The lepton flavor violating decay of the Higgs boson \( H \rightarrow l_A l_B \) is studied within two qualitatively different extensions of the Yukawa sector: one renormalizable and the other nonrenormalizable; both incorporating Lorentz violation in a model-independent fashion. These extensions are characterized by Yukawa-like matrices, the former by the constant Lorentz 2-tensor \( Y_{\mu AB} \), whereas the latter by the constant Lorentz vector \( Y_{\mu}^{AB} \). It is found that the experimental constraints on the decays \( l_A \rightarrow l_B \gamma \) severely restrict lepton flavor violating Higgs signals in the renormalizable scenario, as the electromagnetic transitions arise at tree level. In this context, it is found that the branching ratios of the decays \( H \rightarrow \mu^+e^- \) and \( H \rightarrow \tau^+\mu^- \) can not be larger than \( 10^{-18} \) and \( 10^{-11} \), respectively. In the nonrenormalizable scenario, the electromagnetic transitions arise at one-loop level and transitions mediated by the Higgs or the Z gauge boson are induced at tree level, hence we find mild restrictions on lepton flavor violation. Using the experimental limits on the three-body decays \( l_A \rightarrow l_B l_C \gamma \) to constraint the vector \( Y_{\mu}^{AB} \), it is found that the branching ratio for the decays \( H \rightarrow \mu^+e^- \) is of about \( 4 \times 10^{-19} \), more important, a branching ratio of \( 7 \times 10^{-4} \) is found for the \( \tau^+\mu^- \) mode. Accordingly, the decay \( H \rightarrow \tau^+\mu^- \) could be at the reach of future measurements. The lepton flavor violating decays of the Z gauge boson were also studied. In the renormalizable scenario, it was found the undetectable branching ratios \( BR(Z \rightarrow \mu^+e^-) < 5.7 \times 10^{-21} \) and \( BR(Z \rightarrow \tau^+\mu^-) < 2.0 \times 10^{-12} \). As far as the nonrenormalizable scenario is concerned, it was found that \( BR(Z \rightarrow \mu^+e^-) < 0.67 \times 10^{-12} \) and \( BR(Z \rightarrow \tau^+\mu^-) < 1.12 \times 10^{-11} \). Although the latter branching ratio is relatively large, it still could not be within the range of future measurements.

I. INTRODUCTION

The flavor or property that distinguishes different members in the two groups of basic building blocks of matter, the quarks and the leptons, is a feature of the Standard Model (SM) whose real origin still needs more exploration. There are many open questions about the flavor. In the SM, the recently discovered Higgs boson \[1\] is responsible for the masses of all known elementary particles. This field endows with different masses to quarks and leptons through the Higgs mechanism, one of the most successful predictions of the SM. However, as far as the nonrenormalizable scenario is concerned, it was found that the branching ratios of \( \tau \rightarrow \mu \gamma \) could not be within the range of future measurements.

As far as the Z gauge boson is concerned, the allowed LFV decays are less restricted by the experiment; the most recent bounds are given by \[2\]

\[
BR_{\exp}(Z \rightarrow \mu^+\mu^-) < 1.7 \times 10^{-6} \quad \text{(I.2a)}
\]
\[
BR_{\exp}(Z \rightarrow e^+\tau^-) < 9.8 \times 10^{-6} \quad \text{(I.2b)}
\]
\[
BR_{\exp}(Z \rightarrow \mu^+\tau^-) < 1.2 \times 10^{-5} \quad \text{(I.2c)}
\]

On the other hand, very stringent bounds arise also from leptonic three-body decays \( l_A \rightarrow l_B l_C \gamma \). The Particle Data

\[\ldots\]
Group reports the following limits:

\[
\begin{align*}
BR_{\exp}(\mu \rightarrow ee^+e^-) &< 1.0 \times 10^{-12}, \\
BR_{\exp}(\tau \rightarrow ee^+e^-) &< 2.7 \times 10^{-8}, \\
BR_{\exp}(\tau \rightarrow \mu e^+e^-) &< 1.8 \times 10^{-8}, \\
BR_{\exp}(\tau \rightarrow \mu\mu^+\mu^-) &< 2.1 \times 10^{-8}.
\end{align*}
\]

(I.3d)

Undoubtedly, the recent discovery of the Higgs boson at the Large Hadron Collider (LHC) opens a new era in high-energy Higgs physics. In order to establish unambiguously that this scalar resonance corresponds to the Higgs boson predicted by the SM, many of the forthcoming experiments in LHC will be focused on studying its decays into SM particles. The properties of this particle will also be under scrutiny at the International Linear Collider (ILC)\(^2\), which is currently at the planning stage. This ambitious program of electron-positron collisions, operating with a center-of-mass energy in the range of 500 – 1000 GeV, will provide a clean environment to make studies beyond the capabilities of the LHC, expanding our knowledge of the SM by opening access to new physics that could eventually be unfolded through quantum fluctuations of SM observables. Effects of new heavy particles would show up more clearly in those processes that are forbidden or very suppressed in the SM. In this category are the LFV decays of the Higgs boson into pairs of distinct charged leptons, \(H \rightarrow l_A l_B\), as they are forbidden in the SM. Although strictly forbidden in the SM, Higgs-mediated decays involving LFV arise naturally in the presence of extended Higgs sectors. This phenomenon has been the subject of important interest in the literature within the context of the two-Higgs doublet model\(^4\), supersymmetric theories\(^5\), unparticle models\(^6\), 331 models\(^7\), seesaw models with Majorana massless neutrinos\(^8\), and in model-independent way using the effective Lagrangian technique\(^9\)\(^10\).

