Special reductive groups over an arbitrary field

Mathieu Huruguen

Abstract

A linear algebraic group $G$ defined over a field $k$ is called special if every $G$-torsor defined over a field extension of $k$ is trivial. In 1958 Grothendieck classified special groups in the case where the base field is algebraically closed. In this paper we describe the derived subgroup and the coradical of a special reductive group over an arbitrary field $k$. We also classify special semisimple groups, special reductive groups of inner type and special quasisplit reductive groups over an arbitrary field $k$.

1 Introduction

Let $k$ be a base field and $G$ an algebraic group defined over $k$. The group $G$ is called special if every $G$-torsor defined over a field extension of $k$ is trivial. In other words, if for every field extension $K$ of $k$ the first fppf-cohomology set $H^1(K, G)$ contains only one element. Examples of special linear groups include the additive group $G_a$, the multiplicative group $G_m$, the general linear group $GL_n$, and more generally the group $GL_1(A)$, where $A$ is a central simple algebra over $k$, and the classical groups $SL_n$ and $Sp_{2n}$. In contrast, the group $SO_n$ is not special for $n \geq 3$. The special groups over an algebraically closed field were introduced by Serre in [12] - recently reprinted in [14]. In this paper, Serre gave the basic properties of special groups, for example, he showed that they are linear and connected. The study of special groups over an algebraically closed field was then completed by Grothendieck in [5]. In the reductive case, his result can be stated as follows:

**Theorem 1.1** (Grothendieck, 1958). Suppose that $G$ is reductive and $k$ is algebraically closed. Then $G$ is special if and only if its derived subgroup is isomorphic to a direct product

$$G_1 \times G_2 \times \cdots \times G_r$$

where, for each $i$, the group $G_i$ is isomorphic to $SL_{n_i}$ or $Sp_{2n_i}$, for some integer $n_i$.

The result of Grothendieck naturally raises the problem of classifying special reductive groups over an arbitrary field $k$. The present paper is an attempt to solve this problem. Our most general classification result is the following:
Theorem 1.2. Let $G$ be a reductive algebraic group over $k$. Then $G$ is special if and only if the three following conditions hold:

1. The derived subgroup of $G$ is isomorphic to

$$R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$

where, for each index $i$, the extension $K_i$ of $k$ is finite and separable, $R_{K_i|k}$ denotes the Weil scalar restriction functor - see for example [6, Lemma 20.6] - and the group $G_i$ is isomorphic over $K_i$ to either $SL_1(A_i)$, where $A_i$ is a central simple algebra over $K_i$, or $Sp_{2n_i}$ for some integer $n_i$.

2. The coradical of $G$ is a special torus.

3. For every field extension $K$ of $k$, we have

$$\text{Im}(\alpha_{G',K}) + \text{Ker}(H^1(K, Z_{G'}) \to H^1(K, Z_G)) = H^1(K, Z_{G'})$$

where $Z_G$ is the center of $G$, $Z_{G'}$ is the center of its derived subgroup $G'$, and the map $\alpha_{G',K}$ is defined in [27].

Condition (1) above is explicit, as well as condition (2), by the classification of special tori due to Colliot-Thélène and recalled at the end of the present paper. In contrast, condition (3) is not very explicit in general. However, under some additional assumptions on the group $G$, namely that $G$ is semisimple, an inner form of a Chevalley group, or quasisplit, we are able to make condition (3) completely explicit, providing the classification in these cases. We hope that an explicit version of condition (3) will emerge in the future, unifying these cases and providing the classification of special reductive groups.

The paper is organized as follows. In Section 2 we gather some facts to be used in the following sections. In Section 3 we determine which algebraic groups can arise as derived subgroups of a special group and which can arise as coradicals, respectively in Proposition 3.2 and 3.4. In Section 4 we prove our general classification result stated above and then derive from it the classification of special semisimple groups, special reductive groups of inner type and special quasisplit groups in Proposition 4.2, 4.4 and 4.6 respectively. Finally, we recall in Section 5 the classification of special tori due to Colliot-Thélène.

To finish this introduction, we say a word about special non-reductive groups. First, by [10, Lemma 1.13], if an algebraic group $G$ over a field $k$ possesses a $k$-split unipotent normal subgroup $U$, then $G$ is special if and only if $G/U$ is special. For example, if the field $k$ is perfect, then $G$ is special if and only if its quotient by the unipotent radical - which is a reductive group - is special, as every unipotent group over $k$ is $k$-split. On a different note, Nguyen classifies special unipotent groups over “reasonable fields” in [8]. It is a direct consequence of the fact that the additive group $G_a$ is special that every $k$-split unipotent group is special. In [8], Nguyen proves conversely that a special unipotent group is $k$-split for certain fields $k$, for example when $k$ is finitely generated over a perfect field.
Acknowledgment

I would like to warmly thank Zinovy Reichstein for pointing out this problem to me, for very interesting discussions on this topic and also for remarks which helped improving the exposition of this paper. I would also like to thank Roland L{"o}tscher for bringing reference [8] to my attention.

2 Preliminary results

Let $k$ be a base field and $G$ a reductive algebraic group defined over $k$. Throughout the paper we denote by $Z_G$ the center of $G$, by $G_{\text{ad}}$ the adjoint quotient $G/Z_G$ of $G$, by $G'$ the derived subgroup of $G$, by $R_G$ the radical of $G$ and by $C_G$ its coradical. We have an exact sequence of algebraic groups:

$$1 \rightarrow Z_G \rightarrow G \rightarrow G_{\text{ad}} \rightarrow 1 \quad (*)$$

Definition 2.1. Let $K$ be a field extension of $k$. We denote by

$$\alpha_{G,K} : G_{\text{ad}}(K) \rightarrow H^1(K, Z_G) \text{ and } \beta_{G,K} : H^1(K, G_{\text{ad}}) \rightarrow H^2(K, Z_G)$$

the connecting maps in fppf-cohomology obtained from the exact sequence $(*)$ above.

Proposition 2.2. The group $G$ is special if and only if for every field extension $K$ of $k$, the map $\alpha_{G,K}$ is surjective and the map $\beta_{G,K}$ has trivial kernel.

Proof. Part of the exact sequence of pointed sets obtained from the exact sequence $(*)$ reads:

$$G_{\text{ad}}(K) \xrightarrow{\alpha_{G,K}} H^1(K, Z_G) \rightarrow H^1(K, G) \rightarrow H^1(K, G_{\text{ad}}) \xrightarrow{\beta_{G,K}} H^2(K, Z_G)$$

It is a straightforward consequence of the exactness of this sequence of pointed sets that $H^1(K, G)$ is trivial if and only if $\alpha_{G,K}$ is surjective and $\beta_{G,K}$ has trivial kernel.

Proposition 2.3. Let $K$ be a field extension of $k$. If $G$ is special then the following properties hold:

1. the map
$$\beta_{G',K} : H^1(K, (G')_{\text{ad}}) \rightarrow H^2(K, Z_{G'})$$

has trivial kernel.

