Abstract: In this work, magnetic CuFe2O4/Ag nanoparticles activated by porous covalent organic frameworks (COF) was fabricated to evaluate the heterogenous reduction of 4-nitrophenol (4-NP). The core-shell CuFe2O4/Ag@COF was successfully prepared by polydopamine reduction of silver ions on CuFe2O4 nanoparticles, followed by COF layer condensation. By integrating the intrinsic characteristics of the magnetic CuFe2O4/Ag core and COF layer, the obtained nanocomposite exhibited features of high specific surface area (464.21 m2 g⁻¹), ordered mesoporous structure, strong environment stability, as well as fast magnetic response. Accordingly, the CuFe2O4/Ag@COF catalyst showed good affinity towards 4-NP via π-π stacking interactions and possessed enhanced catalytic activity compared with CuFe2O4/Ag and CuFe2O4@COF. The pseudo-first-order rate constant of CuFe2O4/Ag@COF (0.77 min⁻¹) is 3 and 5 times higher than CuFe2O4/Ag and CuFe2O4@COF, respectively. The characteristics of bi-catalytic CuFe2O4/Ag and the porous COF shell of CuFe2O4/Ag@COF made a contribution to improve the activity of 4-NP reduction. The present work demonstrated a facile strategy to fabricate COF-activated nano-catalysts with enhanced performance in the fields of nitrophenolic wastewater treatment.

1. Introduction

Nitrophenols are mutagenic and refractory aromatic pollutants commonly found in various industrial and agricultural wastewaters. Among the three isomeric nitrophenols, 4-nitrophenol (4-NP) is more detrimental to pose a threat to both the environment and the public [1]. Generally, two conventional clean-up techniques are used for the removal of 4-NP: (1) permanent removal of target contaminants, and (2) conversion into less- or non-toxic forms. A technique related to the latter pattern would be desirable because of the production of p-aminophenol (4-AP), which is an important intermediate in the productions of pharmaceuticals, dyes, pigments and pesticides [2–4]. Therefore, high-efficiency and recycled catalysts have been desired for 4-NP reduction.

Catalytic reduction using noble metals as catalysts have been widely employed for 4-NP reduction due to the high surface areas and the exposed active atoms. However, due to the high surface free energy, noble metals tend to agglomerate, thus leading to obvious decrease of the
catalytic activities [5]. To improve the catalytic activity and stability, it would be feasible to immobilize noble metals on a matrix, especially another catalytic component, which would reduce its aggregation as well as improve the catalytic performance in contrast with monometallic counterparts [6,7].

Magnetic CuFe2O4 nanoparticles have been used in several water-treatment applications due to their desirable stability, easy separation and remarkable catalysis [8,9]. Thus, instead of single-component metals, noble metal@CuFe2O4 catalyst would reduce the aggregation of noble metal nanoparticles and maximize the synergistic effects of the bi-catalyst [10,11]. However, because of inter-particle aggregation and a non-porous structure, noble metal@CuFe2O4 nanoparticles still have disadvantages such as a limited stability and low surface area. Hence, active noble metal@CuFe2O4 nanoparticles dispersed on porous solid supports are gaining increasing interest for more effective and versatile catalysis.

Covalent organic frameworks (COF) are an emerging type of porous materials being extensively studied due to their excellent properties and broad applications [12–15]. In comparison with their materials similar to metal organic frameworks (MOF), robust covalent bonds on COF enable it to overcome the problems of water and moisture instability [16,17]. The fascinating features such as low density, high and regular porosity, tunable pore size [18,19], render them promising candidates in diverse applications in catalysis, gas storage, adsorption, optoelectricity and chemical sensors [20–24]. Recently, some research has reported that COF can heterogeneously nucleate and grow on the surface of different matrices to construct core-shell structure composite materials (graphene, carbon nanotubes, Fe3O4 and alumina, etc.) [25–28]. Incorporation of the merits of COF and nanosized components for core-shell structure nanocomposites synthesis, the aggregation of nanosized cores can be effectively impeded while allowing facile surface modification. Therefore, based on the feasibly tuned properties by the in-built covalent bond architecture, it can be anticipated that COF can be used as more suitable scaffolds than other kinds of porous materials for fabricating core-shell structured noble metal@CuFe2O4 nanocomposite.

