Abstract—This paper aims to characterize the synergy of distributed caching and wireless fronthaul in a fog radio access network (Fog-RAN) where all edge nodes (ENs) and user equipments (UEs) have a local cache and store contents independently at random. The network operates in two phases, a file-splitting based decentralized cache placement phase and a fronthaul-aided content delivery phase. We adopt normalized delivery time (NDT) to characterize the asymptotic latency performance with respect to cache size and fronthaul capacity. Both an achievable upper bound and a theoretical lower bound of NDT are obtained, and their multiplicative gap is within 12. In the proposed delivery scheme, we utilize the fronthaul link, by exploiting coded multicasting, to fetch both non-cached and cached contents to boost EN cooperation in the access link. In particular, to fetch contents already cached at ENs, an additional layer of coded multicasting is added on the coded messages desired by UEs in the fronthaul link. Our analysis shows that the proposed delivery scheme can balance the delivery latency between the fronthaul link and access link, and is approximately optimum under decentralized caching.

I. INTRODUCTION

Caching is emerging as an effective technique to reduce peak-hour data traffic and improve user perceived experience in wireless networks. Unlike traditional web-caching and in-network caching, caching at the edge of wireless networks is able to exploit the broadcast nature of wireless medium and thus achieve global caching gain. Recently, it has attracted many interests to characterize the fundamental limits of caching in various wireless networks. This work aims to advance this topic by studying the synergy between distributed caching and wireless fronthauling in fog radio access networks (Fog-RANs).

Previously, the gain of caching is studied in wireless interference networks where caches are equipped at all transmitters and receivers. It is found that with a generic file splitting and caching strategy, the interference network topology can be changed into a new family of channels, referred to as cooperative X-multicast channels, and hence leverage transmitter cooperation gain and coded multicasting gain, apart from receiver local caching gain. These works, however, have assumed that there exists a central controller that coordinates the file splitting and cache placement among all distributed nodes (at least all the transmit nodes if not receive nodes as in ). Moreover, they also assume that the total cache size among the network nodes is large enough to collectively store the entire database without cache miss.

To exploit the potential of practical and scalable caching in large and random networks, decentralized coded caching is proposed at the user side where users can independently cache file bits at random. It is shown that decentralized coded caching can achieve a performance close to the optimal centralized scheme.

The idea of decentralized coded caching can be extended to a general interference network where all the transmitters and receivers cache file bits independently at random. However, due to the lack of a central controller for careful cache placement, it is very likely to have cache miss even when the total cache size is as large as in the centralized scheme. To overcome the cache miss issue, the works consider a Fog-RAN where each cache-enabled edge node (EN) is connected via a fronthaul link to a cloud server which has access to the entire database. They characterize a latency-oriented performance with respect to both the EN cache size and the fronthaul capacity. The works consider a Fog-RAN where all ENs and user equipments (UEs) are equipped with local caches. The authors in propose a caching-and-delivery scheme that combines network-coded fronthaul transmission and cache-aided interference management. The authors in propose a mixed cache placement, i.e., centralized caching at ENs and decentralized caching at UEs, and employ a combination of interference management techniques in the delivery phase. The authors in consider a decentralized cache placement at all ENs and UEs and propose a coded delivery strategy that exploits the network topology for Fog-RANs. Note that is only limited to two ENs only.

The contribution of this work is to characterize the latency performance of a Fog-RAN with wireless fronthaul and for arbitrary number of ENs and UEs, where all ENs and UEs are equipped with caches. Considering the random mobility of UEs and the dynamic on/off of ENs, we apply decentralized cache placement at all ENs and UEs without central coordination. As in , , , , , we adopt normalized delivery time (NDT) as the performance metric. The network operates in two phases, a decentralized cache placement phase
and a fronthaul-aided content delivery phase. In our proposed delivery scheme, the wireless fronthaul is not only responsible to fetch cache-miss contents but also can be used to fetch contents already cached at ENs to boost transmission cooperation to any desired level in the access link. To fetch contents already cached at ENs, an additional layer of coded multicasting on top of the coded messages desired by UEs is exploited in the fronthaul link. To fetch contents not cached at ENs, the coded messages, rather than the original files desired by UEs, are transmitted in the fronthaul link. The access transmission in our proposed delivery scheme is similar to [2], which transforms the access link into the cooperative X-multicast channel. Based on the proposed delivery scheme, we obtain an achievable upper bound of the minimum NDT.