The purpose of this work is to study the LFV Higgs boson \(H \rightarrow l_A l_B\) decays within the context of the Standard Model Extension (SME)\(^11\), which is a SM extension that incorporates in a model-independent fashion both \(CPT\) and Lorentz violation. Although motivated from specific scenarios in the context of strings theory\(^12\), general relativity with spontaneous symmetry breaking\(^13\) or field theories formulated in a noncommutative space-time\(^14\)\(^–\)\(^17\), the SME is beyond these specific ideas due to its generality, which is the main advantage of effective field theories. Thus the SME provides us with a powerful tool for investigating \(CPT\) nonconservation and Lorentz violation in a model-independent manner. Although these effective theories introduce constant background fields that carry Lorentz indices, they are not Lorentz invariants under general Lorentz transformations, but only under observer Lorentz transformations\(^18\). In general, the SME is made of pieces of the form \(T^{\mu_1 \cdots \mu_n} \mathcal{O}_{\mu_1 \cdots \mu_n} (x)\), where the \(\mathcal{O}_{\mu_1 \cdots \mu_n} (x)\) Lorentz \(n\)-tensors depend on the SM fields and are invariant under the SM gauge group, whereas the constant \(T^{\mu_1 \cdots \mu_n}\) quantities transform as Lorentz \(n\)-tensors under observer Lorentz transformations, but do not under the so-called particle Lorentz transformations\(^18\). The SME action can contain some \(CPT\)-odd terms, which necessarily implies Lorentz violation\(^19\). Although the minimal version of the SME\(^11\) is constructed by adding to the SM Lagrangian new observer Lorentz invariant objects of the form described above, which are renormalizable in the Dyson’s sense, it can be enlarged to include nonrenormalizable interactions\(^20\). In this work, we will focus on a Yukawa sector extended by both renormalizable and nonrenormalizable Lorentz violating interactions, which directly induces the \(HL_A l_B\) vertex at tree level. We will show that Higgs-mediated LFV is quite suppressed in the context of the renormalizable version of the SME due to experimental constraints, but it can reach significant branching ratios in the context of its nonrenormalizable enlargement.

The rest of the paper has been organized as follows. In Sec.II the phenomenon of LFV mediated by the photon, the \(Z\) gauge boson, and the Higgs boson is studied in the context of the Yukawa sector of the renormalizable version of the SME. In this context, the experimental constraints on the photon-mediated transitions \(l_A \rightarrow l_B \gamma\) are implemented to predict the LFV decays \(H \rightarrow l_A l_B\) and \(Z \rightarrow l_A l_B\). Sec.III is devoted to investigate the possible gauge and Lorentz observer invariant Yukawa-like operators of the lowest nonrenormalizable dimension that can generate Higgs-mediated LFV. In this enlarged version of the SME, the experimental constraints on the LFV three-body decays \(l_A \rightarrow l_B l_C\) are employed to predict the branching ratios of the \(H \rightarrow l_A l_B\) and \(Z \rightarrow l_A l_B\) decays. Finally, in Sec.IV the conclusions are presented.

II. LORENTZ VIOLATING YUKAWA SECTOR: RENORMALIZABLE EXTENSION

In this section, we focus on the renormalizable extension to the leptonic Yukawa sector that induces LFV mediated by the Higgs boson. The only renormalizable extension of this sector is given by\(^11\)

\[
\mathcal{L}_{Y}^{CPT-\text{even}} = -\frac{1}{2} Y_{\mu \nu}^{AB} l_A ^{\dagger} \Phi \sigma^{\mu \nu} R_B ^{\dagger} + \text{h.c.},
\]  

(II.1)
where $\Phi$ is the $SU_L(2)$ Higgs doublet, whereas $L'$ and $R'$ are left–handed and right–handed lepton doublet and singlet of $SU_L(2)$, respectively. The dimensionless matrix $Y'$ is antisymmetric in the Lorentz indices but symmetric, although not necessarily Hermitian, in the flavor space. In the unitary gauge, the above Lagrangian can be written as follows:

$$\mathcal{L}^{CPT-even}_Y = -\frac{1}{2\sqrt{2}}(v + H) \bar{E}'_L Y'_\mu \nu \sigma^{\mu\nu} E'_R + \text{h.c.}, \quad (\text{II.2})$$

where $E' = (e', \mu', \tau')$ is a vector in the flavor space. We now perform the change of basis from $(E'_L, E'_R)$ to the mass-eigenstate basis $(E_L, E_R)$ via the unitary transformation

$$E'_L = V^L_L E_L, \quad E'_R = V^R_R E_R, \quad (\text{II.3a})$$

$$E''_L = V^L_L V^R_R E', \quad E''_R = \alpha \delta_{LR} + \beta \delta_{LR}, \quad (\text{II.3b})$$

which, as is well known, simultaneously diagonalizes the mass term and the Higgs-lepton interactions in the SM, but in this case introduces non-diagonal effects in the Lorentz violating extension,

$$\mathcal{L}^{CPT-even}_Y = -\frac{1}{2}(v + H) \bar{E}_L Y_{\mu\nu} \sigma^{\mu\nu} E_L, \quad (\text{II.4})$$

where $Y_{\mu\nu} = V^L_L Y_{\mu\nu} V^R_R$. Although the case of the most general $Y$ matrix may have interesting implications in some processes, such as the induction of CP violation, for our purposes it is sufficient to assume it real and symmetric. Henceforth,

$$\mathcal{L}^{CPT-even}_Y = -\frac{1}{2}(v + H) \bar{E}_{\mu\nu} Y_{\mu\nu} E_L, \quad (\text{II.5})$$

leads to a bilinear coupling $l_A l_B$, with vertex $-\frac{i}{2} Y_{\mu\nu} \sigma^{\mu\nu}$, and contains a LFV coupling of the Higgs boson $H l_A l_B$, whose vertex function is given by $-\frac{i}{2} Y_{\mu\nu} \sigma^{\mu\nu}$.

A. The decay $H \rightarrow l_A^{\pm} l_B^{\mp}$

The decay $H \rightarrow l_B l_A + l_A l_B$ occurs via the Feynman diagrams shown in Fig[I]. Both the bilinear $l_A l_B$ and trilinear $H l_A l_B$ couplings contribute to this process at tree level. The invariant amplitude for the decay $H \rightarrow l_B l_A$ can be written as follows:

$$\mathcal{M}(H \rightarrow l_B l_A) = -\frac{i}{2} Y_{\alpha\beta}^{AB} \bar{v}(p_2, s_2) \left( \sigma^{\alpha\beta} + \frac{m_B}{m_A - m_B} \left( q_1 + m_B \right) \sigma^{\alpha\beta} - \frac{m_A}{m_A - m_B} \sigma^{\alpha\beta} \left( q_2 + m_A \right) \right) u(p_1, s_1). \quad (\text{II.6})$$