Herein, a facile synthesis strategy of core-shell structure nanocomposite was developed to integrate magnetic CuFe2O4/Ag nanoparticles and porous COF for 4-NP reduction. Due to the outstanding stability and chemical robustness [29], TAPB-DMTP (1,3,5-tris(4-aminophenyl)benzene and 2,5-dimethoxyterephaldehyde, respectively) was utilized as the COF shell material coated on the surface of CuFe2O4/Ag nanoparticles via the polypepyrrolidone (PVP)-assisted encapsulation strategy [30]. Meanwhile, the unique π–π electron structure of COF and strong magnetic property of magnetic CuFe2O4/Ag@COF composites can provide both affinity sites and the adsorption forces for reaction targets, as well as facilitate the rapid and easy separation. In addition, the high surface area of the TAPB-DMTP coating ensures high loading capacity of the reaction substrates. Accordingly, the as-prepared porous CuFe2O4/Ag@COF nanocomposite exhibited a high surface area, large number of affinity sites and strong magnetic property owing to the combination of the merits of CuFe2O4/Ag and TAPB-DMTP. By virtue of the unique features, CuFe2O4/Ag@COF acted as the recyclable catalyst for 4-NP reduction by NaBH4 and showed enhanced catalytic activities and stability.

2. Experimental

2.1. Materials

1,3,5-tris(4-aminophenyl)benzene (TAPB), 2,5-dimethoxyterephaldehyde (DMPT) and dopamine hydrochloride (DA·HCl), polyethylene glycol (PEG-6000) and polyvinylpyrrolidone (PVP, Mw = 5500) were purchased from Aladdin Co. Ltd (China). Cupric chloride anhydrous (CuCl2), ferric chloride hexahydrate (FeCl3·6H2O), ammonium acetate (NH4Ac), ethylene glycol (EG), silver nitrate (AgNO3), NaCH2COOH (NaAc), CH3COOH (HAc), 4-nitrophenol (4-NP), sodium borohydride (NaBH4), and other chemicals and reagents were purchased from Sinopharm Chemical Reagent Co. Ltd (Xi’an, China).
2.2. Measurements

Sample morphologies were characterized by field-emission scanning electron microscopy (SEM, Hitachi S-4800, Hitachi, Japan) and transmission electron microscopy (TEM, TECNAI G² TF20, Hillsboro, OH, USA). Fourier transform infrared (FTIR, Bruker VERTEX 70, Karlsruhe, Germany) spectra were obtained with a wavelength range of 4000 to 400 cm⁻¹. Powder X-ray diffraction spectra (XRD, Bruker, D8-Advance, Karlsruhe, Germany) were measured with Cu Kα radiation (λ = 1.542 Å) in the angle range 5–70° (2θ). The specific surface area and pore size distribution were calculated by the Brunauer–Emmett–Teller (BET, ASAP2460, Atlanta, GA, USA) and Barrett–Joyner–Halanda (BJH) methods. Thermogravimetric analysis (TGA) was recorded on a TG apparatus (NETZSCH STA 449F3-1053-M, Selb, Germany) by heating the sample in the range 30–800 °C at a constant rate of 10 °C min⁻¹ under a N₂ atmosphere. Magnetic hysteresis loops at room temperature were obtained using a vibrating sample magnetometer VSM 7304 (Lakeshore, Columbus, OH, USA). The chemical composition of CuFe₂O₄/Ag and CuFe₂O₄/Ag@COF were characterized by X-ray photoelectron spectroscopy (XPS, AXIS SUPRA, Manchester, UK). The absorbance of the reaction solution was determined by ultraviolet-visible (UV-Vis) spectra (Shimadzu UV-2501 PC spectrometer, Suzhou, China).

