $\text{Rep}_\gamma(B)$.

Given the pair $(B,W)$ of a smooth noncommutative algebra with potential, one forms as in [11] the Jacobi algebra $\text{Jac}(B,W)$. We will restrict to the case in which $B = \mathbb{C}Q$ is the localized path algebra associated to a pair $Q' \subset Q$, and $W \in \text{Image}(\mathbb{C}Q/[\mathbb{C}Q,\mathbb{C}Q] \to B/[B,B])$ is a linear combination of cyclic paths in $Q$ – this simplifies the definition of $\text{Jac}(B,W)$. Given an arrow $a \in Q_1$, and a cyclic path in $Q$, we define

$$
\frac{\partial u}{\partial a} = \sum_{v,w \text{ paths in } Q} wv
$$

and we extend to a function $\partial/\partial a : \mathbb{C}Q/[\mathbb{C}Q,\mathbb{C}Q] \to B$ by linearity. Then

$$
\text{Jac}(B,W) := B/\langle \partial W/\partial a | a \in Q_1 \rangle.
$$

**Example 3.7.** Let $Q$ be the quiver with one vertex and three loops, labelled $x, y, z$, and let $Q' = Q$. Then the localized path algebra $\mathbb{C}Q$ is $\mathbb{C}\langle x^{\pm 1}, y^{\pm 1}, z^{\pm 1} \rangle$, the Laurent polynomial algebra in three noncommuting variables. Let $W = x[y, z]$. Then

$$
\begin{align*}
\partial W/\partial x &= [y, z] \\
\partial W/\partial y &= [z, x] \\
\partial W/\partial z &= [x, y]
\end{align*}
$$

and $\text{Jac}(\mathbb{C}Q, W) \cong \mathbb{C}[x^{\pm 1}, y^{\pm 1}, z^{\pm 1}]$, the commutative Laurent polynomial algebra in three variables. Note that $\text{Jac}(\mathbb{C}Q, W) \cong \mathbb{C}[\pi_1((S^1)^3)]$, the fundamental group algebra of the 3-torus. We will see with Proposition 4.2 that some other fundamental group algebras of 3-manifolds arise as Jacobi algebras.

We consider $\text{Rep}_\gamma(\text{Jac}(B,W))$ as a substack of $\text{Rep}_\gamma(B)$ in the natural way: the relations $\partial W/\partial a$ define matrix valued functions on $\text{Rep}_\gamma(B)$, and $\text{Rep}_\gamma(\text{Jac}(B,W))$ is the stack theoretic degeneracy locus of $\text{tr}(W)_\gamma$.

**Proposition 3.8.** [11 Sec.2.3] [24 Prop.3.8]: $\text{Rep}_\gamma(\text{Jac}(B,W)) \subset \text{Rep}_\gamma(B)$ is the stack-theoretic degeneracy locus of $\text{tr}(W)_\gamma$.

From now on we assume that $B$ is the (possibly localized) path algebra of a quiver $Q$. For $W \in \mathbb{C}Q/[\mathbb{C}Q,\mathbb{C}Q]$, by fact [3] from Section 2 and Proposition 3.8 $\varphi_{\text{tr}(W)_\gamma}$ may be considered as an object of $D^b_c(\text{Rep}_\gamma(B,W),\mathbb{C})$, although we have defined it as an object of $D^b_c(\text{Rep}_\gamma(B),\mathbb{C})$. We define the mixed Hodge structure

$$
\mathcal{H}_{B,W,\gamma} := H^\bullet_c(\text{Rep}_\gamma(\text{Jac}(B,W)), \varphi_{\text{tr}(W)_\gamma}) \{ -\dim_{\mathbb{C}}(\text{Rep}_\gamma(B))/2 \}^* \\
= H^\bullet_c(\text{Rep}_\gamma(B), \varphi_{\text{tr}(W)_\gamma}) \{ -\dim_{\mathbb{C}}(\text{Rep}_\gamma(B))/2 \}^*
$$

\[\text{In the sequel } -\dim_{\mathbb{C}}(\text{Rep}_\gamma(B))/2 \text{ will always be an integer. See [17 Sec.3.4] for the general case.}\]
and

$$\mathcal{H}_{B,W} := \bigoplus_{\gamma \in \mathbb{N}Q_0} \mathcal{H}_{B,W,\gamma}.$$  