2. the image of the map $\beta_{G',K}$ intersects the kernel of the morphism
$$H^2(K, Z_{G'}) \rightarrow H^2(K, Z_G)$$

trivially.
(3) the following exact sequence of diagonalizable groups

\[ 1 \rightarrow Z_{G'} \rightarrow Z_G \rightarrow Z_G/Z_{G'} \rightarrow 1 \quad (\ast\ast) \]

induces the following exact sequence in fppf-cohomology:

\[ 0 \rightarrow H^1(K, Z_G/Z_{G'}) \rightarrow H^2(K, Z_{G'}) \rightarrow H^2(K, Z_G) \]

Proof. We will obtain these properties from Proposition 2.2 and the fact that the adjoint groups \((G')_{\text{ad}}\) and \(G_{\text{ad}}\) are equal. The inclusion of \(G'\) in \(G\) gives rise to a natural commutative diagram:

\[
\begin{array}{cccccc}
1 & \rightarrow & Z_{G'} & \rightarrow & G' & \rightarrow & (G')_{\text{ad}} & \rightarrow & 1 \\
\downarrow & & \downarrow & & || & & \\
1 & \rightarrow & Z_G & \rightarrow & G & \rightarrow & G_{\text{ad}} & \rightarrow & 1
\end{array}
\]

where both rows are exact. The diagram above leads to a commutative diagram of connecting maps in fppf-cohomology:

\[
\begin{array}{ccc}
\beta_{G',K} & H^2(K, Z_{G'}) \\
\downarrow & \downarrow \\
H^1(K, G_{\text{ad}}) & \beta_{G,K} & H^2(K, Z_G)
\end{array}
\]

where the vertical map is induced by the inclusion of \(Z_{G'}\) in \(Z_G\). As \(G\) is special, by Proposition 2.2, the map \(\beta_{G,K}\) has trivial kernel, which readily implies (1) and (2).

To prove (3) we look at the following diagram in fppf-cohomology:

\[
\begin{array}{ccc}
\alpha_{G',K} & H^1(K, Z_{G'}) \\
\downarrow & \downarrow \\
G_{\text{ad}}(K) & \alpha_{G,K} & H^1(K, Z_G)
\end{array}
\]

where the vertical map is induced by the inclusion of \(Z_{G'}\) in \(Z_G\). As \(G\) is special, by Proposition 2.2 we see that \(\alpha_{G,K}\) is surjective, forcing the vertical map to be surjective as well. Now, part of the long exact sequence in fppf-cohomology obtained from the short exact sequence \((\ast\ast)\) reads:

\[ H^1(K, Z_{G'}) \rightarrow H^1(K, Z_G) \rightarrow H^1(K, Z_G/Z_{G'}) \rightarrow H^2(K, Z_{G'}) \rightarrow H^2(K, Z_G) \]

and the result readily follows. \(\square\)
Proposition 2.4. Suppose that the coradical $C_G$ of $G$ is special. Then $G$ is special if and only if, for every field extension $K$ of $k$, the following two conditions hold:

1. $\text{Im}(\alpha_{G',K}) + \ker(H^1(K, Z_{G'}) \to H^1(K, Z_G)) = H^1(K, Z_{G'})$

2. The map
   $$\beta_{G',K}: H^1(K, (G')_{\text{ad}}) \to H^2(K, Z_{G'})$$
   has trivial kernel.

Proof. The coradical $C_G$ is equal to $Z_G/Z_{G'}$. As it is special, we know that the morphism
   $$H^1(K, Z_{G'}) \to H^1(K, Z_G)$$
is surjective. Therefore, by the commutative diagram:

```
\begin{array}{ccc}
G_{\text{ad}}(K) & \xrightarrow{\alpha_{G',K}} & H^1(K, Z_{G'}) \\
\downarrow \alpha_{G,K} & & \downarrow \\
H^1(K, Z_G) & & 
\end{array}
```

we see that (1) is equivalent to $\alpha_{G,K}$ being surjective. Similarly, because the coradical $C_G$ is special, we know that the morphism
   $$H^2(K, Z_{G'}) \to H^2(K, Z_G)$$
induced by the inclusion is injective. Therefore, by the commutative diagram:

```
\begin{array}{ccc}
H^1(K, G_{\text{ad}}) & \xrightarrow{\beta_{G',K}} & H^2(K, Z_{G'}) \\
\downarrow \beta_{G,K} & & \downarrow \\
H^2(K, Z_G) & & 
\end{array}
```

we see that (2) is equivalent to the fact that $\beta_{G,K}$ has a trivial kernel. We can conclude that $G$ is special by Proposition 2.2.

\[\square\]

3 The derived subgroup and the coradical of a special reductive group

In this section we will determine which algebraic groups can arise as derived subgroups of a special reductive group and which can arise as coradicals respectively in Proposition 3.2 and 3.3 below.
### 3.1 A lemma on hermitian forms

In order to lighten the proof of Proposition 3.2, we start by proving Lemma 3.1 below about hermitian forms. We refer the reader to [6, §4] for the definition of hermitian forms on a right module over an algebra $D$ equipped with an involution.

Let $D$ be a division algebra, $k$ a subfield of its center and $\tau$ an involution of $D$. Let $n$ be an integer and $t_1, \ldots, t_n$ be algebraically independent variables over $k$. We denote by $K$ be the field of fractions $k(t_1, \ldots, t_n)$. We fix an integer $m$, a collection of scalars $\alpha_1, \ldots, \alpha_n$ in $k^*$ and, for every index $i$ between 1 and $m$, we fix an element $a_i = (a_{i,1}, \ldots, a_{i,n})$ of $\mathbb{Z}^n$.

**Lemma 3.1.** Suppose that the images of the $a_i$'s in $(\mathbb{Z}/2\mathbb{Z})^n$ are all different. Then, the hermitian form:

$$h(x, y) = \sum_{i=1}^{m} \alpha_i t_1^{a_{i,1}} \ldots t_n^{a_{i,n}} \tau(x_i) y_i$$

is anisotropic on $(D \otimes_k K)^m$.

**Proof.** The proof goes along the same line as [9, p.111]. Suppose that there exists an isotropic vector $x$. By clearing the denominator we can further assume that all the coordinates $x_i$ of $x$ belong to $D \otimes_k k[t_1, \ldots, t_n]$. Now, as a consequence of our assumption, we see that the leading monomials of the Laurent polynomials

$$\alpha_i t_1^{a_{i,1}} \ldots t_n^{a_{i,n}} \tau(x_i) x_i$$

with respect to the lexicographic order are all different when $i$ ranges from 1 to $m$. Therefore they cannot cancel. \qed

### 3.2 The derived subgroup of a special reductive group

We will use [6, §26] as a basic reference for the classification of algebraic groups over non-algebraically closed fields. We will adopt the notations of [6] throughout.

**Proposition 3.2.** Let $G$ be a special reductive algebraic group over $k$. The derived subgroup of $G$ is isomorphic to

$$R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$

where, for each $i$, the extension $K_i$ of $k$ is finite and separable and the group $G_i$ is isomorphic over $K_i$ to either $\text{SL}_1(A_i)$, where $A_i$ is a central simple algebra over $K_i$, or $\text{Sp}_{2n_i}$ for some integer $n_i$.

**Proof.** By Theorem 1.1, the group $G'_k$, where $\overline{k}$ is an algebraic closure of $k$, is a semisimple simply connected group whose simple components are of type A and C. Therefore, by [6, Theorem 26.8], the group $G'$ is isomorphic to a direct product

$$R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$
where, for each index $i$, the extension $K_i$ of $k$ is finite and separable and the group $G_i$ is an absolutely simple simply connected group over $K_i$ of type A or C. For each index $i$, $G_i$ is a direct factor of the derived subgroup of the special reductive group $G_{K_i}$. By Proposition 2.3 we get that the map $\beta_{G_{K_i}, K}$ has trivial kernel for every field extension $K$ of $K_i$, which readily implies that the map $\beta_{G_i, K}$ has trivial kernel as well. This forces $G_i$ to be of inner type A or split of type C, by Lemma 3.3 below, completing the proof of the proposition.