Notice that the contribution of the $H l_A l_B$ vertex (first diagram in Fig[I]) is exactly cancelled by the contributions of the bilinear coupling $l_A l_B$. Once this amplitude is squared, the following branching ratio for the decay $H \rightarrow l_A^{\pm} l_B^{\mp}$ is obtained:

$$BR(H \rightarrow l_A^{\pm} l_B^{\mp}) = \frac{1}{4\pi} \left( \frac{m_H}{\Gamma_H} \right) \frac{m_H^4}{(m_A^2 - m_B^2)^2} \left| f(m_H, m_A, m_B) \right|^2 \left| Y_{\alpha\beta}^{AB} Y_{\beta\rho}^{AB} T^{\alpha\rho} \right|^2, \quad (\text{II.7})$$

where

$$f(m_H, m_A, m_B) = \left[ 1 - \left( \frac{m_A + m_B}{m_H} \right) \right]^{5/2} \left[ 1 - \left( \frac{m_A - m_B}{m_H} \right)^2 \right]^{1/2}, \quad (\text{II.8})$$

and $T^{\alpha\beta\lambda\rho}$ is given by

$$T^{\alpha\beta\lambda\rho} = \frac{m_B^2}{m_H^2 - (m_A + m_B)^2} \left( g^{\alpha\lambda} g^{\beta\rho} - g^{\alpha\rho} g^{\beta\lambda} \right) + \frac{m_B}{m_A} \left( A^{\alpha\beta\lambda\rho} + \frac{m_H^2 - m_A^2 - m_B^2}{m_H^2 - (m_A + m_B)^2} B^{\alpha\beta\lambda\rho} \right)$$

$$+ \left( \frac{m_B}{m_A} \right)^2 P^{\alpha\beta\lambda\rho}(p_1, p_1) + P^{\alpha\beta\lambda\rho}(p_2, p_2). \quad (\text{II.9})$$
In order to predict this branching ratio, we need to estimate the parameters in

\[ A^{\alpha \beta \lambda \rho} = \left( \frac{p^1_2 p^2_1 - p^1_1 p^2_2}{m_H^2 - (m_A + m_B)^2} \right), \]

(II.10a)

\[ P^{\alpha \beta \lambda \rho} = \frac{(p^1_1 p^2_2 + p^2_1 p^1_2) g^{\alpha \rho} - (p^1_1 p^2_1 + p^2_1 p^1_2) g^{\beta \rho} + (p^1_2 p^2_1 + p^2_2 p^1_1) g^{\beta \lambda} - (p^1_2 p^2_2 + p^2_2 p^1_2) g^{\alpha \lambda}}{m_H^2 - (m_A + m_B)^2}, \]

(II.10b)

and \( P^{\alpha \beta \lambda \rho} \) explicitly reads as follows:

\[ P^{\alpha \beta \lambda \rho}(p_1, p_2) = \frac{p^i_2 p^j_1 g^{i \rho} - p^i_1 p^j_2 g^{i \rho} + p^j_2 p^i_1 g^{j \lambda} - p^j_1 p^i_2 g^{j \lambda}}{m_H^2 - (m_A + m_B)^2}, \]

(II.10c)

Notice that all these tensors are antisymmetric in the pairs of indices \( \alpha \beta \) and \( \lambda \rho \), and symmetric under the interchange \( \alpha \beta \leftrightarrow \lambda \rho \), in agreement with the antisymmetry property of \( Y \) in its Lorentz indices and the structure of (II.7).

In the limit \( m_B \to 0 \) and depreciating \( m_A \) against \( m_H \) whenever possible, the branching ratio reduces to

\[ BR(H \to l^+_{A} l^-_{B}) = \frac{1}{4\pi} \left( \frac{m_H}{m_A} \right)^4 \left| \left( \frac{2p_2}{m_H} \right) \cdot (Y^{AB} Y^{AB}) \cdot \left( \frac{2p_2}{m_H} \right) \right|, \]

(II.11)

where

\[ p \cdot (Y^{AB} Y^{AB}) \cdot q = p^i Y^{\alpha \beta}_{i \bar{\alpha} \bar{\beta}} g_{\beta \lambda} Y^{AB} \lambda \rho q_{\rho}. \]

(II.12)

In this kinematical limit, \( E_1 = E_2 = |p_1| = |p_2| \equiv |p| = m_H/2 \). Taking advantage of the property \( Y^{AB}_{\alpha \beta} = -Y^{AB}_{\bar{\beta} \alpha} \) we define the electric-like vector \( Y^{AB}_{\bar{e}_i} = e_{iAB} \) and the magnetic-like vector \( Y^{AB}_{ij} = \epsilon_{ijk} b^{AB}_k \), just like the relation between the electric and magnetic fields with the corresponding electromagnetic strength tensor. Thus Eq. (II.11) can be rewritten in terms of vectors \( e^{AB} \) and \( b^{AB} \) as follows:

\[ \left\| f_1(\hat{p}, e^{AB}, b^{AB}) \right\| = \left\| \left( \frac{2p_2}{m_H} \right) \cdot (Y^{AB} Y^{AB}) \cdot \left( \frac{2p_2}{m_H} \right) \right\| = \left\| (e^{AB})^2 + (b^{AB})^2 + 2p \cdot (e^{AB} \times b^{AB}) - (\hat{p} \cdot e^{AB})^2 - (\hat{p} \cdot b^{AB})^2 \right\|, \]

(II.13)

where \( \hat{p}_2 \equiv \frac{p_2}{|p_2|}, e^{AB} = |e^{AB}|, \) and \( b^{AB} = |b^{AB}| \). In terms of the electromagnetic-like vectors and the \( \hat{p}_2 \) direction, the Higgs branching ratio is

\[ BR(H \to l^+_{A} l^-_{B}) = \frac{1}{4\pi} \left( \frac{m_H}{m_A} \right)^4 \left| f_1(\hat{p}, e^{AB}, b^{AB}) \right|. \]

(II.14)

In order to predict this branching ratio, we need to estimate the parameters in \( Y^{AB}_{\alpha \beta} \). In the next subsection, we do this using experimental constraints.

**B. The decay \( Z \to l^+_B l^-_B \)**

As the branching ratios (II.11)-(II.13) indicate, the current bounds on the decays \( Z \to l_B l_A + l_A l_B \) are not as severe as those imposed on the electromagnetic transitions, or as those set on the three-body decays of charged leptons. So, there may still be a window to observe LFV mediated by the \( Z \) gauge boson. In this subsection, we study the impact
of the renormalizable extension of the Yukawa sector on these \( Z \) decays. These decays have contributions at tree level due to the bilinear couplings \( l_A l_B \), as it is shown in Fig. 2. Following these diagrams, the invariant amplitude for the decay \( Z \to l_B l_A \) can be written as follows:

\[
\mathcal{M}(Z \to l_B l_A) = \frac{i}{2} \frac{m_Z}{m^2_A - m^2_B} \bar{u}(p_2, s_2) \Lambda_\mu u(p_1, s_1) e^\mu(p, \lambda) ,
\]