Next we recall the algebra structure on $\mathcal{H}_{B,W}$. For $\gamma' + \gamma'' = \gamma$ we define $\text{Rep}_{\gamma',\gamma''}(B)$ to be the stack of pairs $\rho_1 \subset \rho_2$, where $\rho_1$ is a $\gamma'$-dimensional representation of $B$ and $\rho_2$ is a $\gamma$-dimensional representation. We may describe this stack as in Example 3.6:

$$\text{Rep}_{\gamma',\gamma''}(B) \cong \left[ \prod_{a \in Q_1 \setminus Q'_1} \text{Hom}^p(C^{\gamma_{a}(a)}, C^{\gamma_{t}(a)}) \times \prod_{a \in Q'_1} \text{Iso}^p(C^{\gamma_{a}(a)}, C^{\gamma_{t}(a)}) \right] / \prod_{i \in Q_0} P_{\gamma'_i,\gamma''_i}(\mathbb{C}),$$

where $P_{\gamma'_i,\gamma''_i}(\mathbb{C}) \subset \text{GL}_{\gamma_i}(\mathbb{C})$ is the subgroup preserving $C^{\gamma_i}$, and $\text{Hom}^p$ and $\text{Iso}^p$ are the subspaces of Hom and Iso preserving the flags $C^{\gamma_i} \subset C^{\chi_i}$. There is a diagram

$$\text{Rep}_{\gamma'}(B) \times \text{Rep}_{\gamma''}(B) \xrightarrow{q} \text{Rep}_{\gamma',\gamma''}(B) \xrightarrow{i} \text{Rep}_{\gamma}(B)$$

and the idea of the multiplication on $\mathcal{H}_{B,W}$ is to pull back compactly supported cohomology along the map $i$, then push forward along the map $q$, then dualize. In a little more detail, we have seen that $\text{Rep}_{\gamma',\gamma''}(B)$ is the stack theoretic quotient of an affine scheme $X$ by $P = \prod_{i \in Q_0} P_{\gamma'_i,\gamma''_i}$, while $\text{Rep}_{\gamma}(B)$ is the stack theoretic quotient of an affine scheme $Y$ by $G = \prod_{i \in Q_0} \text{GL}_{\gamma_i}(\mathbb{C})$. The compactly supported cohomology $H_c([X/P], \varphi_{W,W})$ is approximated (as in [11]) by $H_c(X \times P \text{Fr}(n,N), \varphi_{W,W})$, where $n = \sum \gamma_i$, and $H_c(Y/G, \varphi_{W,W})$ is defined similarly. The inclusion $X \to Y$ is $P$-equivariant, and we have a proper composition of maps

$$X \times P \text{Fr}(n,N) \xrightarrow{i_1} Y \times P \text{Fr}(n,N) \xrightarrow{i_2} Y \times G \text{Fr}(n,N).$$

Applying the functor $\varphi_{W,W} \text{Fr}(n,N)$ to the adjunction $\mathbb{Q}_{Y \times G \text{Fr}(n,N)} \to i_2^* i_1^* \mathbb{Q}_{X \times P \text{Fr}(n,N)}$ and using fact (1) regarding vanishing cycles we obtain a map

$$H_c(X \times G \text{Fr}(n,N), \varphi_{W,W}) \to H_c(X \times P \text{Fr}(n,N), \varphi_{W,W})$$

which gives the desired map $H_c(Y/G, \varphi_{W,W}) \to H_c(X/P, \varphi_{W,W})$ in the limit. The push-forward along $q$ is defined in much the same way, this time expressing the map $q$ in terms of affine fibrations, and using fact [2] regarding vanishing cycles.

Via the above constructions and the Thom–Sebastiani isomorphism one obtains an associative product $m$: $\mathcal{H}_{B,W} \otimes \mathcal{H}_{B,W} \to \mathcal{H}_{B,W}$ (see [17] for more details). This is the cohomological Hall algebra (CoHA) associated to $(B,W)$.

**Remark 3.9.** One may consider the subalgebra that is the sum of those $\mathcal{H}_{B,W,\gamma}$ for which $\gamma$ satisfies the condition that if $\gamma_i \neq \gamma_j$, there are as many arrows in $Q$ from $i$ to $j$ as from $j$ to $i$. For this subalgebra the multiplication $m$ preserves the cohomological grading, and is a morphism of mixed Hodge structures.