**Lemma 3.3.** Let $G$ be an absolutely simple simply connected group of type A or C over the field $k$. If, for every field extension $K$ of $k$, the map $\beta_{G,K}$ has a trivial kernel, then $G$ is either of inner type A or split of type C.

**Proof of Lemma 3.3.** Suppose first that $G$ is of outer type A. We will prove that the kernel of $\beta_{G,K}$ contains at least two elements for some field extension $K$ of $k$. Observe that to prove this property we can replace $G$ by $G_M$ for some scalar extension $M$ of $k$. By [6, §26], $G$ is isomorphic to $SU(A, \sigma)$, where $A$ is a central simple algebra of degree $n$ - at least 3, otherwise $SU(A, \sigma)$ is of inner type - over a quadratic separable extension $L$ of $k$ equipped with an involution $\sigma$ of the second kind.

We will now reduce to the case where $A$ is split over $L$. To this aim, we denote by $Y$ the Severi-Brauer variety of $A$, by $X$ the Weil scalar restriction of $Y$ from $L$ to $k$. As $X$ is geometrically integral, the field $k$ is algebraically closed in $K$, and consequently $K \otimes_k L$ is a field. Moreover, the set $Y(K \otimes_k L)$ is not empty, as it is equal to $X(k)$. This implies that the field extension $K \otimes_k L$ of $L$ is a splitting field for $A$. Now, we observe that the group $G_K$ is isomorphic to $SU(K \otimes_k A, \sigma_K)$, where $K \otimes_k A$ is a split central simple algebra over $K \otimes_k L$ equipped with an involution $\sigma_K$ of the second kind. It is thus of outer type A and satisfies moreover the property that for every field extension $M$ of $K$, the map $\beta_{G_K,M}$ has trivial kernel. Therefore, by replacing $k$ by $K$ and $G$ by $G_K$, we are reduced to the case where the central simple algebra $A$ is split over $L$.

Then $A$ is isomorphic to $\text{End}_L(L^n)$ for some integer $n$ greater or equal to three, and the involution $\sigma$ is adjoint to a nonsingular hermitian form $h$ on $L^n$, by [6, §26]. The group $G$ is therefore isomorphic to $SU_L(n, h)$. Its center is the group $\mu_{n[L]}$, the kernel of the norm map:

$$N_{L|k} : R_{L|k}(\mu_{n,L}) \longrightarrow \mu_{n,k}$$

Let $K$ be the field $k(t_1, \ldots, t_{n-1})$ where the $t_i$s are algebraically independent variables over $k$.

We claim that the kernel of $\beta_{G,K}$ contains at least two elements. We have an exact sequence of pointed sets:

$$H^1(K, \mu_{n[L]}) \longrightarrow H^1(K, G) \longrightarrow H^1(K, G_{\text{ad}}) \xrightarrow{\beta_{G,K}} H^2(K, \mu_{n[L]})$$
in the fppf-cohomology. As \( \mu_{n[L]} \) is abelian and central in \( G \), there is a natural action of \( H^1(K, \mu_{n[L]}) \) on \( H^1(K, G) \), and the set of orbits for this action is precisely the kernel of \( \beta_{G,K} \). By [6, Example 29.19], the set \( H^1(K, G) \) is in natural correspondence with the set of isometry classes of nonsingular hermitian forms on the vector space \((K \otimes_k L)^n\) with the same discriminant \( \alpha \) as \( h \). Moreover, by [6, Proposition 30.13], the group \( H^1(K, \mu_{n[L]}) \) is the quotient of 

\[
\{(x, y) \in K^* \times (K \otimes_k L)^*, \quad x^n = N_{K \otimes_k L/K}(y)\}
\]

by the subgroup 

\[
\{(N_{K \otimes_k L/K}(z), z^n), \quad z \in (K \otimes_k L)^*\}.
\]

Strictly speaking, the description above is given in [6, Proposition 30.13] only when \( n \) is not divisible by the characteristic of the base field \( k \). This comes from the fact that the cohomology considered there is the Galois cohomology. The same proof leads to the description in the fppf-cohomology, with no restriction on the integer \( n \). It is then easy to prove that the action of the class \([x, y]\) on the isometry class \([h']\) of the hermitian form \( h' \) is given as follows:

\[
[(x, y)] \cdot [h'] = [xh'].
\]

We will now prove that the set \( H^1(K, G) \) contains the isometry class of an isotropic form and an anisotropic form. As these two classes cannot be in the same orbit under the action of \( H^1(K, \mu_{n[L]}) \), this proves the claim above.

First, as \( n \) is greater than 2, \( H^1(K, G) \) contains the isometry class of an isotropic hermitian form, namely the one with matrix 

\[
\text{diag} \left( \begin{array}{cc} 0 & 1 \\ 1 & 0 \end{array} \right), 1, \ldots, 1, -\alpha).
\]

Moreover, by Lemma 3.1 above, the hermitian form:

\[
h'(x_1, \ldots, x_n) = t_1\sigma(x_1)x_1 + \cdots + t_{n-1}\sigma(x_{n-1})x_{n-1} + \alpha t_1 \cdots t_{n-1}\sigma(x_n)x_n
\]

which has discriminant \( \alpha \), is anisotropic over the field \( K \otimes_k L \).

Suppose now that \( G \) is of type C and not split. Again here, we want to see that the kernel of \( \beta_{G,K} \) contains at least two elements for some field extension \( K \) of \( k \). By [6, §26], \( G \) is isomorphic to \( \text{Sp}(A, \sigma) \), where \( A \) is a non-split central simple algebra of degree \( 2n \) - at least 4, otherwise \( \text{Sp}(A, \sigma) \) is of type A - over \( k \) equipped with an involution \( \sigma \) of symplectic type. The center of \( G \) is isomorphic to \( \mu_2 \). Let \( K \) be a field extension of \( k \). By [6, (29.22)] the kernel of \( \beta_{G,K} \) is in bijection with the conjugacy classes of involutions of symplectic type on \( A_K \).

If \( A \) is a division algebra, then by [7, Theorem 3.1], there are more than one conjugacy classes of involutions of symplectic type on \( A_K \). From now on, we suppose that \( A \) is not a division algebra. Let \( D \) be the division algebra Brauer equivalent to \( A \). It is not \( k \), as \( A \) is non-split. Therefore, \( D \) carries an involution \( \tau \) of symplectic type, by [6, Theorem 3.1] and [6, Corollary 2.8], and, by Wedderburn’s
Let $K$ be the field of fractions $k(t_1, \cdots, t_n)$ on $n$ indeterminates. The algebra $D_K$ is a division algebra, and is therefore the division algebra Brauer equivalent to $A_K$. Let $M$ be a simple right $A_K$-module, isomorphic to $D_K^n$ - thought of as column vectors. We will make use of the correspondence between involutions of symplectic type on $A_K$ and hermitian forms on $M$, as explained in [6, Theorem (4.2)]. We refer the reader to [6, §4] for the notion of singular hermitian form and alternating hermitian form in characteristic 2. We define two hermitian forms $h$ and $h'$ on $M$ in the following way:

$$h(x, y) = -\tau(x_1)y_1 + \sum_{i=2}^{s} \tau(x_i)y_i$$

and

$$h'(x, y) = \sum_{i=1}^{s} t_i \tau(x_i)y_i$$

These forms are easily seen to be nonsingular. Furthermore, if the characteristic of $k$ is 2, then $h$ and $h'$ are alternating. Indeed, by [6, Proposition 2.6], as $\tau$ is an involution of symplectic type on $D_K$ we know that $K$ is contained in Symd$(D_K, \tau)$, which is enough to prove that for every $x$ in $M$, the elements $h(x, x)$ and $h'(x, x)$ both belong to Symd$(D_K, \tau)$.