2.3. Synthesis of CuFe₂O₄/Ag Nanoparticles

CuFe₂O₄ nanoparticles were synthesized according to the reported method [31]. Then the Ag nanoparticle was assembled on CuFe₂O₄ according to a polydopamine (PDA)-assisted reduction process [32]. Typically, 30 mg of CuFe₂O₄ nanoparticles were dispersed in 25 mL Tris buffer solution (10 mM, pH = 8.5), followed by adding 50 mg of DA·HCl into the mixture and mechanically stirred for 2 h at room temperature. Then the black powder was collected by a magnet, washed with ethanol and deionized water. For the preparation of CuFe₂O₄/Ag nanoparticles, silver ammonia solution was firstly prepared by adding ammonia aqueous solution (2 wt%) into 10 mg·mL⁻¹ AgNO₃ solution until the brown precipitation was just dissolved. Then 50 mg of PDA-modified CuFe₂O₄ were added to 25 mL silver ammonia solution, and the mixture was mechanically stirred for 6 h at room temperature. The product was collected with a magnet and washed with ethanol and deionized water, then dried under vacuum at 60 °C over night.

2.4. Preparation of Core-Shell Structured CuFe₂O₄/Ag@COF Nanocomposites

The synthesis of core-shell structured CuFe₂O₄/Ag@COF nanocomposites was carried out as a modified method [33]. Firstly, CuFe₂O₄/Ag nanoparticles were stabilized with PVP. In brief, the CuFe₂O₄/Ag nanoparticles (50 mg) were suspended in water (50 mL), and a solution of PVP (25 mg) in water (50 mL) was added dropwise to the above solution under stirring. The mixture was further stirred at room temperature for 12 h, washed three times with methanol, and final dispersed in methanol (10 mL). Secondly, the PVP-stabilized CuFe₂O₄/Ag nanoparticles were sonicated for 30 min under stirring, and 4 mL 1,4-dioxane-butanol (v/v = 1/1) containing TAPB (0.03 mmol) and DMTP (0.045 mmol) was added to the suspension. After that, aqueous acetic acid (12 M, 0.15 mL) was slowly appended to the mixture. Then, the reaction was allowed to conduct at room temperature for 2 h. After another aqueous acetic acid (12 M, 0.45 mL) was added to the suspension, the reaction was further stirred at 70 °C for 24 h. The product (CuFe₂O₄/Ag@COF) was naturally cooled to room temperature and collected with the help of a magnet. After being washed with tetrahydrofuran and acetone several times, the product was dried in vacuum at 80 °C overnight.

The CuFe₂O₄@COF nanocomposite was prepared according to the above method by adding CuFe₂O₄ nanoparticles.

2.5. Catalytic Reduction of 4-Nitrophenol (4-NP)

Catalytic activities of the CuFe₂O₄/Ag@COF nanocomposite were evaluated by UV-Vis spectroscopy through the reduction of 4-NP to 4-AP at room temperature, using NaBH₄ as a reductant. 200 μL of 4-NP solution (5 mM), 0.45 mL of freshly prepared NaBH₄ aqueous solution
(200 mM), and 2.35 mL deionized water were added into a standard quartz cuvette. The mixture solution turns from light yellow to bright yellow. Subsequently, 2 mg of CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF was dispersed to the above mixture. Then the intensity of the absorption peak at 400 nm was monitored by UV-Vis spectroscopy as a function of time. The as-prepared CuFe\textsubscript{2}O\textsubscript{4} nanoparticles, CuFe\textsubscript{2}O\textsubscript{4}/Ag nanoparticles, and CuFe\textsubscript{2}O\textsubscript{4}@COF nanocomposite were also applied for 4-NP reduction under the same conditions. For the catalyst recycling test, the catalyst was collected with an extra magnet after each cycle, and another 4-NP and NaBH\textsubscript{4} solution was added for the next catalytic cycle. The UV-Vis absorption of reaction solution was measured at 400 nm.