where

\[
\Lambda_\mu = Y^{AB}_{\alpha\beta} [\gamma_\mu \left(g^A_V - g^A_B \gamma_5\right) \left(\not{p}_1 + m_B\right) \sigma^{\alpha\beta} - \sigma^{\alpha\beta} \left(\not{p}_2 + m_A\right) \gamma_\mu \left(g^A_V - g^A_B \gamma_5\right)] ,
\]

moreover \( g^A_V = \frac{1}{2} + 2s_W^2 \), and \( g^A_B = \frac{-1}{2} \). Squaring this amplitude leads to,

\[
|\mathcal{M}|^2 = \left(\frac{m_Z}{m_A}\right)^4 F(m_Z, m_A, m_B) ,
\]

with \( F(m_Z, m_A, m_B) \) a rather cumbersome expression whose explicit form is not necessary for our purposes. Working in the limits \( \frac{m_A}{m_Z} \to 0 \) and \( \frac{m_B}{m_Z} \to 0 \), which imply the kinematical conditions \( E_1 = E_2 = |p_1| = |p_2| = |p| = m_Z/2 \), the branching ratio for the decay \( Z \to l_B^\pm l_A^\mp \) becomes

\[
BR(Z \to l_B^\pm l_A^\mp) = \left(\frac{g^V_\mu}{\pi}\right)^2 \left(\frac{m_Z}{m_A}\right)^4 \left(\frac{m_Z}{\Gamma_Z}\right) \left| Y^{AB}_{\alpha\beta} Y^{AB}_{\lambda\rho} Z^{\alpha\beta\lambda\rho}\right| ,
\]

where the tensor \( Z^{\alpha\beta\lambda\rho} \) satisfies \( Z^{\alpha\beta\lambda\rho} = -Z^{\beta\alpha\lambda\rho} = -Z^{\alpha\beta\rho\lambda} = +Z^{\lambda\rho\alpha\beta} \) and is given by

\[
Z^{\alpha\beta\lambda\rho} = \frac{1}{m_Z^2} \left[ \left(p_1^\alpha p_1^\beta + p_2^\alpha p_2^\beta\right) g^{\gamma\lambda} - \left(p_1^\gamma p_1^\beta + p_2^\gamma p_2^\beta\right) g^{\alpha\lambda} + \left(p_1^\alpha p_1^\gamma + p_2^\alpha p_2^\gamma\right) g^{\beta\lambda} - \left(p_1^\alpha p_1^\gamma + p_2^\alpha p_2^\gamma\right) g^{\gamma\rho}\right] .
\]

The index symmetry properties of \( Z^{\alpha\beta\lambda\rho} \) and the already introduced kinematical approximation yield a branching ratio for the \( Z \) decay in terms of the function \( f_1(\hat{p}, e^{AB}, b^{AB}) \), which is also involved in the branching ratio Eq. (II.11) of the Higgs decay. Explicitly,

\[
BR(Z \to l_B^\pm l_A^\mp) = 2 \left(\frac{g^V_\mu}{\pi}\right)^2 \left(\frac{m_Z}{m_A}\right)^4 \left(\frac{m_Z}{\Gamma_Z}\right) \left| f_1(\hat{p}, e^{AB}, b^{AB})\right| .
\]

C. The electromagnetic decay \( l_A \to l_B \gamma \)

The most stringent bounds on LFV come from the electromagnetic decays \( l_A \to l_B \gamma \) and the three-body charged lepton decays \( l_A \to l_B l_C l_C \) (see (11) and (13)), both being of the same order of magnitude. Since the two-body decays \( l_A \to l_B \gamma \) under consideration are induced at tree level, due to the presence of the bilinear terms \( l_A l_B \) (see Fig. 3), it is clear that this type of decay dominates on the corresponding three-body one. Accordingly, we proceed to calculate the branching ratio for the decays \( l_A \to l_B \gamma \) and use the experimental limits on them to constrain the function \( f_1(\hat{p}, e^{AB}, b^{AB}) \) that consistently appears in the branching ratios (II.11) and (II.20).

The invariant amplitude for the decay \( l_A \to l_B \gamma \) is given by

\[
\mathcal{M}(l_A \to l_B \gamma) = \frac{is_W m_W}{m_A - m_B} \bar{u}(p_2, s_2) \Gamma_\mu u(p_1, s_1) e^\mu(q, \lambda) ,
\]
where
\[
\Gamma_{\mu} = Y_{\alpha \beta}^A \left[ \sigma^{\alpha \beta} (q_2^f + m_A) \gamma_{\mu} - \gamma_{\mu} (q_1^f + m_B) \sigma^{\alpha \beta} \right].
\] (II.22)

Although it is not evident, it can be shown that this amplitude preserves gauge invariance as it satisfies the simple Ward identity
\[
q^\mu \Gamma_{\mu} = 0.
\] (II.23)

Once the amplitude is squared, the corresponding branching ratio can be written as follows:
\[
BR(l_A \rightarrow l_B \gamma) = \left( \frac{\alpha}{2\pi} \right) \left( \frac{m_W}{m_A} \right)^2 \left( \frac{m_A}{\Gamma_A} \right) \left( 1 - \frac{m_B^2}{m_A^2} \right) \left| Y_{\alpha \beta}^A Y_{\lambda \rho}^B R^{\alpha \beta \lambda \rho} \right|,\]
where \(\Gamma_A\) is the total decay width of the charged lepton \(l_A\) and
\[
R^{\alpha \beta \lambda \rho} = g^{\alpha \lambda} g^{\beta \rho} - g^{\alpha \rho} g^{\beta \lambda} + \frac{m_A^4}{(m_A^2 - m_B^2)^2} A^{\alpha \beta \lambda \rho} + \frac{m_B^4}{(m_A^2 - m_B^2)^2} B^{\alpha \beta \lambda \rho},
\] (II.25)
where
\[
A^{\alpha \beta \lambda \rho} = A^{\alpha \beta \lambda \rho}(p_1, p_2),
\]
(II.26a)
\[
B^{\alpha \beta \lambda \rho} = B^{\alpha \beta \lambda \rho}(p_2, p_1),
\]
(II.26b)
\[
A^{\alpha \beta \lambda \rho}(p_1, p_2) = \left[ p_2^\beta (p_i - 3p_j)^\lambda + p_1^\beta (p_i + p_j)^\lambda \right] g^{\alpha \rho} - \left[ p_2^\rho (p_i - 3p_j)^\lambda + p_1^\rho (p_i + p_j)^\lambda \right] g^{\beta \rho} - \left[ p_2^\beta (p_i - 3p_j)^\rho + p_1^\beta (p_i + p_j)^\rho \right] g^{\alpha \lambda} - \left[ p_2^\rho (p_i - 3p_j)^\rho + p_1^\rho (p_i + p_j)^\rho \right] g^{\beta \lambda}.
\] (II.27)

In this expression, \(i, j = 1, 2\). Notice that \(A^{\alpha \beta \lambda \rho} = -A^{\beta \alpha \lambda \rho} = -A^{\alpha \beta \rho \lambda} = +A^{\beta \alpha \rho \lambda}\).