By [6, Theorem (4.2)], the hermitian forms $h$ and $h'$ give rise to two involutions $\tau_h$ and $\tau_{h'}$ on $A_K$ which are both of symplectic type. If these two involutions were conjugate, then it would exist an element $u$ of GL$_n(D_K)$ such that the hermitian forms $h'$ and the hermitian form:

$$M \times M \rightarrow D \quad (x, y) \mapsto h(u(x), u(y))$$

are proportional by a factor in $K^*$. But $h$ is isotropic, for instance, $(1, 1, 0, \cdots, 0)$ is an isotropic element, and $h$ is not by Lemma 3.1. This provides a contradiction, proving that the involutions $\tau_h$ and $\tau_{h'}$ are not conjugate.

Observe that every group admitting a direct factor decomposition as in Proposition 3.2 occurs as the derived subgroup of a special reductive group. Indeed, a semi-simple group

$$R_{K_i|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$

where, for each $i$, the extension $K_i$ of $k$ is finite and separable and the group $G_i$ is isomorphic over $K_i$ to either SL$_1(A_i)$, where $A_i$ is a central simple algebra over $K_i$, or Sp$_{2n_i}$ for some integer $n_i$, is the derived subgroup of the special reductive group

$$R_{K_i|k}(H_1) \times R_{K_2|k}(H_2) \times \cdots \times R_{K_r|k}(H_r)$$

where, for each index $i$, $H_i$ is equal to GL$_1(A_i)$ if $G_i$ is isomorphic to SL$_1(A_i)$, and $H_i$ is equal to $G_i$ otherwise.
3.3 The coradical of a special reductive group

We prove now that the coradical of a special reductive group is a special torus. The classification of special tori, due to Colliot-Thélène, will be recalled in Section 5 below.

**Proposition 3.4.** Let \( G \) be a special reductive algebraic group defined over \( k \). The coradical \( C_G \) of \( G \) is a special torus.

**Proof.** We say that a reductive algebraic group \( G \) defined over a field - which is not necessarily \( k \) - satisfies property \((P)\) if, for every field extension \( K \) of the field of definition of \( G \) and every non trivial element \( x \) in \( H^2(K, Z_G) \), there exists a field extension \( L \) of \( K \) such that \( x_L \) is not trivial in \( H^2(L, Z_G) \) and belongs to the image of \( \beta_{G,L} \). We will prove as a consequence of Lemma 3.5 below that the derived subgroup \( G' \) of \( G \) - and more generally any group admitting a direct factor decomposition as in Proposition 3.2 - satisfies property \((P)\).

Before proving this fact let us show how it implies the proposition. The coradical \( C_G \) of \( G \) is equal to the quotient \( Z_G/Z_G' \). Suppose that \( C_G \) is not special. There exists a field extension \( K \) of \( k \) and a nontrivial element \( x \) in \( H^1(K, C_G) \) - by Proposition 2.3, the image of \( x \) in \( H^2(K, Z_{G'}) \) - still denoted \( x \) - is nonzero, and is mapped to zero in \( H^2(K, Z_G) \). As the group \( G' \) satisfies property \((P)\), we can even assume, after possibly extending scalars, that there exists \( y \) in \( H^1(K, (G')_{ad}) \) such that \( x = \beta_{G',K}(y) \). We get that \( y \) is not trivial and is in the kernel of \( \beta_{G,K} \), a contradiction to Proposition 2.2.

Now, the fact that any group admitting a direct factor decomposition as in Proposition 3.2 satisfies property \((P)\) is a direct consequence of Lemma 3.5 below. In this lemma, we say that that a set of reductive algebraic groups - not necessarily defined over the same base field - is stable under Weil scalar restriction if for every field \( k \), for every finite separable field extension \( K \) of \( k \) and for every reductive algebraic group \( G \) defined over \( K \) in the set the group \( R_{K|k}(G) \) belongs to the set as well.

**Lemma 3.5.** The set of reductive algebraic groups satisfying property \((P)\) :

1. contains \( SL_1(A) \) for every central simple algebra \( A \) over a field \( k \).
2. contains \( Sp_{2n} \), for every integer \( n \) and every field \( k \).
3. is stable under finite direct products.
4. is stable under Weil scalar restrictions.

**Proof of Lemma 3.5.** Let \( k \) be a field and \( A \) a central simple algebra over \( k \). The center of \( SL_1(A) \) is \( \mu_n \), where \( n \) is the degree of \( A \). Let \( K \) be a field extension of \( k \) and \( x \) a nontrivial element of \( H^2(K, \mu_n) \). The element \( x \) is the Brauer class of a central simple algebra \( B \) over \( K \) of period \( d \) dividing \( n \), \( d \) being greater than 1. By the Schofield-Van den Bergh index reduction formula [11, Theorem 2.5], there exists a field extension \( L \) of \( K \) such that \( B_L \) is a central simple algebra over \( L \) of index \( d \). This proves that the class \( x_L \) is not trivial in \( H^2(L, \mu_n) \) because \( d \) is not
1, and belongs to the image of $\beta_{\text{SL}_1(A),L}$, this image being precisely the classes of index dividing $n$. We have proved (1).

The proof of (2) is similar. Let $k$ be a field and $n$ an integer. The center of $\text{Sp}_{2n}$ is $\mu_2$. Let $K$ be a field extension of $k$ and $x$ a nontrivial element of $H^2(K,\mu_2)$. The element $x$ is the Brauer class of a central simple algebra $B$ over $K$ of period 2. Applying the index reduction formula once again, there exists a field extension $L$ of $K$ such that $B_L$ is a central simple algebra over $L$ of index 2. This proves that the class $x_L$ is not trivial in $H^2(L,\mu_2)$, and belongs to the image of $\beta_{\text{Sp}_{2n},L}$, this image being precisely the classes of index dividing $2n$.

Let $k$ be a field. We will now prove that if $G_1$ and $G_2$ are reductive algebraic groups both satisfying property $(P)$, then the direct product $G_1 \times G_2$ satisfies property $(P)$ as well. Let $K$ be a field extension of $k$ and $x$ be a nontrivial element of

$$H^2(K,Z_{G_1 \times G_2}) = H^2(K,Z_{G_1}) \times H^2(K,Z_{G_2}).$$

We write $x = (x_1,x_2)$. As $G_1$ satisfies property $(P)$, there exists a field extension $L_1$ of $K$ such that $(x_1)_{L_1}$ is not trivial and belongs to the image of $\beta_{G_1,L_1}$. If $(x_2)_{L_1}$ is trivial then we are done. Otherwise, as $G_2$ satisfies property $(P)$, there exists a field extension $L_2$ of $L_1$ such that $(x_2)_{L_2}$ is not trivial and belongs to the image of $\beta_{G_2,L_2}$. As $(x_1)_{L_2}$ belongs to the image of $\beta_{G_1,L_2}$, we see that $x_{L_2}$ is not trivial and belongs to the image of $\beta_{G_1 \times G_2,L_2}$. This completes the proof of (3).