**Remark 3.10.** Again imposing the restriction of Remark 3.9 the CoHA $\mathcal{H}_{B,W}$ carries a richer structure, making it into a kind of Hopf algebra object in the derived category of mixed Hodge structures. For a $G$-variety $X$ there is a natural morphism $[X/G] \to [X/G] \times [pt/G]$, inducing the structure of a $\Pi^\bullet([pt/G], \mathbb{Q}) \cong H^\bullet_G(pt, \mathbb{Q})$-module on $H^\bullet([X/G], \varphi_f)^*$, for $f$ a $G$-invariant
function on $X$. There is a localized coproduct $\mathcal{H}_{B,W,\gamma} \to (\mathcal{H}_{B,W,\gamma'} \otimes \mathcal{H}_{B,W,\gamma''}) \otimes A_{\text{ev},\gamma''}$, where $A_{\text{ev},\gamma''} := \mathcal{H}_G^{\bullet}(\text{pt}, \mathbb{Q}) \otimes \mathcal{H}_G^{\bullet}(\text{pt}, \mathbb{Q})$, and $A_{\text{ev},\gamma''}$ is the localization of $A_{\text{ev},\gamma''}$ at the equivariant Euler class of a specific virtual bundle on $\text{Rep}_{\gamma'}(B) \times \text{Rep}_{\gamma''}(B)$. This makes $\mathcal{H}_{B,W}$ into a localized Hopf algebra (see [4]).

4. The link between Character Varieties and BPS State Counting

The link between the cohomology of character varieties and BPS state counting, or CoHAs, comes in two steps. Firstly we describe a class of Jacobi algebras $\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)$ that arise as noncommutative compactifications of $\mathbb{C}[\pi_1(\Sigma_g \times S^1)]$. Then we use \textit{dimensional reduction}, which gives an isomorphism of mixed Hodge structures $\mathcal{H}_{\mathbb{C}Q_\Delta, W_\Delta,(n,...,n)} \cong \mathcal{H}^{\text{Betti}}_{g,n}$.

The first step requires the theory of brane tilings of Riemann surfaces. A brane tiling $\Delta$ of $\Sigma_g$ is an embedding of a bipartite graph $\Gamma$ in $\Sigma_g$ such that each connected component of $\Sigma_g \setminus \Gamma$ (or ‘tile’) is simply connected. We assume that we are given a colouring of the vertices of $\Gamma$ with black and white such that no two vertices of the same colour are joined by an edge. We pick an isomorphism of mixed Hodge structures $\mathcal{H}_{\mathbb{C}Q_\Delta, W_\Delta,(n,...,n)} \cong \mathcal{H}^{\text{Betti}}_{g,n}$.

First pick $v \in V(\Delta)$, dual to the arrow $a \in (Q_\Delta)_i$. The expression $\partial W/\partial a$ is the difference $c'_v - c''_v$, where $c'_v$ and $c''_v$ are obtained by cyclically permuting $c_v$ so that $a$ is at the front, and then deleting it. In other words, the relation $\partial W/\partial a = 0$ imposes the condition that two homotopic paths in the quiver $Q_\Delta$ become equal in the Jacobi algebra $\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)$. See Fig. [4] for an illustration. This does not however give a bijection between isoclasses of paths from $i$ to $j$ in $Q_\Delta$ under the equivalence relation given by equality in $\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)$ and homotopy classes of paths between the vertices $i$ and $j$ in $\Sigma_g$; for instance the path $c_u$ is contractible, but is not equal to the path $c_{s(u)}$ in $\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)$.

We obtain a better picture by thinking of paths in $Q = Q_\Delta$ as moving in three dimensions. For this, assume that the edges of $Q$ are graded by the numbers $\mathbb{Q}$ in such a way that $W_\Delta$ is homogeneous of weight 1 – we then say that $\Delta$ is a graded brane tiling. Since $Q$ is already embedded in $\Sigma_g$, we may define an embedding $\iota: Q_0 \to \Sigma_g \times S^1$ by defining a function $\pi_{S^1} \iota: Q_0 \to \mathbb{R}/\mathbb{Z}$. First pick $v_0 \in Q_0$ and define $\pi_{S^1} \iota(v_0) = [0]$. For arbitrary $v \in Q_0$ define $\pi_{S^1} \iota(v) = [|p|]$ in terms of our $\mathbb{Q}$-grading, where $p$ is any path in $Q$ from $v_0$ to $v$. This $\pi_{S^1} \iota$ is well-defined by [3, Lem.2.8]. We extend the embedding $\iota: Q_0 \subset \Sigma_g \times S^1$ to a smooth embedding $Q \subset \Sigma_g \times S^1$ which becomes the existing embedding $Q \subset \Sigma_g$ after projection onto $\Sigma_g$. We assume that the embedding is minimal in the following sense: considering each arrow $a$ as a path $\alpha: [0,1] \to \mathbb{R}/\mathbb{Z}$ via the projection onto $S^1$, the derivative of $\alpha$ is nonnegative, and $\int_0^1 \alpha' = |a|$.
We say that $\Delta$ is consistent if for all paths $u_1, u_2$ from $i$ to $j$ in $Q$, if $c_v u_1 = c_v u_2$, considered as elements of $\text{Jac}(CQ_\Delta, W_\Delta)$, then $u_1 = u_2$ in $\text{Jac}(CQ_\Delta, W_\Delta)$. Here $c_v$ is a minimal cycle around a vertex in $\Delta$ with $s(c_v) = j$. If we consider $\text{Jac}(CQ_\Delta, W_\Delta)$ in the natural way as an algebra with many objects (the objects being $Q_0$), consistency is equivalent to the condition that $\text{Jac}(CQ_\Delta, W_\Delta)$ is an integral domain with many objects. This condition is easy to satisfy, in particular, for every genus $g$ there is a consistent, graded brane tiling for $\Sigma_g$ – see [3] for more discussion. The relevance of consistency here is the following.