Depreciating \(m_B\) against \(m_A\), the branching ratio acquires a simpler form, namely
\[
BR(l_A \rightarrow l_B \gamma) = \left( \frac{\alpha}{2\pi} \right) \left( \frac{m_W}{m_A} \right)^2 \left( \frac{m_A}{\Gamma_A} \right) \left| Y_{\alpha \beta}^A Y_{\lambda \rho}^B \left( g^{\alpha \lambda} g^{\beta \rho} - g^{\alpha \rho} g^{\beta \lambda} + A^{\alpha \beta \lambda \rho} \right) \right|.\]
(II.28)

Just as for the decays \(H \rightarrow l_A^+ l_B^-\) and \(Z \rightarrow l_A^+ l_B^-\), we can write the branching ratio Eq. (II.28) in terms of the electric- and magnetic-like vectors \(e^{AB}\) and \(b^{AB}\) contained in \(Y_{\alpha \beta}^A\) as follows
\[
BR(l_A \rightarrow l_B \gamma) = \left( \frac{\alpha}{2\pi} \right) \left( \frac{m_W}{m_A} \right)^2 \left( \frac{m_A}{\Gamma_A} \right) \left\| f_2(\tilde{p}, e^{AB}, b^{AB}) \right\|,\]
(II.29)
where
\[
\left\| f_2(\tilde{p}, e^{AB}, b^{AB}) \right\| = \left( e^{AB} \right)^2 + \left( b^{AB} \right)^2 - 2 \tilde{p} \cdot (e^{AB} \times b^{AB}) + 3(\tilde{p} \cdot e^{AB})^2 + 3(\tilde{p} \cdot b^{AB})^2,\]
(II.30)
and \(\tilde{p}\) stands for the normalized momentum vector of the lepton \(l_B\).

\[D.\] Discussion

In order to bound the branching ratios for the decays \(H \rightarrow l_A^+ l_B^-\) and \(Z \rightarrow l_A^+ l_B^-\), we will use the experimental limits on the electromagnetic transitions \(l_A \rightarrow l_B \gamma\) given above. So, we demand
\[
BR(l_A \rightarrow l_B \gamma) < BR_{Exp}(l_A \rightarrow l_B \gamma),\]
(II.31)
which leads to
\[ \|f_2(\hat{p}, e^{AB}, b^{AB})\| < \left( \frac{2\pi}{s_W} \right) \left( \frac{m_A}{m_W} \right)^2 \left( \frac{\Gamma_A}{m_A} \right) BR_{\exp}(l_A \rightarrow l_B\gamma). \] (II.32)

Using the experimental limits [11], one obtains the following severe bounds:
\[
\begin{align*}
\|f_2(\hat{p}, e^{AB}, b^{AB})\| &< 3.0 \times 10^{-34}, \\
\|f_2(\hat{p}, e^{\mu e}, b^{\mu e})\| &< 1.0 \times 10^{-21}.
\end{align*}
\] (II.33a, b)

On the other hand, to predict the branching ratios \(BR(H \rightarrow l_A l_B\gamma)\) and \(BR(Z \rightarrow l_A l_B\gamma)\), we need to estimate the value of \(\|f_1(\hat{p}, e^{AB}, b^{AB})\|\) relative to \(\|f_2(\hat{p}, e^{AB}, b^{AB})\|\). To this end, we consider the following scenarios:

- **Scenario 1**: \(e^{AB} \times b^{AB} \neq 0\). Within this scenario, we can consider the following two possibilities
  (a) The unitary vector \(\hat{p}\) lies on the plane defined by \(e^{AB}\) and \(b^{AB}\), \(\hat{p} \cdot (e^{AB} \times b^{AB}) = 0\). So \(\|f_1(\hat{p}, e^{AB}, b^{AB})\|\) and \(\|f_2(\hat{p}, e^{AB}, b^{AB})\|\) reduce to
  \[
  \begin{align*}
  \|f_1(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 - (\hat{p} \cdot e^{AB})^2, \\
  \|f_2(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 + 3(\hat{p} \cdot e^{AB})^2.
  \end{align*}
  \]
  thus
  \[ \|f_2(\hat{p}, e^{AB}, b^{AB})\| > \|f_1(\hat{p}, e^{AB}, b^{AB})\|. \] (II.34)

  (b) The unitary vector \(\hat{p}\) is anti-parallel to \((e^{AB} \times b^{AB})\), then \(\hat{p} \cdot e^{AB} = \hat{p} \cdot b^{AB} = 0\). And we have the following reductions:
  \[
  \begin{align*}
  \|f_1(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 - 2|\hat{p}| \left| e^{AB} \times b^{AB} \right|, \\
  \|f_2(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 + 2|\hat{p}| \left| e^{AB} \times b^{AB} \right|.
  \end{align*}
  \]
  so we have again
  \[ \|f_2(\hat{p}, e^{AB}, b^{AB})\| > \|f_1(\hat{p}, e^{AB}, b^{AB})\|. \] (II.35)

- **Scenario 2**: \(e^{AB} \times b^{AB} = 0\). In this case, \(\|f_1(\hat{p}, e^{AB}, b^{AB})\|\) and \(\|f_2(\hat{p}, e^{AB}, b^{AB})\|\) reduce to
  \[
  \begin{align*}
  \|f_1(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 - (\hat{p} \cdot e^{AB})^2, \\
  \|f_2(\hat{p}, e^{AB}, b^{AB})\| &= \left| e^{AB} \right|^2 + \left| b^{AB} \right|^2 + 3(\hat{p} \cdot e^{AB})^2.
  \end{align*}
  \]
  and again we conclude
  \[ \|f_2(\hat{p}, e^{AB}, b^{AB})\| > \|f_1(\hat{p}, e^{AB}, b^{AB})\|. \] (II.36)
From the above results, we conclude that whenever any of the previous scenarios are met, we have

\[ BR(H \rightarrow l^+_Ak^+_\ell_B) < \frac{1}{4\pi} \left( \frac{m_H}{\Gamma_H} \right) \left( \frac{m_H}{m_A} \right)^4 \parallel f_2(\hat{p}, e^{AB}, b^{AB}) \parallel, \]  

\[ \text{(II.37)} \]

\[ BR(Z \rightarrow l^+_Ak^+_\ell_B) < 2 \left( \frac{g_Y^2 + (g_Z^2)}{\pi} \right) \left( \frac{m_Z}{\Gamma_Z} \right) \left( \frac{m_Z}{m_A} \right)^4 \parallel f_2(\hat{p}, e^{AB}, b^{AB}) \parallel. \]  

\[ \text{(II.38)} \]