Let $k$ be a field, $M$ a finite separable field extension of $k$, and let $G$ be reductive algebraic group over $M$ which satisfies property $(P)$. We will now prove that the group $R_{M/k}(G)$ satisfies property $(P)$ as well. We denote by $d$ the degree of the field extension $M$ of $k$. Let $K$ be a field extension of $k$. We can write

$$K \otimes_k M = K_1 \times \cdots \times K_s$$

where the $K_i$s are finite separable extensions of $K$ and $M$. Let $x$ a nontrivial element in

$$H^2(K,Z_{R_{M/k}(G)}) = H^2(K_1,Z_G) \times \cdots \times H^1(K_s,Z_G).$$

We write $x = (x_1,\ldots,x_s)$, and we define $d_x$ to be the sum of the degrees of the $K_i$s over $k$ such that $x_i$ belongs to the image of $\beta_{G,K_i}$. The integer $d_x$ is obviously less than or equal to $d$. We prove the desired conclusion by a decreasing induction on $d_x$, the case where $d_x$ is equal to $d$ being obvious. Suppose that $d_x$ is strictly less than $d$. After permuting the $K_i$s, we can assume for example that $x_1$ is not in the image of $\beta_{G,K_1}$. In particular, $x_1$ is not trivial. As $G$ satisfies property $(P)$, there exists a field extension $L_1$ of $K_1$ such that $(x_1)_{L_1}$ is not trivial and belongs to the image of $\beta_{G,L_1}$. One then easily proves that $x_{L_1}$ is not trivial and $d_{x_{L_1}}$ is strictly greater than $d_x$. By the induction hypothesis there is a field extension $L$ of $L_1$ such that $x_L$ is not trivial and belongs to the image of $\beta_{G,L}$, completing the proof of (4).

We make now the observation that the radical of a special reductive group does not need to be special. Suppose that $K$ is a separable quadratic extension of $k$. Recall that the torus $R^1_{K/k}(\mathbb{G}_m)$ is defined as the kernel of the norm map from
\( R_{K|k}(\mathbb{G}_m) \) to \( \mathbb{G}_m \). We denote by \( R \) the direct product \( R_{K|k}(\mathbb{G}_m) \times \mathbb{G}_m \). There is an exact sequence of algebraic tori:

\[
1 \rightarrow \mu_2 \xrightarrow{\varphi} R \rightarrow R_{K|k}(\mathbb{G}_m) \rightarrow 1
\]

corresponding to the following exact sequence of \( \Gamma \)-modules, where \( \Gamma \) is the Galois group of \( K \) over \( k \):

\[
0 \rightarrow \mathbb{Z}^2 \rightarrow \mathbb{Z}^2 \rightarrow \mathbb{Z}/2\mathbb{Z} \rightarrow 0
\]

\[
(x, y) \rightarrow (x - y, x + y)
\]

\[
(x, y) \rightarrow [x + y]
\]

Here the nontrivial element of \( \Gamma \) acts on \( \mathbb{Z}^2 \) on the left by permuting the coordinates, on \( \mathbb{Z}^2 \) in the center by multiplying the first coordinate by \(-1\) and the second by \(1\), and on \( \mathbb{Z}/2\mathbb{Z} \) as the identity. We define \( G \) to be the quotient:

\[
(SL_2 \times R)/\mu_2.
\]

where \( \mu_2 \) is embedded diagonally in \( SL_2 \) and in \( R \) by using the morphism \( \varphi \) above. It is readily seen that the derived group of \( G \) is \( SL_2 \) and its coradical is \( R_{K|k}(\mathbb{G}_m) \).

An easy argument then shows that \( G \) is special, see for instance Proposition 4.6 below. However, the radical of \( G \) is equal to \( R = R_{K|k}(\mathbb{G}_m) \times \mathbb{G}_m \) and is therefore not special, as it can be seen directly or from the classification of special tori recalled in Theorem 5.1 below.

### 4 Classification results

We start by classifying special reductive groups over the field \( k \) in Theorem 4.1 below. This classification is obtained as a straightforward consequence of the results from Sections 2 and 3. However, conditions (1) and (2) in Theorem 4.1 are very explicit, unlike condition (3). Under the additional assumption that the group \( G \) is semisimple, reductive of inner type or quasisplit, we will make condition (3) explicit as well, providing an explicit classification in these cases.

**Theorem 4.1.** Let \( G \) be a reductive algebraic group over \( k \). Then \( G \) is special if and only if the following three conditions hold:

1. The derived subgroup of \( G \) is isomorphic to

\[
R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)
\]

where, for each \( i \), the extension \( K_i \) of \( k \) is finite and separable and the group \( G_i \) is isomorphic over \( K_i \) to either \( SL_1(A_i) \), where \( A_i \) is a central simple algebra over \( K_i \), or \( Sp_{2n_i} \) for some integer \( n_i \).

2. The coradical \( C_G \) of \( G \) is a special torus.
(3) For every field extension $K$ of $k$, we have

$$\text{Im}(\alpha_{G',K}) + \text{Ker}(H^1(K, Z_{G'}) \rightarrow H^1(K, Z_G)) = H^1(K, Z_{G'}).$$

**Proof.** If $G$ is special, then (1) is satisfied by Proposition 3.2, (2) by Proposition 3.4 and (3) by Proposition 2.4. Suppose now that $G$ satisfies the three conditions. By (1) it is easily seen that for every field extension $K$ of $k$, the map $\beta_{G',K}$ has trivial kernel. Together with (2) and (3), it implies that $G$ is special, by Proposition 2.4. □

### 4.1 The classification of special semisimple groups

We provide now the classification of special semisimple groups over the field $k$.

**Proposition 4.2.** Let $G$ be a semisimple algebraic group over $k$. Then $G$ is special if and only if it is isomorphic to

$$R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$

where, for each $i$, the extension $K_i$ of $k$ is finite and separable and the group $G_i$ is isomorphic over $K_i$ to $\text{SL}_{n_i}$ or $\text{Sp}_{2n_i}$ for some integer $n_i$.

**Proof.** The “if part” of the proposition follows directly from Schapiro’s lemma and the fact that the split groups $\text{SL}_{n}$ and $\text{Sp}_{2n}$ are special for every integer $n$. For the “only if part”, we use Proposition 3.2. As $G$ is its own derived subgroup, we find that $G$ is isomorphic to

$$R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)$$

where, for each $i$, the extension $K_i$ of $k$ is finite and separable and the group $G_i$ is isomorphic over $K_i$ to either $\text{SL}_{n_i}$ or $\text{Sp}_{2n_i}$, for some integer $n_i$. Now, for every index $i$, $G_i$ is a direct factor of $G_{K_i}$, and, as such, is a special group. If $G_i$ is isomorphic over $K_i$ to $\text{SL}_{n_i}$ then Lemma 4.3 below shows that $A_i$ is split, completing the proof of the proposition.

**Lemma 4.3.** Let $A$ be a central simple algebra over the field $k$. If $\text{SL}_{n}(A)$ is a special group, then $A$ is split.

This result is part of the folklore, see for example [4, Chapter 2, Exercise 6]. We sketch a proof for the convenience of the reader. Let $k((t))$ be the field of formal Laurent series. By [6, Corollary 29.4] we know that the set $H^1(k((t)), \text{SL}_{n}(A))$ is naturally identified with the cokernel of the reduced norm :

$$\text{Nrd} : (k((t)) \otimes_k A)^* \longrightarrow k((t))^*$$

We claim that the class $[t]$ of $t$ in $H^1(k((t)), \text{SL}_{n}(A))$ is not trivial if $A$ is not split, proving that $\text{SL}_{n}(A)$ is not special in that case.
To see this, we will prove below that the image of the composite:

\[ v \circ \mathrm{Nrd} : (k((t)) \otimes_k A)^* \rightarrow k((t))^* \rightarrow \mathbb{Z} \]

where \( v \) is the valuation given by \( t \), is the ideal spanned by the index \( \text{ind}(A) \) of \( A \).

Let us first show how it implies the result. If \( A \) is not split, then the index of \( A \) is not 1, and we see that \( t \), whose valuation is 1, is not in the image of \( \mathrm{Nrd} \), proving that the class \([t]\) in \( H^1(k((t)), \text{SL}_1(A)) \) is not trivial.