**Proposition 4.1** ([3]). If $\Delta$ is consistent then two paths $u_1, u_2$ in $Q$ from $i$ to $j$ are equal in $\text{Jac}(CQ_\Delta, W_\Delta)$ if and only if they are homotopic in $\Sigma_g \times S^1$.

Pick a maximal tree $T \subset Q_\Delta$, and let $(\Sigma_g \times S^1)'$ be obtained by contractung $\iota(T)$ to a point. The natural map $\pi_1((\Sigma_g \times S^1)) \to \pi_1((\Sigma_g \times S^1)')$ is an isomorphism. The above proposition states that if $\Delta$ is consistent then the resulting map $e_i \text{Jac}(CQ_\Delta, W_\Delta) e_j \to \mathbb{C}[\pi_1((\Sigma_g \times S^1)')]$ is injective for all $i, j \in (Q_\Delta)_0$, and we obtain an embedding depending on our choice of $T$

$$t_\Delta : \text{Jac}(CQ_\Delta, W_\Delta) \subset \text{Mat}_{r \times r}(\mathbb{C}[\pi_1(\Sigma_g \times S^1)]),$$

where $r = |(Q_\Delta)_0|$.

**Proposition 4.2.** Let $\Delta$ be an arbitrary brane tiling of $\Sigma_g$, and localize with respect to the pair $Q_\Delta \subset Q_\Delta$. Then there is an isomorphism

$$\text{Jac}(\widehat{CQ_\Delta}, W_\Delta) \cong \text{Mat}_{r \times r}(\mathbb{C}[\pi_1(\Sigma_g \times S^1)]).$$

**Proof.** We extend $t_\Delta$ to a map $\text{Jac}(\widehat{CQ_\Delta}, W_\Delta) \to \text{Mat}_{r \times r}(\mathbb{C}[\pi_1(\Sigma_g \times S^1)])$. It is not hard to check that this map is surjective; we show injectivity. If $t_\Delta(p) = t_\Delta(p')$ for two paths $p$ and $p'$ in $Q_\Delta$ starting at $i \in (Q_\Delta)_0$, then $t_\Delta(p^{-1}p') = e_{ii}$, the elementary matrix with entry 1 in the $(i, i)$th place and zeros elsewhere. But $p^{-1}p' = e_\lambda^i$ in $\text{Jac}(\widehat{CQ_\Delta}, W_\Delta)$ for some $\lambda$, by [3] Lem.2.7], from which we deduce that $\lambda = 0$ and $p = p'$ in $\text{Jac}(\widehat{CQ_\Delta}, W_\Delta)$. \hfill $\square$

Note that no reference to consistency is made in Proposition 4.2. Thinking of $\text{Jac}(\widehat{CQ_\Delta}, W_\Delta)$ as an algebra with many objects, this is explained by the fact that the localized Jacobi algebra...
\( \text{Jac}(\widehat{CQ}_\Delta, W_\Delta) \) is always an integral domain with many objects, regardless of whether \( \Delta \) is consistent or not.

5. Dimensional Reduction for Brane Tiling Algebras

Recall that we always assume that \( g \geq 1 \). Let \( \Delta \) be a consistent brane tiling on \( \Sigma_g \), and let \( D^b_{fd}(\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)) \) be the subcategory of the derived category of complexes of modules over the associated Jacobi algebra consisting of complexes with finite dimensional total cohomology. Then \( D^b_{fd}(\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)) \) shares some features with \( D^b(\text{Coh}(X)) \), the bounded derived category of coherent sheaves on a smooth projective Calabi–Yau 3-fold \( X \), namely by [3 Cor.4.4] there is a natural equivalence of bifunctors

\[
\text{Ext}^i(M, N) \simeq \text{Ext}^{3-i}(N, M)^*
\]

for \( N, M \in D^b_{fd}(\text{Jac}(\mathbb{C}Q_\Delta, W_\Delta)) \). On the other hand, by Poincaré duality, \( D^b_{fd}(\mathbb{C}[\pi_1(\Sigma_g)]) \) carries a similar equivalence of bifunctors, but with a shift of 2 — the category \( D^b_{fd}(\mathbb{C}[\pi_1(\Sigma_g)]) \) has more in common with the category of coherent sheaves on a Calabi–Yau 2-fold than a 3-fold. The purpose of this section is to explain how it is, then, that the cohomology of the untwisted character stack shows up in the study of CoHAs for certain brane tiling algebras.