Comparing these inequalities with the general bounds \[ \parallel f_2(\hat{p}, e^{AB}, b^{AB}) \parallel, \] imply the following Higgs branching ratios:

\[ BR(H \rightarrow \mu^+\nu^\mp) < 1.8 \times 10^{-18}, \]  

\[ \text{(II.39)} \]

\[ BR(H \rightarrow \tau^+\nu^\mp) < 4.2 \times 10^{-11}. \]  

\[ \text{(II.40)} \]

In a similar fashion, the corresponding branching ratios of the $Z$ gauge boson are given by

\[ BR(Z \rightarrow \mu^+\nu^\mp) < 5.7 \times 10^{-21}, \]  

\[ \text{(II.41)} \]

\[ BR(Z \rightarrow \tau^+\nu^\mp) < 2.0 \times 10^{-12}. \]  

\[ \text{(II.42)} \]

From these results, it is evident that signals of lepton flavor violation mediated by the Higgs or the $Z$ gauge boson are severely suppressed if induced in a renormalizable context of Lorentz violation. Behind this behavior lies the fact that both the Higgs and $Z$ boson decays are induced at the same order as the electromagnetic ones, which are severely constrained by the experiment. Below, we will show that a quite different scenario emerges when the SME is enlarged to comprise nonrenormalizable lepton flavor violating effects.

### III. Lorentz Violating Yukawa Sector: Nonrenormalizable Extension

In this section, we explore the implications of a Lorentz violating extension to the Yukawa sector beyond the renormalizable structure. The idea is to introduce an extension of the Yukawa sector via the lowest possible dimension terms that generates LFV mediated by the Higgs boson (and also perhaps by the $Z$ gauge boson) at the tree level, but not by the photon. This means that this effect cannot be generated by the photon at tree level, but only at one-loop or higher orders. In other words, we will consider a Lorentz violating nonrenormalizable extension of the Yukawa sector where LFV electromagnetic transitions are naturally suppressed in a perturbative context. It is not difficult to convince oneself that the unique\(^1\) lowest dimension extension of the Yukawa sector, with the properties specified above, is given by the following dimension-five $SU_L(2) \times U_Y(1)$–invariant Lagrangian

\[ \mathcal{L}^N_{Y} = -Y^{\alpha AB}_{\alpha} \bar{L}_A \Phi_l^{\alpha} \Phi_{lB} + \text{h.c.}, \]  

\[ \text{(III.1)} \]

where $D^\alpha$ is the covariant derivative of the the electroweak group in the doublet representation. In this expression, $Y^{\alpha AB}_{\alpha}$ is a matrix in the flavor space with units of inverse of mass. In the unitary gauge and after using the standard unitary mapping that transforms gauge fields into mass eigenstate fields (see Eq. \[ \text{(II.3)} \]), one obtains

\[ \mathcal{L}^N_{Y} = -\delta^{\alpha} H \bar{E} Y_{\alpha} E - im_Z c_{2W} \left( 1 + \frac{H}{v} \right) Z^\alpha \bar{E} Y_{\alpha} \gamma_5 E, \]  

\[ \text{(III.2)} \]

where $Y_{\alpha} = \frac{1}{\sqrt{2}} V^H_L Y_{\alpha} V^H_R$ is the matrix responsible for LFV. As in the renormalizable case, it will be assumed that the matrix $Y_{\alpha}$ is real and symmetric. In addition, we introduced the shorthand notation $c_{2W} \equiv c^2_W - s^2_W$.

Directly from the structure of $\mathcal{L}^N_{Y}$, the LFV electromagnetic transitions are naturally suppressed as they first arise at one-loop level, whereas LFV effects mediated by the Higgs boson or the $Z$ gauge boson are induced at tree level. The respective vertex functions for the $H(p)l_A l_B$ and $Zl_A l_B$ couplings are $i\rho^{\alpha} Y^{\alpha AB}_{\alpha}$ and $m_Z c_{2W} \gamma_5 Y^{\alpha AB}_{\alpha}$. Hence we are now able to calculate branching ratios of the different decays we are interested in.

---

\(^1\) There is also the dimension-five $SU_L(2) \times U_Y(1)$–invariant operator $D^\alpha L_A \Phi_l^{\alpha} \Phi_{lB} + \bar{L}_A \Phi \bar{D}^{\alpha} \Phi_{lB}$; however, this is related to Eq. \[ \text{(III.1)} \] via a surface term.
A. The decay $H \to l_B^\pm l_B^\mp$

The amplitude for the decay $H \to l_B^\pm l_B^\mp$ is given by

$$\mathcal{M}(H \to l_B^\pm l_B^\mp) = i \left( p^a Y_{AB}^\alpha \right) \left[ \bar{v}(p_2, s_2) u(p_1, s_1) \right]$$

$$= i \left( p^0 Y_{0B}^\alpha \right) \left[ \bar{v}(p_2, s_2) u(p_1, s_1) \right]$$

$$= i \left( m_H Y_0^\alpha \right) \left[ \bar{v}(p_2, s_2) u(p_1, s_1) \right] ,$$

where the last two expressions are valid at the rest frame of the Higgs boson. The Lagrangian that defines the Lorentz violating and nonrenormalizable extension of the Yukawa sector, Eq. (III.3), can be thought as an effective Lagrangian derived from a fundamental Lorentz-invariant theory that contains interactions among a certain well behaved vector field $Y_\alpha(x)$, the leptonic fields and the Higgs boson, where the breakdown of the Lorentz symmetry arises from a timelike nonzero expectation value, $\langle Y_\alpha \rangle_0 = (Y_0^{AB}, 0, 0, 0)$, acquired by $Y_\alpha(x)$ at the rest frame of the Higgs boson. As neither such a fundamental theory or symmetry breaking mechanism is relevant for our discussion, we will assume the constant time-like vector $Y_0^{AB} = (Y_0^{AB}, 0, 0, 0)$ as an effective coupling constant.