3. Results and Discussion

3.1. Fabrication and Characterization of CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF Nanocomposite

The magnetic CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF was synthesized by using CuFe\textsubscript{2}O\textsubscript{4}/Ag as a core, and TAPB-DMTP COF as a shell (Scheme 1). CuFe\textsubscript{2}O\textsubscript{4}/Ag was synthesized by depositing Ag on CuFe\textsubscript{2}O\textsubscript{4} nanoparticles, which was assisted by PDA reduction. This bi-catalyst composed of CuFe\textsubscript{2}O\textsubscript{4} and in situ synthesized Ag nanoparticles would accelerate the 4-NP reduction [34]. The COF shell encapsulation process was assisted by polyvinylpyrrolidone (PVP)-stabilized CuFe\textsubscript{2}O\textsubscript{4}/Ag strategy. This is because it has been proved that the amphiphilic PVP can stabilize the nanoparticles in the reaction solution and enhance the affinity between apolar groups of PVP and organic linkers [30]. At last, the TAPB-DMTP was assembled on the surface of CuFe\textsubscript{2}O\textsubscript{4}/Ag based on Schiff-base reaction to obtain the core-shell CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF nanocomposite [33].

![Scheme 1. Schematic representation of the synthesis of core-shell magnetic CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF nanocomposite.](image)

The core-shell structure and morphologies of the as-prepared CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF nanocomposite was verified by transmission electron microscopy (TEM) and scanning electron microscopy (SEM). Figure 1A and B revealed that the as-prepared CuFe\textsubscript{2}O\textsubscript{4}/Ag nanoparticles exhibited good monodispersity, and the CuFe\textsubscript{2}O\textsubscript{4} were spherical in shape with an average diameter of 200 nm. After being deposited with Ag nanoparticles, small Ag nanoparticles (~20 nm) were densely and uniformly assembled on the surface of CuFe\textsubscript{2}O\textsubscript{4}. After being coated with a COF layer, the COF shell (brighter) of TAPB-DMTP networks with a rough surface was formed and the thickness of ca. 30 nm surrounding the CuFe\textsubscript{2}O\textsubscript{4}/Ag core (darker) was clearly observed (Figure 1C). Meanwhile, at the edges of CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF spheres consisted of domains that contain regular channels along the radial direction (Figure S1). It is due to the self-assembly of the rod-like crystallites of the COF shell [35] and revealed a highly ordered porous structure of the CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF. Figure 1D displayed the high-resolution TEM images (HRTEM) and the corresponding fast Fourier transform (FFT) pattern of the CuFe\textsubscript{2}O\textsubscript{4}/Ag@COF nanocomposite. The spacing of the crystallographic plane of the Ag nanoparticles is 0.24 nm, which could be assigned to the (111) crystal planes of face-centered cubic (fcc) bulk Ag (0.235 nm). A clear inter-planar spacing of the lattice fringes is 0.25 nm, corresponding to the (311) crystal planes of CuFe\textsubscript{2}O\textsubscript{4} with cubic spinel structure.
Furthermore, the SEM image of CuFe₂O₄/Ag@COF also shows that the nanocomposite consisted of spheres with a rough and coarse surface (Figure 2A). The obtained nanocomposite is somewhat visibly sticky and exhibited convex domains due to the presence of porous TAPB-DMTP. To confirm the elemental composition of the CuFe₂O₄/Ag@COF, the EDX elemental mapping confirmed the presence of Cu, Fe, Ag, C, N, and O element (Figure 2B).

Fourier transform infrared (FTIR) spectroscopy was performed to confirm the successful preparation of the CuFe₂O₄/Ag@COF nanocomposite (Figure 3A). In the spectrum of CuFe₂O₄/Ag, the absorption broad band at 3430 cm⁻¹ represented the stretching mode of –OH groups and another peak at 1620 cm⁻¹ corresponded to the bending vibration of H₂O. In the lower zone, peak at 590 cm⁻¹
can be related to the vibration of the metal (tetrahedron)-oxygen (M–O), in which the atom M can be copper or iron. Another absorption peak at 428 cm\(^{-1}\) was referred to the vibration of octahedral sites of spinel-type oxide [36]. Compared with CuFeO\(_2\)/Ag, similar adsorption bands were observed in the spectrum of the as-prepared CuFeO\(_2\)/Ag@COF nanocomposite. New peaks at 1460 cm\(^{-1}\), 1501 cm\(^{-1}\) and 1405 cm\(^{-1}\) were assigned to the aromatic C–C ring stretch and methoxy group stretching the of TAPB-DMTP, respectively. Furthermore, the characteristic peaks at 3430 cm\(^{-1}\) and 1620 cm\(^{-1}\) became strong and sharp due to the existence of N–H bonds and C=N vibration of COF coating, validating the successful formation of COF shell via Shiff-base condensation reaction.