We use cohomological dimensional reduction of vanishing cycles, for which the setup is very general (see [1] for the motivic analogue). Let \( Y \) be a \( G \)-variety, and let \( E \) be the total space of a \( G \)-equivariant vector bundle on \( Y \). We assume that every point of \( Y \) is contained in a \( G \)-equivariant affine subvariety of \( Y \).

**Proposition 5.1.** Let \( f \) be a regular function on \( [E/G] \) that is homogeneous of weight one with respect to the scaling action of \( \mathbb{C}^* \) along the fibres of \( \pi: E \to Y \). Let \( i: [Z/G] \hookrightarrow f^{-1}(0) \) be the maximal subspace of \( f^{-1}(0) \) satisfying \( \pi^{-1}\pi([Z/G]) = [Z/G] \). Then there is a natural equivalence

\[
\Upsilon: \pi_!\varphi_f\pi^*[1] \cong \pi_!i_*i^*\pi^*: D^b(\text{MHM}([Y/G])) \to D^b(\text{MHM}([Y/G])).
\]

The proof in the case in which \( Y \) is a single affine variety is contained in the appendix of [3]. The general case is then a consequence of the fact that the statement is local on \( Y \). Applying \( ([Y/G] \to \text{pt})_! \) to \( \Upsilon(Q|_{[Y/G]}) \), we obtain

\[
H^*_c([E/G], \varphi_f) \cong H^*_c([Z/G], Q) \cong H^*_c([\pi(Z)/G], \mathbb{Q})\{\dim_{\mathbb{C}}(\pi)\}.
\]

Now let \( (Q, W) \) be a quiver with potential. A cut of \( (Q, W) \) is a set \( E \subset Q_1 \) of edges such that if we grade the edges \( Q_1 \) by setting \( |a| = 1 \) if \( a \in E \) and \( |a| = 0 \) otherwise, \( W \) is homogeneous of degree one. Let \( E \subset Q_1 \) be a cut of \( (Q, W) \), and let \( Q' \subset Q \) be a subquiver containing none of the arrows of \( E \). We define \( Q^- = Q \setminus E \) by removing the edges of \( E \), and consider the pair \( Q' \subset Q^- \), forming the localized path algebra \( \widehat{Q}^- \). We define the 2-dimensional Jacobi algebra

\[
\text{Jac}_{2d}(\widehat{CQ}, W, E) := \widehat{CQ}/(a, \partial W/\partial a|a \in E) \cong \widehat{CQ}^-/(\partial W/\partial a|a \in E).
\]

Note that although \( a \in E \) is not an element of \( \widehat{CQ}^- \), \( \partial W/\partial a \) is, by the grading conditions.
Example 5.2. Let \((Q, W)\) be the three loop quiver with potential from Example 3.7, let \(E = \{z\}\), and let \(Q' \subset Q\) be the quiver containing the two loops \(x, y\). Then \(Q^- = Q'\), and \(\widetilde{CQ^-} = \mathbb{C}(x^{\pm 1}, y^{\pm 1})\). The set \(\{\partial W/\partial a | a \in E\}\) is just \(\{xy - yx\}\), so that
\[
\text{Jac}_{2d}(\widetilde{CQ}, W, E) \cong \mathbb{C}[x^{\pm 1}, y^{\pm 1}] \cong \mathbb{C}[\pi_1((S^1)^2)]
\]

Proposition 5.3. Let \(Q' \subset Q, W, E\) satisfy the above conditions. There is an isomorphism of cohomologically graded mixed Hodge structures
\[
\Pi^*(\text{Rep}_\gamma(\text{Jac}(\widetilde{CQ}, W), \varphi_{\text{tr}(W)})) \cong \Pi^*(\text{Rep}_\gamma(\text{Jac}_{2d}(\widetilde{CQ}, W, E)), Q) \{\prod_{a \in E} \gamma_s(a) \gamma_t(a)\}.
\]