We now prove the result above. Let \( D \) be the division algebra over \( k \) which is Brauer equivalent to \( A \). Observe that the valuation \( v \) extends to \( k((t)) \otimes_k D \), the valuation of

\[ d_r t^r + d_{r+1} t^{r+1} + \cdots \]

being \( r \) if \( d_r \) is not zero. This implies actually that the \( k((t)) \)-algebra \( k((t)) \otimes_k D \) is a division algebra, and is thus the division algebra Brauer-equivalent to \( k((t)) \otimes_k A \).

By [4, Corollary 2.8.10], the image in \( k((t))^* \) of the reduced norms from \( (k((t)) \otimes_k A)^* \) and \( (k((t)) \otimes_k D)^* \) are the same. Therefore, in order to prove the result above, we can replace \( A \) by \( D \). By extending the scalars to \( k_s((t)) \) - which is contained in a separable closure of \( k((t)) \) - where the reduced norm becomes the determinant, we see that the valuation of the reduced norm of

\[ d_r t^r + d_{r+1} t^{r+1} + \cdots \]

where \( d_r \) is not zero, is \( r \dim_k D \), which is equal to \( r \text{ind}(A) \). This completes the proof of the result above.

\[ \square \]

4.2 The classification of special reductive groups of inner type

The split form of a reductive algebraic group \( G \) defined over \( k \) is the unique Chevalley group \( G_{\text{split}} \) over \( k \) which is isomorphic to \( G \) over the algebraic closure \( \bar{k} \) of \( k \). The existence and uniqueness of the split form is guaranteed by Chevalley’s classification of split reductive groups, see for instance [15], and the fact that every reductive group is split over an algebraically closed field.

A reductive algebraic group \( G \) is called of inner type if it is an inner form of its split form, that is, if it is obtained by twisting \( G_{\text{split}} \) by a cocycle with values in the group of inner automorphisms of \( G_{\text{split}} \), see for instance [6, §31]. If \( G \) is a reductive group of inner type, then:

\[ Z_G = Z_{G_{\text{split}}}, \quad Z_G^r = Z_{(G_{\text{split}})^r} \quad \text{and} \quad R_G = R_{G_{\text{split}}}. \]

Consequently, we see that \( Z_G \) and \( Z_G^r \) are split diagonalizable groups and \( R_G \) is a split torus. We provide now the classification of special reductive algebraic groups which are of inner type.
Proposition 4.4. Let $G$ be a reductive algebraic group over $k$ of inner type. The intersection $R'_G$ of $R_G$ with $Z_{G'}$ is a finite split diagonalizable group. We fix an isomorphism:

$$R'_G \cong \mu_{m_1} \times \cdots \times \mu_{m_q}$$

for some integers $m_j$. Then $G$ is special if and only if the following two conditions are satisfied:

1. The derived subgroup $G'$ of $G$ is isomorphic to a direct product:

$$G_1 \times \cdots \times G_s \times \cdots \times G_r \quad (\ast)$$

where, for each index $i$ from 1 to $s$, the group $G_i$ is equal to $\text{SL}_1(A_i)$, with $A_i$ a nonsplit central simple algebra of degree $n_i$ and index $d_i$ over $k$, and, for $i$ from $s+1$ to $r$, the group $G_i$ is equal to either $\text{SL}_{n_i}$ or $\text{Sp}_{2n_i}$ for some integer $n_i$.

2. The projection onto the first $s$ factors in the direct product decomposition $(\ast)$ leads to a morphism:

$$R'_G \cong \mu_{m_1} \times \cdots \times \mu_{m_q} \to Z_{G_1 \times \cdots \times G_s} = \mu_{n_1} \times \cdots \times \mu_{n_s}$$

for some integers $n_i,j$. We set $b_{i,j} = \frac{a_{i,j}m_i}{m_j}$. Then the rows of the following matrix:

$$\begin{bmatrix}
  d_1 & 0 & \ldots & 0 & b_{1,1} & \ldots & b_{1,q} \\
  0 & d_2 & \ldots & 0 & b_{2,1} & \ldots & b_{2,q} \\
  \vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
  0 & 0 & \ldots & d_s & b_{s,1} & \ldots & b_{s,q}
\end{bmatrix}$$

span a saturated sublattice of $\mathbb{Z}^{s+q}$.

Proof. First we prove that if $G$ is special then it satisfies (1). As $G$ is of inner type, it is obtained by twisting the split form $G_{\text{split}}$ of $G$ by a cocycle whose class is in $H^1(k, (G_{\text{split}})_{ad})$. As the last set is equal to $H^1(k, (G'_{\text{split}})_{ad})$, and the group $G'_{\text{split}}$ is a direct product of absolutely simple simply connected groups - because it is the derived subgroup of the special split reductive group $G_{\text{split}}$ - we see that $G'$, which is obtained from $G'_{\text{split}}$ by the same twisting procedure, is a direct product of absolutely simple simply connected groups of type A and C. By Proposition 3.2, the factors are either of inner type A or split of type C, proving that $G$ satisfies (1).

We suppose now that $G$ satisfies (1), and we claim that $G$ is special if and only if it satisfies (2). It is readily seen that $G$ satisfies the first assertion of Theorem 4.1 and also the second, as the coradical of $G$ is a split torus - it is the coradical of the split form $G_{\text{split}}$ of $G$. Therefore to prove the claim, it suffices to show that (2) is satisfied if and only if the third assertion of Theorem 4.1 is satisfied. In order to do this, we first identify the kernel of the following morphism :

$$H^1(K, Z_{G'}) \to H^1(K, Z_G).$$
There is an isomorphism from the group $Z_G$ to $R_G \times (Z_{G'}/R'_G)$ such that the projection of the subgroup $Z_{G'}$ on the second factor is the natural projection from $Z_{G'}$ onto $Z_G/R_G$. This follows from the fact that the inclusion of $G'$ into $G$ provides an isomorphism from $G'/R_G$ to $G/R_G$, and therefore an isomorphism from the center $Z_{G'}/R'_G$ of the first group to the center $Z_G/R_G$ of the second group, together with the fact that $Z_G$ is a split diagonalizable group and $R_G$ is a split torus, implying that the exact sequence

$$1 \rightarrow R_G \rightarrow Z_G \rightarrow Z_G/R_G \rightarrow 1$$

splits. Let $K$ be a field extension of $k$. By using the isomorphism above and Hilbert’s theorem 90 the set $H^1(K, Z_G)$ is identified with $H^1(K, Z_{G'}/R_G)$ and the morphism from $H^1(K, Z_{G'})$ to $H^1(K, Z_G)$ induced by the inclusion with the morphism:

$$H^1(K, Z_{G'}) \rightarrow H^1(K, Z_{G'}/R'_G)$$

given by the projection from $Z_{G'}$ to $Z_{G'}/R'_G$. This proves the following equality

$$\text{Ker}(H^1(K, Z_{G'}) \rightarrow H^1(K, Z_G)) = \text{Im}(H^1(K, R'_G) \rightarrow H^1(K, Z_{G'})).$$