The communication at each time slot $t$ experiences channel fading and additive white Gaussian noise. The channel is modeled by

$$Y_q(t) = \sum_{p=1}^{N_T} h_{qp}(t)X_p(t) + Z_q(t), q \in [N_R],$$

where $Y_q(t) \in \mathbb{C}$ is the received signal at UE $q$, $X_p(t) \in \mathbb{C}$ is the transmitted signal at EN $p$, $h_{qp}(t) \in \mathbb{C}$ is the channel coefficient from EN $p$ to UE $q$ which is assumed to be independent and identically distributed (i.i.d.) as some continuous distribution, and $Z_q(t)$ is the noise at UE $q$ distributed as $CN(0,1)$.

The fronthaul link between the MBS and all the ENs also experiences channel fading and additive white Gaussian noise. The communication at each time slot $t$ over the fronthaul channel is modeled by

$$Q_p(t) = g_p(t)S(t) + N_p(t), p \in [N_T],$$

where $Q_p(t) \in \mathbb{C}$ is the received signal at EN $p$, $S(t) \in \mathbb{C}$ is the transmitted signal from the MBS, $g_p(t) \in \mathbb{C}$ is the channel coefficient from the MBS to EN $p$ which is assumed to be i.i.d. as some continuous distribution, and $N_p(t)$ is the noise at EN $p$ distributed as $CN(0,1)$.

Consider a database consisting of $N$ files, denoted as $\{W_1, W_2, \ldots, W_N\}$, each with $F$ bits. Throughout this study, we consider $N \geq N_R$ so that each UE can request a distinct file. The MBS has full access to the database via a dedicated backhaul link. Each EN can store $\mu_T N_F$ ($\mu_T \leq 1$) bits locally, and each UE can store $\mu_R N_F$ ($\mu_R \leq 1$) bits locally, where $\mu_T$ and $\mu_R$ are referred to as normalized cache sizes at each EN and UE, respectively. In this work, we consider the complete region for the normalized cache sizes, i.e., $0 \leq \mu_R, \mu_T \leq 1$, because of the presence of the fronthaul. Note that the works [2, 5] only consider the feasible region $\mu_T \mu_T + \mu_R \geq 1$, while [3, 4] only consider $\mu_T \mu_T \geq 1$.

The network operates in two phases, a decentralized cache placement phase and a two-hop content delivery phase, as detailed in the next two subsections.

B. Decentralized Cache Placement

We adopt decentralized cache placement at all ENs and UEs. Each EN $p$ (or UE $q$) independently caches a subset of $\mu_T F$ (or $\mu_F$) bits of each file $W_n$, chosen uniformly at random, denoted as $U^n_p$ (or $V^n_q$), for $n \in [N]$. Denote $U^n_p = \bigcup_{q \in [N]} U^n_q$ (or $V^n_q = \bigcup_{n \in [N]} V^n_q$) as all the cached bits at EN $p$ (or UE $q$). Note that neither inter-file nor intra-file coding is allowed in the considered decentralized cache placement phase.

By the law of large numbers, when file size $F$ is large enough, the size of each subfile cached exactly at an arbitrary set of $m$ UEs ($0 \leq m \leq N_R$) and an arbitrary set of $n$ ENs ($0 \leq n \leq N_T$) is $\mu_R \mu_T (1 - \mu_R) N_R - m \mu_T (1 - \mu_T) N_T - n F + o(F)$ bits with high probability. Since this paper focuses on the extreme case when $F \to \infty$, we ignore the $o(F)$ term in the rest of the paper, and define

$$f_{m,n} \triangleq \mu_R \mu_T (1 - \mu_R) N_R - m \mu_T (1 - \mu_T) N_T - n F$$

as the fractional size of each subfile cached exactly at each node set with $m$ UEs and $n$ ENs, similar to [6].

C. Two-Hop Content Delivery

Each UE $q$ requests a file $W_{d_q}$ from the database. We denote $d_q = (d_{q,n})_{n=1}^{N_R}$ as the demand vector from all the $N_R$ UEs. The content delivery phase is a two-hop transmission process, the first hop being the fronthaul channel and the second hop being the access channel.
1) **Fronthaul Transmission:** The MBS employs an encoding function \( \Lambda_C \) to map the entire database, UE demand \( \mathbf{d} \), and channel realization \( \mathbf{G}_F \) to a length-\( T_F \) codeword \( \{ \mathbf{S}[t] : \forall t \in [N_T], \forall t \in [T_F] \} \) with an average transmit power constraint \( P_r \), i.e., \( \frac{1}{T_F} \sum_{t=1}^{T_F} |\mathbf{S}(t)|^2 \leq P_r \), where \( r > 0 \) is the power scaling of the fronthaul link compared to the access link with power \( P \). Note that \( r \) can also be viewed as the multiplexing gain in the fronthaul link \([11]\).