Proof. Note that \(\pi : \text{Rep}_\gamma(CQ) \to \text{Rep}_\gamma(\widetilde{CQ^-})\) is a \(\sum_{a \in E} \gamma_s(a) \gamma_t(a)\)-dimensional \(\text{GL}_r(C)\)-equivariant vector bundle, since we do not localize with respect to any of the arrows in \(E\). So we can apply Proposition 5.1 since \(\text{tr}(W)\) is a weight one function on \(\text{Rep}_\gamma(CQ)\) with respect to the scaling action of \(\pi\). We have to work out \(Z\), in the notation of Proposition 5.1. In the notation of Convention 3.2, it is enough to work out \(Z \subset \text{Rep}_\gamma(CQ)\). We write \(\text{tr}(W) = \sum x_{i,j,a} \pi^*(f_{i,j,a})\) where \(f_i\) are functions on \(\text{Rep}_\gamma(\widetilde{CQ^-})\) and the \(x_{i,j,a}\) are linear coordinates on the fibres of \(\pi\) given on a representation \(\rho \in \text{Rep}_\gamma(CQ)\) by the \((i, j)\)th entry of \(\rho(a)\), for \(a \in E\). Then \(Z = \text{locus where all the } f_{i,j,a} \text{ vanish. But } f_{i,j,a} \text{ is just the } (j, i)\text{th entry of } \partial W/\partial a(\rho)\), so \(Z\) is the locus where all the matrix valued functions \(\partial W/\partial a\) vanish, i.e. \(Z = \pi^{-1}(\text{Rep}_\gamma(\text{Jac}_{2d}(\widetilde{CQ}, W, E)))\).

Proposition 5.4. Let \(\Delta\) be a brane tiling of \(\Sigma_g\), let \(E\) be a cut of \(Q\), and let \(Q' \subset Q\) be the subquiver containing all those edges not contained in \(E\). Let \(r = |(Q\Delta)_0|\). There is an isomorphism
\[
\text{Jac}_{2d}(\tilde{CQ\Delta}, W, E) \cong \text{Mat}_{r \times r}(\mathbb{C}[\pi_1(\Sigma_g)])).
\]

Proof. There is a map \(j : \text{Jac}_{2d}(\tilde{CQ\Delta}, W, E) \to \text{Jac}(\tilde{CQ\Delta}, W)\) induced by the natural map
\[
\tilde{CQ\Delta}/\langle \partial W/\partial a | a \in E \rangle \to \text{Jac}(\tilde{CQ\Delta}, W),
\]
this is a map of nonnegatively graded algebras after placing the domain in degree zero and giving the target the grading satisfying \(|a| = 1\) for \(a \in E\), \(|a| = 0\) otherwise. The degree zero part of the Jacobi ideal \(\langle \partial W/\partial a | a \in (Q\Delta)_1 \rangle\) is exactly \(\langle \partial W/\partial a | a \in E \rangle\), considered as a two-sided ideal of \(\tilde{CQ\Delta}\), and so \(j\) is just the inclusion of the degree zero piece of \(\text{Jac}(\tilde{CQ\Delta}, W)\).

We extend \(t\Delta\) to \(\text{Jac}(\tilde{CQ\Delta}, W)\) – the extension is injective by the same argument as Prop. 4.2. Then we restrict this map to \(\text{Jac}_{2d}(\tilde{CQ\Delta}, W, E)\). The image lies in \(\text{Mat}_{r \times r}(\mathbb{C}[\pi_1(\Sigma_g \times pt)])\) since the arrows of \(Q\) have weight zero. We show that this map is surjective. For this it is enough to show that for any path \(p\) between two vertices \(i\) and \(j\) of \(Q\Delta\) there is a homotopic path in \(\tilde{Q}\). Denote \(a\) by \(a^+\) and \(a^-\) by \(a^-\). Every arrow \(a_0^\pm\) contained in \(p\) that is not contained in \(\tilde{Q}\) is contained in a minimal cycle \(c_v = a_0 a_1 \ldots a_r\). We can replace \(a_0^\pm\) by \(a^+_r \ldots a^+_1\) to obtain a homotopic path, since \(c_v\) is contractible. Note that all of \(a_1, \ldots, a_r \in \tilde{Q}\) by the condition on \(Q'\).

□
Proposition 5.5. For a finitely generated algebra $A$ there is an equivalence of Artin stacks