In order to consider the complete process $H \to l_B^\pm l_A^\mp l_B^\mp a$ factor of 2 must be included in Eq. (III.3) after the amplitude is squared; therefore, the branching ratio for this decay can be written as follows:

$$BR(H \to l_B^\pm l_A^\mp l_B^\mp) = \frac{1}{4\pi} \left( \frac{m_H}{\Gamma_H} \right) f(m_H, m_A, m_B) \left( m_H Y_0^{AB} \right)^2 ,$$

where

$$f(m_H, m_A, m_B) = \left( 1 - \frac{m_A^2 + m_B^2}{m_H^2} \right) \sqrt{1 - \left( \frac{m_A + m_B}{m_H} \right)^2} \sqrt{1 - \left( \frac{m_A - m_B}{m_H} \right)^2} .$$

In the limit where the lepton masses $m_A$ and $m_B$ are disregarded against the Higgs mass $m_H$, the function $f(m_H, m_A, m_B) \to 1$ so the branching ratio acquires the following simple form:

$$BR(H \to l_B^\pm l_A^\mp l_B^\mp) = \frac{1}{4\pi} \left( \frac{m_H}{\Gamma_H} \right) \left( m_H Y_0^{AB} \right)^2 .$$

B. The decay $Z \to l_B^\pm l_B^\mp$

In a similar fashion, an exact calculation of the branching ratio for the decay $Z \to l_B^\pm l_A^\mp l_B^\mp$, leads to

$$BR(Z \to l_B^\pm l_A^\mp l_B^\mp) = \frac{c_{2W}}{12\pi} \left( \frac{m_Z}{\Gamma_Z} \right) g(m_Z, m_A, m_B) \left( m_Z^2 Y_0^{2AB} Y^{AB\alpha} + (p^a Y_0^{AB})^2 \right) ,$$

where $p^a = (p^0, 0, 0, 0)$ is the momentum of the $Z$ gauge boson in its rest frame, and the function $g(m_Z, m_A, m_B)$ is given by

$$g(m_Z, m_A, m_B) = \left[ 1 - \left( \frac{m_A - m_B}{m_Z} \right)^2 \right]^{3/2} \left[ 1 - \left( \frac{m_A + m_B}{m_Z} \right)^2 \right]^{1/2} .$$

In the limit $(m_A/m_Z), (m_B/m_Z) \to 0$, and taking into account that $Y_0^{AB}$ is time-like, the branching ratio reduces to

$$BR(Z \to l_B^\pm l_B^\mp) = \frac{c_{2W}}{6\pi} \left( \frac{m_Z}{\Gamma_Z} \right) \left( m_Z Y_0^{AB} \right)^2 .$$

---

2 Similar ideas have been used in the so-called bumblebee models, which consider that the photons and gravitons could emerge as Goldstone bosons from a spontaneous symmetry breaking that incorporates vacuum expectation values of the corresponding gauge fields [21].
leads to the most important bound on the \( Y \) amplitude for the decay Eq. (III.2), we can calculate the three-body decay one-loop level in contrast to the renormalizable case where they arise at tree level. Nevertheless, from the extension Eq. (III.2), we can calculate the three-body decay \( l_A \rightarrow l_B l_C l_C \) induced at tree-level by the \( Z \) gauge boson, this decay leads to the most important bound on the \( Y_{0AB} \) scale\(^3\). In accordance with the diagrams in the Fig. 4, the invariant amplitude for the decay \( l_A \rightarrow l_B l_C l_C \) is

\[
\mathcal{M}(l_A \rightarrow l_B l_C l_C) = -\frac{g c_{2W}}{2 c_W m_Z} \left[ \bar{u}(p_2, s_2) \gamma_5 u(p_1, s_1) \right] \left[ \bar{v}(q_2, s_2) \gamma^\alpha (g_V^l - g_A^l) \gamma_\alpha u(q_1, s_1) \right],
\]

where we have neglected the contribution of the longitudinal component of the \( Z \) propagator, as it is proportional to \((m_A/m_Z)^2\). In the limit \( m_B, m_C \rightarrow 0 \), the branching ratio for this decay can be rewritten as follows:

\[
BR(l_A \rightarrow l_B l_C l_C) = \frac{1}{256\pi^3} \left( \frac{m_A}{\Gamma_A} \right) \int_0^1 dx \int_0^{1-x} dy |\mathcal{M}|^2,
\]

where

\[
|\mathcal{M}|^2 = \frac{g^2 c_{2W}}{2 c_W} \left[ (g_V^l)^2 + (g_A^l)^2 \right] \left( \frac{m_A}{m_Z} \right)^4 \left| m_Z Y_{0AB} \right|^2 f(x, y),
\]

and

\[
f(x, y) = (2 - x - y)(1 - x - y + xy).
\]

Solving the integral in the Eq. (III.11),

\[
BR(l_A \rightarrow l_B l_C l_C) = \left( \frac{3}{10} \right) \left( \frac{\alpha}{64\pi^2} \right) \left( \frac{c_{2W}}{s_{2W}} \right)^2 \left[ (g_V^l)^2 + (g_A^l)^2 \right] \left( \frac{m_A}{\Gamma_A} \right) \left( \frac{m_A}{m_Z} \right)^4 \left| m_Z Y_{0AB} \right|^2.
\]

D. Discussion

We now use the experimental constraints on the three-body decays of charged leptons to get bounds on the \( Y_{0AB} \) scale. By demanding

\[
BR(l_A \rightarrow l_B l_C l_C) < BR_{\text{Exp}}(l_A \rightarrow l_B l_C l_C),
\]

one obtains

\[
\left| m_Z Y_{0AB} \right|^2 < \left( \frac{10}{3} \right) \left( \frac{64\pi^2}{\alpha} \right) \left( \frac{s_{2W}}{c_{2W}} \right)^2 \frac{1}{(g_V^l)^2 + (g_A^l)^2} \left( \frac{\Gamma_A}{m_A} \right) \left( \frac{m_Z}{m_A} \right)^4 BR_{\text{Exp}}(l_A \rightarrow l_B l_C l_C).
\]

\(^3\) This decay can also be induced by the Higgs boson, but due to the small SM coupling in \( H l_C l_C \), this contribution is quite suppressed in comparison to the \( Z \) gauge boson contribution.
So, using the experimental limits \([2]\) on these decays, the following bounds are obtained:

\[
\left\| m_2 Y_0^{\mu e} \right\|^2 < 1.2 \times 10^{-12}, \quad (\text{III.17})
\]
\[
\left\| m_2 Y_0^{\tau \mu} \right\|^2 < 2.0 \times 10^{-7}. \quad (\text{III.18})
\]

These bounds allow us to estimate the branching ratios of the LFV decays of the Higgs and Z bosons.