The crystallinity of CuFeO\(_2\)/Ag and CuFeO\(_2\)/Ag@COF was investigated by XRD measurements and the result was shown in Figure 3B. As shown in Figure 3B, the characteristic diffraction peaks at 2\(\theta\) = 30.2°, 35.5°, 43.4°, 57.3° and 62.6° corresponding to the (220), (311), (400), (511) and (440) crystal planes of CuFeO\(_2\) [36]. The pattern at 38.0°, 44.2° and 64.4° can be attributed to the (111), (200) and (220) crystalline planes of the synthesized Ag [37]. After the coating of TAPB-DMTP COF, the moderate new peaks at 2\(\theta\) = 5.60° and 7.4°, and weak peak at 9.7° belonging to the TAPB-DMTP was observed, which is consistent with that of TAPB-DMTP COF previously reported [29]. These results suggested that the CuFeO\(_2\)/Ag@COF nanocomposite exhibited the crystalline structure feature of magnetic CuFeO\(_2\)/Ag and TAPB-DMTP COF.

![Figure 3](image)

**Figure 3.** (A) Fourier transform infrared (FTIR) spectra of CuFeO\(_2\)/Ag and CuFeO\(_2\)/Ag@COF; (B) X-ray diffraction (XRD) patterns of CuFeO\(_2\)/Ag and CuFeO\(_2\)/Ag@COF.

TGA was further recorded to confirm the content of TAPB-DMTP coatings on the magnetic CuFeO\(_2\)/Ag (Figure 4A). As for CuFeO\(_2\)/Ag nanoparticles, a distinct weight-loss step of 1.7 wt% up to ca. 300 °C was observed, which can be attributed to the volatilization of the absorbed water and solvent molecule. Another sharply weight loss profile (5.0 wt%) in the range of 300–400 °C was observed due to the decomposition of PDA. Then it remained constant until the temperature rose to 800 °C, and demonstrated a remarkable thermo-stability of CuFeO\(_2\)/Ag. Compared with CuFeO\(_2\)/Ag, the CuFeO\(_2\)/Ag@COF nanocomposite had almost 14 wt% weight loss in the range of 400–700 °C, implying the decomposition of TAPB-DMTP and further demonstrated the presence of TAPB-DMTP COF shell. Meanwhile, the CuFeO\(_2\)/Ag@COF also exhibited excellent thermal stability in nitrogen up to 300 °C.

The pore structure of the CuFeO\(_2\)/Ag@COF was further evaluated by N\(_2\) adsorption-desorption at 77 K (Figure 4B). The isotherm of CuFeO\(_2\)/Ag presented a typical II characteristics, indicating the obviously non-porous structure of the solid sphere. Compared to CuFeO\(_2\)/Ag, a typical type IV isotherm was observed by CuFeO\(_2\)/Ag@COF, which is indicative of a mesoporous character. From pore size distribution curve (the inset of Figure 4B), the CuFeO\(_2\)/Ag@COF contained an average pore size of 3.15 nm with narrow sized distribution, which was well in agreement with theoretical value of the bulk COF (3.2 nm) [33]. In addition, the prepared CuFeO\(_2\)/Ag@COF gave an enhanced BET surface area and pore volume of 464.21 m\(^2\) g\(^{-1}\) and 0.396 m\(^3\) g\(^{-1}\) (38.60 m\(^3\) g\(^{-1}\) and 0.0862 m\(^3\) g\(^{-1}\) for
CuFeO$_2$/Ag), respectively (Table S1). The high external surface area with mesoporous structure indicates the superior concentration performance for the substrates, and thus made it possible for CuFeO$_2$/Ag@COF to facilitate efficient catalysis reduction of 4-NP.