$$\text{Rep}_m(A) \cong \text{Rep}_m(\text{Mat}_{r \times r}(A)).$$

Proof. Say a $B \otimes \text{Mat}_{r \times r}(A)$-module $M$ is represented by a map $\text{Spec}(B) \xrightarrow{f} \text{Rep}_m(\text{Mat}_{r \times r}(A))$. Since $\text{Rep}_m(\text{Mat}_{r \times r}(A))$ is finite type, $f$ factors as $\text{Spec}(B) \xrightarrow{g} \text{Spec}(B') \xrightarrow{\delta} \text{Rep}_m(\text{Mat}_{r \times r}(A))$ with $p$ corresponding to an inclusion of a Noetherian ring $B' \subset B$, and $g$ corresponding to a $B' \otimes \text{Mat}_{r \times r}(A)$-module $M'$. Let $C_i$ be the space of $r \times r$ matrices with entries in $A$ which are zero away from the $i$th column. Since $M' \cong \bigoplus C_i \cdot M'$ is locally free as a $B'$-module it is projective, since $B'$ is Noetherian. It follows that each of the summands $C_i \cdot M'$ are projective too, so $C_i \cdot M'$ is locally free, and hence so is $C_i \cdot M \cong p^* C_i \cdot M$. So $C_i$ is a natural functor from the groupoid of $B \otimes \text{Mat}_{r \times r}(A)$ modules locally free over $B$ to the groupoid of $B \otimes A$-modules locally free over $B$, with a natural inverse sending $M$ to $M \otimes \mathbb{C}^r$ with the natural $B \otimes \text{Mat}_{r \times r}(A)$-action. \\Theorem 5.6. Let $V(\Delta)$ be the number of vertices in a brane tiling $\Delta$ of a surface $\Sigma$. Assume that $(Q_\Delta,W_\Delta)$ admits a cut $E$, and define $Q' \subset Q_\Delta$ and $\overline{CQ_\Delta}$ as in Proposition 5.4 There is an isomorphism of mixed Hodge structures

$$H_c^{*}(\text{Rep}_{(n,\ldots,n)}(\text{Jac}(\overline{CQ_\Delta},W_\Delta),\varphi_{tr(W_\Delta)})) \cong H_c^{*}(\text{Rep}_n(\mathbb{C}[\pi_1(\Sigma)],\mathbb{Q})\{V(\Delta)n^2/2\},$$

so the mixed Hodge structure $\mathcal{H}^\text{Betti}_g$ of $[3]$ carries the structure of a localized Hopf algebra in the category of cohomologically graded mixed Hodge structures.

Proof. For the first statement, put together Propositions 5.3, 5.4 and 5.5 and observe that $|E| = V(\Delta)/2$. For the second we use the construction of Section 3, noting the degree shift by $\dim_{\mathbb{C}}(\text{Rep}_{(n,\ldots,n)}(\overline{CQ}))/2$ in [12], Remark 3.2 and the calculation

$$V(\Delta)n^2 - \dim_{\mathbb{C}}(\text{Rep}_{(n,\ldots,n)}(\overline{CQ})) = V(\Delta)n^2 - (|Q_1|n^2 - |Q_0|n^2) = (2 - 2g)n^2.$$ 

See [4] for a construction of such a $(Q_\Delta,W_\Delta)$ for $g \geq 1$. \\6. Conclusion and further directions

It is striking that the shift in the relation [7] is exactly the shift required to turn the dual compactly supported cohomology of untwisted character stacks into a CoHA. It leads naturally to the following conjecture (suggested by Olivier Schiffmann), which would imply Conjecture 1.1.

Conjecture 6.1. There is a Lie algebra structure on $\bigoplus_{n \geq 1} H_c(\mathcal{M}_{g,n}^{\text{Betti, tw}},\mathbb{Q})\{(1-g)n^2\}^*$, and a filtration $Y$ on $\mathcal{H}^\text{Betti}_g$ such that there is an isomorphism of algebras

$$\text{Gr}_Y^{*}(\mathcal{H}^\text{Betti}_g) \cong U \left( \bigoplus_{n \geq 1} H_c(\mathcal{M}_{g,n}^{\text{Betti, tw}},\mathbb{Q})\{(1-g)n^2\}^*[u] \right).$$
Here \( u \) is a formal variable of weight and cohomological degree 2, and we extend the Lie bracket via \([gu^i, g'u^j] = [g, g']u^{i+j}\). The conjecture is partly motivated by analogy with the case of quiver varieties (see below, and [19 Thm.5.5.1]), and partly by relation (7), itself a consequence of Conjecture 1.1.

We finish by returning to the P=W conjecture. We say a cohomologically graded mixed Hodge structure \( L_i \) is pure if the \( i \)th graded piece \( L^i \) is pure of weight \( i \). Note that for \( k \in \mathbb{Z} \), \( L^k \{ k \} \) is pure if \( L^k \) is. Furthermore, since \( \text{Gr}^W_1(H^i_c(X, \mathbb{Q})) = 0 \) for \( X \) smooth and \( j > i \), it follows from the long exact sequence in compactly supported cohomology that \( \text{Gr}^W_1(H^i_c(X, \mathbb{Q})\{k\}) = 0 \), for all schemes \( X \) and all values of \( k \) and \( j > i \). Since the multiplication and comultiplication in \( \mathcal{H}_g^{\text{Betti}} \) are morphisms of cohomologically graded mixed Hodge structures, it follows that there is a sub localized bialgebra of pure cohomology \( \text{Pure}(\mathcal{H}_g^{\text{Betti}}) \subset \mathcal{H}_g^{\text{Betti}} \). From Conjecture 1.1, the conjectural form for the mixed Hodge polynomials of \( \mathcal{H}_{g,n}^{\text{tw}} \) given in [13 Conj.4.2.1], and [20 Thm.5.1], we obtain the following prediction:

\[
\text{E}(\text{Pure}(\mathcal{H}_g^{\text{Betti}})) = \text{E}(H_c([\mu_{n,g}^{-1}(0)/\text{GL}_n(\mathbb{C})], \mathbb{Q})\{(1-g)n^2\})
\]

where \( \mu_{n,g} : \text{Mat}_{n \times n}(\mathbb{C})^{x2g} \rightarrow \text{Mat}_{n \times n}(\mathbb{C}) \) is given by \( \sum_{j=1}^g [A_j, B_j] \).

Eq. (16) illustrates the main point of this paper: Conjecture 1.1 gives a way to translate conjectures regarding the cohomology of twisted character varieties into very different, but equivalent, conjectures regarding the cohomology of their untwisted counterparts. Eq. (16) is the untwisted cousin of the purity conjecture of [13 Rem.4.4.2].

Let \( x \in X \) be a point of an algebraic variety. Recall the deformation to the normal cone of \( x \) in \( X \) (see [3 Ch.5]): there is a map \( f : Y \rightarrow A^1_\mathbb{C} \) such that the pullback along the inclusion \( A^1_\mathbb{C} \setminus \{0\} \rightarrow A^1_\mathbb{C} \) is the trivial family with fibre \( X \), and the normal cone \( N_x \) to \( x \) embeds into the fibre \( Y_0 \) as an open subvariety. It follows that \( H_c(Y, \psi_f) \cong H_c(X, \mathbb{Q}) \), and we have a composition of morphisms \( H_c(N_x, \mathbb{Q}) \rightarrow H_c(Y_0, \mathbb{Q}) \rightarrow H_c(X, \mathbb{Q}) \), the first coming from the open inclusion, the second coming from the map (10). This construction gives a natural categorification of (16) (in other words a map to underly the conjectural equality of generating series) suggested by Tamás Hausel. The normal cone to \( \mathbb{1}^{\oplus n} \in \text{Rep}_n(\mathbb{C}[\pi_1(\Sigma_g)]) \) is precisely \( [\mu_{n,g}^{-1}(0)/\text{GL}_n(\mathbb{C})] \), giving the map

\[
\Psi : \mathcal{H}_g^{\text{Betti}} \rightarrow \bigoplus_n H_c([\mu_{n,g}^{-1}(0)/\text{GL}_n(\mathbb{C})], \mathbb{Q})\{(1-g)n^2\}^\ast.
\]

**Conjecture 6.2.** The map \( \Psi \) is an isomorphism after restricting to \( \text{Pure}(\mathcal{H}_g^{\text{Betti}}) \).

So far it is known at least that \( \Psi \) is a retraction when \( g = 1 \) – this is easy to see after observing that there is an open embedding \( \text{Rep}_n(\mathbb{C}[\pi_1(\Sigma_1)]) \subset [\mu_{n,1}^{-1}(0)/\text{GL}_n(\mathbb{C})] \) that takes \( \mathbb{1}^{\oplus n} \) to the vertex of the cone \( [\mu_{n,1}^{-1}(0)/\text{GL}_n(\mathbb{C})] \). The cohomological Hall algebra that is the target of \( \Psi \) is itself the object of study from various directions, and is the object of interest when making the link with the work of Maulik and Okounkov [19] and, separately, Schiffmann and Vasserot [23] on the construction of Yangians associated to Nakajima quiver varieties.

We finally come to the P=W conjecture. On the Higgs bundle side, the map (17) has a natural analogue, given by deformation to the normal cone of the point \((\mathcal{O}^{\oplus n}_C, 0) \in \mathcal{M}^{\text{Betti}}_{n,1}(C)\), the stack of degree zero semistable Higgs bundles. By converting the problem to degree zero
(the equivalent move on the Higgs bundle side to moving attention from twisted to untwisted character varieties) we arrive at a conjectural geometric description of the lowest perversity part of the cohomology of the stack of semistable Higgs bundles. In conclusion, we arrive at a new way of understanding the pure part of the P=W conjecture, as well as relating both sides of nonabelian Hodge theory to the theory of BPS state counting in noncommutative geometry.