2) **Access Transmission:** In this paper, we assume that all the ENs are half-duplex, which means that they cannot transmit over the access link while receiving from the fronthaul link at the same time. Thus, the fronthaul transmission and the access transmission take place in serial. After receiving signals from the fronthaul link, each EN \( p \) uses an encoding function \( \Lambda_p \) to map its cached content \( U_p \), UE demand \( \mathbf{d} \), received signals \( \{ \mathbf{Q}_q[t] : \forall t \in [T_A] \} \), and channel realizations \( \mathbf{G}_F \) and \( \mathbf{H}_A \) to a length-\( T_A \) codeword \( \{ \mathbf{X}_q[t] : \forall t \in [T_A] \} \). Note that \( T_F \) and \( T_A \) may depend on the UE demand \( \mathbf{d} \) and channel realizations \( \mathbf{G}_F \) and \( \mathbf{H}_A \). Each code word \( \{ \mathbf{X}_q[t] : \forall t \in [T_A] \} \) has an average transmit power constraint \( P_r \), i.e., \( \frac{1}{T_A} \sum_{t=1}^{T_A} |\mathbf{X}(t)|^2 \leq P_r \).

Upon receiving signals \( \{ \mathbf{Y}_q[t] : \forall t \in [T_A] \} \) in the access link, each UE \( q \) employs a decoding function \( \Gamma_q \) to decode \( W_{d_q} \) of its desired file \( W_{d_q} \) from \( \{ \mathbf{Y}_q[t] : \forall t \in [T_A] \} \) along with its cached content \( V_q \), UE demand \( \mathbf{d} \), and channel realizations \( \mathbf{G}_F \) and \( \mathbf{H}_A \) as side information.

Define \( P_r \equiv \max_{q} \max_{p} \max_{\mathbf{d}} \mathbb{P}(W_{d_q} \neq W_{d_q}) \) as the worst-case error probability. A given set of coding functions \( \{ \Lambda_C, \Lambda_p, \Gamma_q : p \in [N_T], q \in [N_R] \} \) in the delivery phase is said to be feasible if, for almost all channel realizations, \( P_r \rightarrow 0 \) when \( F \rightarrow \infty \).

### D. Performance Metric

Following \([7]\), we adopt normalized delivery time (NDT) as the performance metric which is given by

\[
\tau(\mu_R, \mu_T, r) \triangleq \lim_{F \to \infty} \lim_{r \to \infty} \sup_{P} \frac{\max_{q} (T_F + T_A)}{F / \log P}.
\]

We are interested in characterizing the minimum NDT of the network with decentralized caching which is defined as \( \tau^* (\mu_R, \mu_T, r) = \inf \{ \tau(\mu_R, \mu_T, r) : \tau(\mu_R, \mu_T, r) \} \) is achievable.

**Remark 1.** Similar to \([9]\), given the two-hop content delivery phase, the NDT can be rewritten as \( \tau = \tau_F + \tau_A \), where \( \tau_F \) and \( \tau_A \) is the NDT in the fronthaul link and access link, respectively. Based on the power constraint of fronthaul codeword \( \{ \mathbf{S}[t] : \forall t \in [T_F] \} \), the fronthaul link carries \( r \log P \) bits per channel use in the high SNR regime. Denote \( R_F \) as the sum traffic load normalized by file size \( F \) in the fronthaul link. We can rewrite \( \tau_F \) as \( \tau_F = R_F / r \). Similar to \([2]\) Remark 1, denote \( R_A \) as the per-user traffic load normalized by file size \( F \) and \( d \) as the per-user degrees of freedom (DoF) in the access link. We can rewrite \( \tau_A \) as \( \tau_A = R_A / d \). Therefore, the NDT can be expressed more conveniently as

\[
\tau = \tau_F + \tau_A = R_F / r + R_A / d.
\]

1 The same metric is also defined in \([12]\) but under a different name.

### III. Delivery Scheme for 3 \( \times \) 3 Fog-RAN

In this section, we use a Fog-RAN with \( N_T = N_R = 3 \) to illustrate the proposed delivery scheme. The scheme can be easily generated to a general Fog-RAN with arbitrary \( N_T \) and arbitrary \( N_R \), which is given in Section IV. We consider the worst-case scenario that each UE requests a distinct file. Note that when some UEs request the same file, the proposed delivery scheme can still be applied by treating the requests as being different. Without loss of generality, we assume that UE \( q \) desires \( W_q \), for \( q \in [3] \). We denote \( W_q, q, \Phi \), as the subfile desired by UE \( q \) and cached at UE set \( \Phi_q \). The fractional size is given by \( f_{\Phi_q, \Phi} = \mu_{\Phi_q} (1 - \mu_{\Phi_q})^{3 - |\Phi_q|} (1 - \mu_{\Phi})^{3 - |\Phi|} \) based on \([1]\).