![Figure 4](image)

**Figure 4.** (A) Thermogravimetric analysis (TGA) curves of CuFeO$_2$/Ag and CuFeO$_2$/Ag@COF (B) N$_2$ adsorption-desorption isotherms of CuFeO$_2$/Ag and CuFeO$_2$/Ag@COF (the inset shows pore size distribution of CuFeO$_2$/Ag@COF).

The vibrating sample magnetization (VSM) curves of CuFeO$_2$/Ag nanoparticle and CuFeO$_2$/Ag@COF nanocomposite are shown in Figure S2. All the materials obtained exhibited a superparamagnetic nature due to no obvious coercivity and remanence. After being assembled with TAPB-DMTP, the saturation magnetization of CuFeO$_2$/Ag@COF decreased from 62.7 emu g$^{-1}$ to 35.1 emu g$^{-1}$. However, very fast aggregation (about 1 min) of CuFeO$_2$/Ag@COF from the homogeneous dispersion was observed with the help of an extra magnet (as shown in the bottom-right inset of Figure S2).

To further analyze the chemical composition of the magnetic CuFeO$_2$/Ag@COF, XPS was carried out. In Figure 5A, the wide scan spectra of the magnetic CuFeO$_2$/Ag@COF displayed photoelectron lines at binding energies of 285, 402, and 528 eV, which can be assigned to C 1s, N 1s, and O 1s, respectively. The disappearing Fe, Cu, Ag peaks in the wide scan spectra indicating the inner CuFeO$_2$/Ag core was coated with a shell which was thicker than the analysis depth of XPS (~10 nm). The C 1s core-level photoelectron spectrum was split into three peaks located at 284.6, 286.3, and 290.8 eV, respectively (Figure 5B), which can be attributed to C–C/C=O, C–N, and C=N, respectively. The binding energies observed at Figure 5C showed the appearance of –NH– and –N= with their characteristic peaks at 398.4 and 400.0 eV. These results confirmed the successful formation of the COF shell.
3.2. Catalytic Reduction of 4-NP

The as-prepared CuFeO$_2$O$_4$/Ag@COF nanocomposite has advantages of large surface area, rapid magnetic response, abundant catalytic sites, which can make sure the high catalytic performance and the catalyst stability towards 4-NP reduction. The catalytic performance of CuFeO$_2$O$_4$/Ag@COF was tested for reducing 4-NP in the presence of excess NaBH$_4$ in water. The reaction kinetics were monitored by UV-vis absorption spectroscopy of the reaction mixture after adding the catalyst. Notably, the absorption peak of 4-nitrophenol shifts from 319 to 400 nm (the aqueous solution turns from light yellow to bright yellow rapidly) after adding NaBH$_4$ due to the formation of 4-nitrophenolate ions in the alkaline medium.

Figure 6A and B showed the successive UV-vis spectra of 4-nitrophenolate catalyzed by CuFeO$_2$O$_4$/Ag and CuFeO$_2$O$_4$/Ag@COF in the presence of NaBH$_4$, respectively. The absorption peak at 400 nm was observed to decrease in intensity and a new peak at ~300 nm increased along with the reaction time, suggesting the reduction of 4-NP to give 4-AP as the sole product [38]. Figure 6A shown that the catalytic reduction with CuFeO$_2$O$_4$/Ag nanoparticles could be completed within 11 min. When CuFeO$_2$O$_4$/Ag@COF was used as the catalyst (Figure 6B), a significant catalytic activity was observed and conversion of 4-NP to 4-AP was finished within 4 min. We can speculate that the momentous activity shown by CuFeO$_2$O$_4$/Ag@COF over CuFeO$_2$O$_4$/Ag own to the porous COF matrix, which provided a large surface area of the encapsulated CuFeO$_2$O$_4$/Ag nanoparticles and high particle number per unit mass for the catalyst. The increased fraction of the substrates at the surface of CuFeO$_2$O$_4$/Ag@COF led to a significantly higher catalytic activity.
Since the concentration of BH₄⁻ added in the system is in excess compared to the concentration of 4-NP, pseudo-first-order kinetics is expected for the catalytic reaction under this circumstance (Figure 6C). The pseudo-first-order kinetics can be described as:

$$\ln\left(\frac{C_t}{C_0}\right) = -kt$$

where $C_t$ is the concentration of 4-NP at time $t$, $C_0$ is the initial concentration of 4-NP, and $k$ is the rate constant. From Figure 6C we can see all composite samples can catalyze 4-NP reduction but display different activities. Basically, single-catalyst showed lower catalytic activity than the dual-catalyst. For example, CuFe₂O₄@COF had a decreased catalytic activity (with the rate constant of 0.15 min⁻¹) and much lower activity for CuFe₃O₄ (with the rate constant of 0.08 min⁻¹), respectively, in comparison with that of CuFe₂O₄/Ag (0.25 min⁻¹). Moreover, when dual-catalyst was applied, the catalytic performances of the resulting catalysts were inherently influenced by the crystal COF shell. For example, CuFe₂O₄/Ag@COF displayed a higher catalytic activity (with the rate constant of 0.77 min⁻¹) than that of CuFe₂O₄/Ag. Specifically, CuFe₂O₄/Ag@COF exhibited the highest activity, which was 3, 5 and 10 times higher than that of CuFe₂O₄/Ag, CuFe₂O₄@COF and CuFe₃O₄, respectively. It can be assumed that the sluggish reaction kinetics of the above three kinds of catalysts (CuFe₂O₄/Ag, CuFe₂O₄@COF and CuFe₃O₄) highlighted the utility of the dual-catalyst and ordered mesoporous COF shell. This result also showed superior catalytic activity compared to the composite of noble metals (such as Ag, Pd, and Au nanoparticles) embedded in other porous matrix tested under the similar conditions (Table S2).

Additionally, the reusability of CuFe₂O₄/Ag@COF was further displayed. With high saturation magnetization, the CuFe₂O₄/Ag@COF can be easily separated in a few seconds using an external magnetic field. Figure 6D displayed the conversion for the reduction of 4-NP in an estimated time span of 4 min. The result displayed excellent reusability of the catalyst for more than 6 catalytic cycles with yields over 95%, indicating excellent reusability and stability towards the as-prepared CuFe₂O₄/Ag@COF nanocomposite. The slightly decreased conversions in the later catalysis cycles are presumably caused by the loss of catalyst during the washing process between cycles. The SEM image manifested that the structure of the recycled CuFe₂O₄/Ag@COF was preserved and no obvious aggregation was observed, further confirming the excellent stability of the prepared catalyst (Figure S3). Hence, the prominent catalytic activity and high stability of CuFe₂O₄/Ag@COF can be attributed to the highly stable mesoporous architecture (TAPB-DMTP), which held the encapsulated nanoparticles to a high extent and provided docking sites for 4-NP.
Figure 6. (A) Typical time-dependent evolution of ultraviolet-visible (UV-Vis) spectra for the catalytic reduction of 4-nitrophenol (4-NP) to p-aminophenol (4-AP) by CuFeO₄/Ag; (B) typical time-dependent evolution of UV-Vis spectra for the catalytic reduction of 4-NP to 4-AP by CuFeO₄/Ag@COF; (C) relationship of the ln[4-NP] and the reaction time t for the reduction of 4-NP to 4-AP over CuFeO₄, CuFeO₄@COF, CuFeO₄/Ag and CuFeO₄/Ag@COF; (D) the reusability of CuFeO₄/Ag@COF for the reduction of 4-NP by NaBH₄.