Observe now that the map $\alpha_{G',K}$ is the direct product of the maps $\alpha_{G_i,K}$, where $i$ ranges from 1 to $r$. As the group $G_i$ is special for $i$ between $s+1$ and $r$ we know by Proposition 2.2 that $\alpha_{G_i,K}$ is surjective. As a consequence, the third assertion in Theorem 4.1 is satisfied by the group $G$ if and only if

$$\text{Im}(\alpha_{G_1 \times \cdots \times G_s,K}) + \text{Im}(H^1(K, R'_G) \rightarrow H^1(K, Z_{G_1 \times \cdots \times G_s})) = H^1(K, Z_{G_1 \times \cdots \times G_s})$$

where the morphism

$$H^1(K, R'_G) \rightarrow H^1(K, Z_{G_1 \times \cdots \times G_s})$$

is induced by the composite $\varphi$ of the inclusion of $R'_G$ in $Z_{G'}$ followed by the projection on $Z_{G_1 \times \cdots \times G_s}$. The morphism $\varphi$ has the following explicit description:

$$\varphi : \mu_{m_1} \times \cdots \times \mu_{m_q} \rightarrow \mu_{n_1} \times \cdots \times \mu_{n_r},$$

$$(x_1, \ldots, x_q) \mapsto (x_1^{a_1,1} \cdots x_q^{a_1,q}, \ldots, x_1^{a_r,1} \cdots x_q^{a_r,q})$$

Its corresponding morphism in fppf cohomology is given by:

$$K^*/(K^*)^{(m_1)} \times \cdots \times K^*/(K^*)^{(m_q)} \rightarrow K^*/(K^*)^{(n_1)} \times \cdots \times K^*/(K^*)^{(n_r)}$$

$$([x_1], \ldots, [x_q]) \mapsto ([x_1^{b_1,1} \cdots x_q^{b_1,q}], \ldots, [x_1^{b_r,1} \cdots x_q^{b_r,q}])$$

where $b_{i,j} = \frac{a_{i,j} m_i}{m_j}$, and $(K^*)^{(n)}$ denotes the group of $n$th power of elements of $K^*$. Furthermore, for each index $i$ from 1 to $s$, the map $\alpha_{G_i,K}$:

$$\text{PSL}_4(A_i(K)) = (A_i)^*/K^* \rightarrow H^1(K, \mu_{n_i}) = K^*/(K^*)^{(n_i)}$$

maps the class of an element $g$ of $(A_i)^*_{K'}$ to the class of its reduced norm. Therefore, Lemma 4.5 below completes the proof of the proposition.
Lemma 4.5. The following conditions are equivalent:

(1) the rows of the following matrix:

\[
\begin{bmatrix}
d_1 & 0 & \ldots & 0 & b_{1,1} & \ldots & b_{1,q} \\
0 & d_2 & \ldots & 0 & b_{2,1} & \ldots & b_{2,q} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \ldots & d_s & b_{s,1} & \ldots & b_{s,q}
\end{bmatrix}
\]

span a saturated sublattice of \(\mathbb{Z}^{s+q}\).

(2) for every field extension \(K\) of \(k\), the map:

\[
\gamma_K : \prod_{i=1}^{s} \text{Nrd}((A_i)_K^*) \times (K^*)^q \to (K^*)^r
\]

\(\left( y_1, \ldots, y_s, x_1, \ldots, x_q \right) \mapsto \left( x_1^{b_{1,1}} \cdots x_q^{b_{1,q}} y_1, \ldots, x_1^{b_{s,1}} \cdots x_q^{b_{s,q}} y_s \right)\)

is surjective.

Proof of Lemma 4.5. Suppose that (1) hold. Let \(M\) be the matrix in (1). First, as the rows of \(M\) are linearly independent, the morphism of algebraic tori:

\[
\mathbb{G}_m^{q+s} \to \mathbb{G}_m^s
\]

\(\left( y_1, \ldots, y_s, x_1, \ldots, x_q \right) \mapsto \left( x_1^{b_{1,1}} \cdots x_q^{b_{1,q}} y_1, \ldots, x_1^{b_{s,1}} \cdots x_q^{b_{s,q}} y_s \right)\)

is surjective. Its kernel is precisely the subtorus of \(\mathbb{G}_m^{q+s}\) whose character lattice is the quotient of \(\mathbb{Z}^{s+q}\) by the rows of \(M\). By assumption this kernel is therefore a split torus. By Hilbert’s theorem 90, for every field extension \(K\) of \(k\), the map:

\(\left( K^* \right)^{s+q} \to \left( K^* \right)^s\)

\(\left( y_1, \ldots, y_s, x_1, \ldots, x_q \right) \mapsto \left( x_1^{b_{1,1}} \cdots x_q^{b_{1,q}} y_1, \ldots, x_1^{b_{s,1}} \cdots x_q^{b_{s,q}} y_s \right)\)

induced on the \(K\)-points is surjective. As for each index \(i\) between 1 and \(s\) the subgroup \(\text{Nrd}((A_i)_K^*)\) of \(K^*\) contains \((K^*)^{(d_i)}\), we see that the map \(\gamma_K\) is surjective.

Suppose now that (1) fails. There exists a primitive element \((c_1, \ldots, c_s)\) of \(\mathbb{Z}^s\) such that the element

\[
\sum_{i=1}^{s} c_i(0, \ldots, d_i, \ldots, 0, b_{i,1}, \ldots, b_{i,q})
\]

is divisible, say by \(d\), in \(\mathbb{Z}^{s+q}\). Let \(K\) be the field of Laurent series \(k((t))\) and \(v\) the valuation defined by \(t\). As the element \((c_1, \ldots, c_s)\) is primitive, the map

\(\left( K^* \right)^s \to K^*\)

\((z_1, \ldots, z_s) \mapsto z_1^{c_1} \cdots z_s^{c_s}\)
is surjective. We claim now that if \((z_1, \ldots, z_s)\) belongs to the image of \(\gamma_K\) then the valuation of \(z_1^{c_1} \cdots z_s^{c_s}\) is divisible by \(d\), proving that \(\gamma_K\) is not surjective.

To prove the claim, let:

\[(y_1, \ldots, y_s, x_1, \ldots, x_q) \in \prod_{i=1}^s \text{Nrd}((A_i)_K^*) \times (K^*)^q,
\]

and

\[(z_1, \ldots, z_s) = \gamma_K(y_1, \ldots, y_s, x_1, \ldots, x_q).
\]

We have:

\[z_1^{c_1} \cdots z_s^{c_s} = y_1^{c_1} \cdots y_s^{c_s} x_1^{\sum_{i=1}^s c_i b_{i,1}} \cdots x_q^{\sum_{i=1}^s c_i b_{i,q}}.
\]

For every \(i\) from 1 to \(s\) the integer \(v(y_i)\) is divisible by \(d_i\), as \(y_i\) is a reduced norm of the central simple algebra \((A_i)_K\) over \(K\) and the index of \(A_i\) over \(k\) is \(d_i\). Therefore \(v(y_i^{c_i})\) is divisible by \(c_i d_i\), hence by \(d\). Moreover, for every index \(j\) between 1 and \(q\), the sum \(\sum_{i=1}^s c_i b_{i,j}\) is also divisible by \(d\), completing the proof of the claim.

Here is an example of a situation where condition (2) in Proposition 4.4 is easy to work out. Suppose that the group \(R'_G\) decomposes along the direct factor decomposition (*) in (1). That is,

\[R'_G \simeq \mu_{m_1} \times \cdots \times \mu_{m_r},
\]

where, for each index \(i\), \(\mu_{m_i}\) is a subgroup of \(Z_{G_i}\). In this setting, condition (2) in Proposition 4.4 is equivalent to the fact that for every \(i\) from 1 to \(s\) the integers \(d_i\) and \(n_i\) are relatively prime.

4.3 The classification of special quasisplit groups

Recall that a reductive group \(G\) over a field \(k\) is called quasisplit if it possesses a Borel subgroup defined over \(k\), see for instance [13, III, 2.2], or, in other words, if the variety of Borel subgroups of \(G\) has a rational point. We show now that a quasisplit group is special if and only if its derived subgroup and coradical are special.