Considering the Higgs decay, we obtain the following limits:

\[
BR(H \rightarrow \mu^\pm e^\mp) < 4.1 \times 10^{-9}, \quad (\text{III.19})
\]
\[
BR(H \rightarrow \tau^\pm \mu^\mp) < 6.8 \times 10^{-4}, \quad (\text{III.20})
\]

which are significantly larger than those obtained in the renormalizable setting (see Eqs. (II.39) and (II.40)). In particular, the \(\tau^\pm \mu^\mp\) channel is remarkable from the experimental point of view, as it may be at the reach of future experiments. Worth noticing is the comparable order of magnitude between the branching ratio \(BR(H \rightarrow \tau^\pm \mu^\mp)\) reported in this paper and that one described in the context of LFV effective field theories that preserve Lorentz invariance \([9]\).

As far as the Z gauge boson decays are concerned, their branching ratios are bounded by

\[
BR(Z \rightarrow \mu^\pm e^\mp) < 0.7 \times 10^{-12}, \quad (\text{III.21})
\]
\[
BR(Z \rightarrow \tau^\pm \mu^\mp) < 1.1 \times 10^{-7}. \quad (\text{III.22})
\]

These branching ratios are more constrained in comparison with those involving the Higgs boson, this is a direct consequence of the three orders of magnitude by which the Z decay width exceeds the \(H\) decay width.

It is interesting to estimate the energy scales above which LFV, emerging from Lorentz violation, can arise. Let \(Y_0^{AB} \equiv 1/\Lambda_{LFV}^{AB}\) be the new physics scale. From Eqs. (III.17,III.18), the following bounds are derived:

\[
\Lambda_{LFV}^{\mu e} > 8.3 \times 10^4 \text{ TeV}, \quad (\text{III.23})
\]
\[
\Lambda_{LFV}^{\tau \mu} > 204 \text{ TeV}. \quad (\text{III.24})
\]

It is worth comparing these scales to the Fermi scale \((v)\) through the ratio \(\epsilon_{LFV}^{AB} \equiv v/\Lambda_{LFV}^{AB}\). Using the above results, one obtains

\[
\epsilon_{LFV}^{\mu e} = 3.0 \times 10^{-6}, \quad (\text{III.25})
\]
\[
\epsilon_{LFV}^{\tau \mu} = 1.2 \times 10^{-3}. \quad (\text{III.26})
\]

From these bounds, it is concluded that if the phenomenon of LFV is induced by LV, it occurs at very high energies, in particular, those transitions between the second and the first families.

IV. CONCLUSIONS

It is possible that the electromagnetic interaction exactly preserves the leptonic flavor, as it is suggested by the current experimental limits on photon-mediated transitions among charged leptons. However, lepton flavor violation could occur in nature via Higgs boson decays; at the end, this particle has a special role in the generation of the mass spectrum on the SM. The mass is an important quantum number which is correlated with the flavor of a particle, \(i.e.,\) it is an intrinsic property directly associated with the identity of any elementary particle. The Higgs boson is the only particle in the SM that can distinguish the flavor through the mass because it couples to any massive particle with a coupling proportional to the mass itself. Lepton flavor violation may also be induced by the Z gauge boson, the current experimental constraints on such decays are more flexible than those existing for the electromagnetic processes.

In this work, we have presented the analysis for lepton flavor violation mediated by the Higgs boson, the Z gauge boson, and the photon in the context of an SME viewed as an effective field theory that incorporates non-conserved CPT and Lorentz violation in a model-independent manner. We separately explored the aforementioned processes within renormalizable and nonrenormalizable extensions of the SM Yukawa sector. In the renormalizable extension, the lepton flavor violation is induced at tree level by the three neutral bosonic particles of the SM; it was found that the presence of LFV induced in this way is quite suppressed due to severe constraints arising from experimental limits on the electromagnetic transitions \(l_A \rightarrow l_B \gamma\). In this context, the Higgs decays into channels \(\mu^\pm e^\mp\) and \(\tau^\pm \mu^\mp\)
have branching ratios of the order of $10^{-18}$ and $10^{-11}$, respectively. About the $Z$ boson decays into these channels, the respective branching ratios are of order of $10^{-20}$ and $10^{-12}$. These practically unobservable branching ratios are the consequence of the almost prohibited electromagnetic transitions $l_A \rightarrow l_B \gamma$, generated at tree level in this renormalizable extension of the SM. On the other hand, in the nonrenormalizable extension of the Yukawa sector, lepton flavor violation is generated at tree level via both the Higgs and the $Z$ gauge bosons. In this scenario, lepton flavor violation mediated by the photon is naturally suppressed as this effect contributes at one-loop level. In this context, the Higgs decays into the channels $l^+_A l^-_B$ are proportional to the time component of the vector $Y^{AB}_\mu$ that characterizes the flavor violating transitions. Assuming a time-like $Y^{AB}_\mu$ vector, simple expressions for the $Z$ decays into $l^+_A l^-_B$ were also derived. Under this assumption on $Y^{AB}_\mu$, the tree-level contribution of a virtual $Z$ gauge boson to the three-body decay $l_A \rightarrow l_B l^C \ell_C$ was calculated. Then, the experimental constraints on these decays were used to bound the time-like $Y^{AB}_\mu$ vector and thus allows us to predict the branching ratios for the Higgs and $Z$ bosons decays into the $\mu^\pm e^\mp$ and $\tau^\pm \mu^\mp$ channels. It was found that $BR(H \rightarrow \mu^\pm e^\mp) < 4.1 \times 10^{-9}$ and $BR(H \rightarrow \tau^\pm \mu^\mp) < 6.8 \times 10^{-4}$, whereas $BR(Z \rightarrow \mu^\pm e^\mp) < 7.0 \times 10^{-13}$ and $BR(Z \rightarrow \tau^\pm \mu^\mp) < 1.1 \times 10^{-7}$. The scales characterizing this class of new physics effects are $\Lambda^{\mu e}_{LFV} > 8.3 \times 10^3$ TeV, for transitions between the second and first families, and $\Lambda^{\tau \mu}_{LFV} > 204$ TeV, for transitions from the third to the second family. It can be seen from these results that, despite of relatively high new physics energy scale relative to the Fermi scale, the Higgs boson decay $H \rightarrow \tau^\pm \mu^\mp$ becomes compelling, as it can reach a branching ratio of almost $10^{-3}$ and thus be within the range of future measurements.