3.3. Plausible Mechanisms

Scheme 2 depicts the performance of CuFeO₄/Ag@COF as catalyst in reducing 4-NP to 4-AP by NaBH₄. In aqueous medium, NaBH₄ was first diffused through the mesoporous COF shell and adhered onto the surface of CuFeO₄/Ag, then electrons transferred from CuFeO₄/Ag to the adsorbed BH₄⁻ with hydride ions’ production. Simultaneously, the 4-NP were adsorbed onto the mesoporous COF shell via π-π stacking interactions because 4-NP is π-rich in nature [38]. Subsequently, the hydrogen atom formed from the hydride ions attacked 4-NP molecules to reduce them based on electron transfer to the CuFeO₄/Ag nanoparticles, forming the product 4-AP [38]. The surface of dual-catalyst CuFeO₄/Ag is presumed to play a role in electrically connecting two adsorbates through the surface so that electrons can be transferred from the oxidation site (NaBH₄) to the reduction site (4-NP). Such preconcentration of BH₄⁻ and 4-NP in the COF shell would result in more frequent contact of the inner CuFeO₄/Ag catalyst with reactants, thereby facilitating a highly efficient catalysis. Moreover, it has been revealed that CuFeO₄ with ‘dⁿ’ (n = 5–9) electronic configuration exhibited better catalytic activity for reduction of nitrophenol [30]. Specifically, both Cu²⁺ and Fe³⁺ ions present in the octahedral sites exposed on the surface of particles, thus the reduction of hydride ions would be accelerated by the enhanced electron transfer boosted by Ag and neighboring CuFeO₄ nanoparticles (Scheme 2).
Scheme 2. The mechanism of the reduction of 4-NP to 4-AP by NaBH₄ in the presence of CuFe₂O₄/Ag@COF.

4. Conclusions

In summary, we have presented a facile and efficient strategy to construct core-shell magnetic CuFe₂O₄/Ag@COF nanocomposite. The obtained nanocomposite not only retained its high crystallinity, large surface area and thermal stability of the COF shell, but held high catalytic properties and strong magnetic effect of magnetic CuFe₂O₄/Ag nanoparticles. By virtue of these merits, the CuFe₂O₄/Ag@COF exhibited enhanced catalytic activity, robust recyclability and stability for the catalytic reduction of 4-NP by NaBH₄. Specifically, the apparent reaction rate of CuFe₂O₄/Ag@COF was 3 times higher than that by CuFe₂O₄/Ag, which can be ascribed to the enhanced CuFe₂O₄/Ag dispersion and the strengthened interfacial interaction. Moreover, the magnetic CuFe₂O₄/Ag@COF can be recycled easily by a magnet and exhibited robust reusability for six cycles with minimal loss of catalytic activity but held its structural integrity. Encouraged by the effective catalysis of 4-NP with this nanocomposite, it can be expected that the rational design of the promising catalytic material with magnetic platforms and a tunable porous COF shell will be developed and applied for many redox-active environmental contaminants.

Supplementary Materials: The following are available online at www.mdpi.com/xxx/s1: Figure S1: TEM image of the CuFe₂O₄/Ag@COF, Figure S2: Magnetic hysteresis loops of CuFe₂O₄/Ag and CuFe₂O₄/Ag@COF (the inset shows the magnetic separation behavior of CuFe₂O₄/Ag@COF in aqueous solution), Figure S3: SEM image of the recycled CuFe₂O₄/Ag@COF after six times reuse, Table S1: Nitrogen adsorption-desorption data of CuFe₂O₄/Ag and CuFe₂O₄/Ag@COF, Table S2: Comparison of k value of different catalytic systems for the reduction of 4-NP (298K).

Author Contributions: Conceptualization, C.H. and D.Z.; data curation, D.Z., W.C., and H.L.; formal analysis, D.Z., W.C., and H.L.; methodology, C.H. and D.Z.; software, C.H. and D.Z.; writing—original draft preparation, C.H. and D.Z.; writing—review and editing, C.H. All authors have read and agreed to the published version of the manuscript.

Funding: This work was supported by the Guangxi Key Laboratory of Clean Pulping, Papermaking and Pollution Control Opening Fund (KF 201711), and the Open Project Program of National Demonstration Center for Experimental Light Chemistry Engineering Education (Grant No. 2018QGSJ02-09), Shaanxi University of Science and Technology, and the Key Scientific Research Plan of Shaanxi Provincial Education Department (No.17JJS016).