**Proposition 4.6.** Let \(G\) be a reductive algebraic group over \(k\). Then \(G\) is quasisplit and special if and only if there exists an exact sequence of algebraic groups:

\[1 \longrightarrow D \longrightarrow G \longrightarrow C \longrightarrow 1
\]

where \(D\) is isomorphic to a direct product:

\[R_{K_1|k}(G_1) \times R_{K_2|k}(G_2) \times \cdots \times R_{K_r|k}(G_r)
\]

where, for every index \(i\), \(K_i\) is a finite separable extension of \(k\), \(G_i\) is equal to either \(\text{SL}_{n_i}\) or \(\text{Sp}_{2n_i}\), for some integer \(n_i\), and the group \(C\) is a special torus over \(k\). In that case, \(D\) is the derived subgroup of \(G\) and \(C\) is the coradical of \(G\).
Proof. If such an exact sequence exists, then, as \( D \) and \( C \) are special, it follows readily from the derived exact sequence of pointed sets in fppf-cohomology that \( G \) is special as well. Moreover, as \( C \) is commutative, the derived subgroup \( G' \) is contained in \( D \). Now, as \( D \) is semisimple, it is equal to its own derived subgroup, and is in particular contained in \( G' \). Finally, we see that \( D \) is equal to \( G' \), and the fact that \( C \) is the coradical of \( G \) follows readily. Now, as \( G \) and \( G' \) share the same variety of Borel subgroups, and \( G' \) is quasisplit, we see that \( G \) is quasisplit as well.

Suppose now that \( G \) is quasisplit and special. By the same argument as above, the derived subgroup \( G' \) is quasisplit. Moreover, by Proposition 3.2, \( G'' \) is isomorphic to

\[
R_{K_i|k}(G_1) \times R_{K_i|k}(G_2) \times \cdots \times R_{K_i|k}(G_r)
\]

where, for each index \( i \), the extension \( K_i \) of \( k \) is finite and separable and the group \( G_i \) is isomorphic over \( K_i \) to either \( \text{SL}_1(A_i) \), where \( A_i \) is a central simple algebra over \( K_i \), or \( \text{Sp}_{2n_i} \) for some integer \( n_i \). For each index \( i \) such that \( G_i \) is isomorphic to \( \text{SL}_1(A_i) \), we see that \( \text{SL}_1(A_i) \) is a direct factor of \( G_{K_i} \). As \( G_{K_i} \) is quasisplit, this forces \( \text{SL}_1(A_i) \) to be quasisplit as well, implying that \( A_i \) is split. By Proposition 3.4, the coradical of \( G \) is special. We thus have an exact sequence as in the proposition, with \( D \) the derived subgroup \( G' \) of \( G \) and \( C \) the coradical \( C_G \).

Let \( G \) be an arbitrary reductive group over the field \( k \). There is a unique inner form of \( G \) that is quasisplit, called the quasisplit form \( G_{qsplit} \) of \( G \), see for instance [15]. In the following proposition, we prove that the quasisplit form of \( G \) is special if \( G \) is special. This is very reasonable, as we expect \( G_{qsplit} \) to be less “twisted” than \( G \).

**Proposition 4.7.** Let \( G \) be a special reductive group over \( k \). The quasisplit form of \( G \) is special as well.

**Proof.** The groups \( G \) and \( G_{qsplit} \) share the same coradical, and \( (G_{qsplit})' \) is the quasisplit form of \( G' \). Therefore, by Proposition 3.2 and 3.4, the derived subgroup and coradical of \( G_{qsplit} \) are special, proving that \( G_{qsplit} \) is special.

5 Special tori

In this section we give the classification of special tori after Colliot-Thélène. This classification is implicitly contained in [3] and explicitly given in the first version of [1] on the ArXiv but not in the published version. For this reason we thought that it would be a good idea to include it in the present paper. We actually reproduce the proof from [1]. The relevance of the classification of special tori for our problem of classifying reductive groups is twofold: firstly, tori are reductive groups and secondly, by Proposition 3.4, the coradical of a special reductive group is a special torus.

Let \( k \) be a base field, \( k_s \) a fixed separable closure and \( \Gamma \) the absolute Galois group \( \text{Gal}(k_s|k) \) of \( k \). A continuous \( \Gamma \)-module is called a permutation \( \Gamma \)-module.
if it is a free $\mathbb{Z}$-module possessing a basis which is permuted by the action of $\Gamma$. A continuous $\Gamma$-module is called invertible if it is a direct factor of a permutation $\Gamma$-module.

**Theorem 5.1** (Colliot-Thélène). Let $T$ be a torus defined over a field $k$. The torus $T$ is special if and only if the character lattice of $T_{k_s}$ is invertible.

**Proof.** If the character lattice of $T_{k_s}$ is invertible, then $T$ is a direct factor of a finite product of tori of type $R_{K|k}(\mathbb{G}_{m,K})$, where $K$ is a finite separable extension of $k$ and $\mathbb{G}_{m,K}$ is the multiplicative group over $K$. By Hilbert’s theorem 90 and Schapiro’s lemma, it follows that $T$ is special.

Conversely, assume that $T$ is special. Let $K$ be a finite separable field extension of $k$. By Lemma 5.2 below, $H^1(\mathbb{G}_{m,K}, N) = 0$ where $N$ is the cocharacter lattice of $T_{k_s}$. Since the torus $T$ is special, we see that $H^1(k, N) = 0$. As this property holds for every finite separable field extension $K$ of $k$, it means that the torus $T$ is flasque. By [3, Proposition 7.4] a flasque torus is special if and only if the character lattice of $T_{k_s}$ is invertible, which completes the proof, modulo the following lemma:

**Lemma 5.2.** For any torus over the field $k$, there is an isomorphism :

$$H^1(k((t)), T) \simeq H^1(k, T) \oplus H^1(k, N)$$

where $N$ is the cocharacter lattice of $T_{k_s}$.

**Proof of Lemma 5.2.** Set $K(k((t)))$. Let $L$ be the union of the field $k'((t))$ for all finite extensions of $k$ inside $k_s$. Then the Galois group $\text{Gal}(L/K)$ is equal to $\Gamma$. We have the inflation-restriction exact sequence, see for example [13, I.2.6(b)]:

$$1 \rightarrow H^1(\Gamma, T(L)) \rightarrow H^1(K, T) \rightarrow H^1(L, T) \rightarrow 1$$

The torus $T$ is split over $L$, hence, by Hilbert’s theorem 90, we see that the sets $H^1(\Gamma, T(L))$ and $H^1(K, T)$ are equal. By [2, Lemma 5.17(3)], we have

$$H^1(\Gamma, T(L)) \simeq H^1(\Gamma, T(k_s[t, t^{-1}]))$$

Now, we write :

$$T(k_s[t, t^{-1}]) = N \otimes_{\mathbb{Z}} k_s[t, t^{-1}]^* = N \otimes_{\mathbb{Z}} (k_s^* \oplus \mathbb{Z}) = T(k_s) \oplus N$$

because $T$ splits over $k_s$ and $k_s[t, t^{-1}]^*$ is equal to $k_s^* \oplus \mathbb{Z}$. Finally, we obtain :

$$H^1(K, T) \simeq H^1(\Gamma, T(L)) \simeq H^1(\Gamma, T(k_s[t, t^{-1}])) \simeq$$

$$H^1(\Gamma, T(k_s)) \oplus H^1(\Gamma, \oplus N) \simeq H^1(k, T) \oplus H^1(k, \oplus N).$$