Excluding the locally cached subfiles, each UE \( q \), for \( q \in [3] \), wants subfiles \( \{ W_q, q, \Phi : \Phi \neq q, \Phi \subseteq [3], \Psi \subseteq [3] \} \). We divide the subfiles wanted by all UEs into different groups according to the size of \( \Phi_q \), \( \Psi \), and \( \Phi \), indexed by \( \{ (m, n) : m \in [2] \cup \{0\}, n \in [3] \cup \{0\} \} \), such that subfiles in group \((m, n)\) are cached at all UEs from \( m \) ENs, and \( n \) ENs. There are \( 3(\frac{2}{m})^{(3)} \) subfiles in group \((m, n)\). Each group of subfiles is delivered individually in the time division manner. In the following, we present the delivery strategy of two representative groups, \((m, 0)\) and \((m, 1)\), where \( m \in [2] \cup \{0\} \). Before that, let us introduce the cooperative X-multicast channel defined in \([2]\) Definition 2 which shall be mentioned throughout this section and Section IV.

**Definition 1 (\([2]\)).** The channel characterized as follows is referred to as the \((N_T) \times (N_R + 1)\) cooperative X-multicast channel:

1) there are \( N_R \) UEs and \( N_T \) ENs;
2) each set of \( m + 1 \) \( (m < N_R) \) UEs forms a UE multicast group;
3) each set of \( j \) \( (j \leq N_T) \) ENs forms a EN cooperation group;
4) each EN cooperation group has an independent message for each UE multicast group.

#### A. Delivery of Group \((m, 0)\)

Each subfile in group \((m, 0)\) is desired by one UE, cached at \( m \) other UEs but none of ENs. Coded multicasting can be exploited through bit-wise XOR, similar to \([1]\). In specific, the set of coded messages is given by

\[
W_{\Phi +, \emptyset} \triangleq \bigoplus_{q \in \Phi} W_q | q \subseteq [3], |\Phi^+| = m + 1 \bigcup \emptyset.
\]

In this work, we focus on the case with \( F \to \infty \) for analytical tractability. By the law of large numbers, each coded message \( W_{\Phi +, \emptyset} \) has \( f_{m, n} F \) bits, and is desired by UE set \( \Phi^+ \). Since the ENs do not have the coded messages in \([3]\), these messages need to be generated at the MBS and then delivered to UEs via two compulsory hops, the fronthaul link and the access link. In the fronthaul link, we let the MBS naively multicast...
each coded message in (4) one by one to all three ENs. Thus, from Remark 1 the NDT of the fronthaul link is given by
\[ \tau_F = \left( \frac{3}{m+1} \right) f_{m,0} \cdot \frac{1}{r}. \] (5)

By such naive multicasting in the fronthaul link, each EN now has access to all the coded messages in (4), and can transmit with full cooperation in the access link. The access channel thus becomes the \( \left( \frac{3}{m+1} \right) \times \left( \frac{3}{m+1} \right) \) cooperative X-multicast channel in Definition 1 whose achievable per-user DoF is \( d_{m,3} = 1 \) in [2] Lemma 1. Since each UE desires \( m \) coded messages, from Remark 1 the NDT of the access link is given by
\[ \tau_A = \left( \frac{2}{m} \right) f_{m,0} \cdot \frac{1}{d_{m,3}}. \] (6)

Summing up (5) and (6), the total NDT for group \((m, 0)\) is
\[ \tau_{m,0} = \left( \frac{3}{m+1} \right) f_{m,0} + \left( \frac{2}{m} \right) f_{m,0}. \]

B. Delivery of Group \((m, 1)\)

Unlike the subfiles in group \((m, 0)\), each subfile in group \((m, 1)\) is already cached at one EN, and therefore the coded messages can be generated at each EN locally. In specific, each EN \( p \), for \( p \in [3] \), generates:
\[ \left\{ W_{\Phi^+, (p)}^i : \Phi^+ \subseteq [3], |\Phi^+| = m+1 \right\}. \] (7)

Each coded message \( W_{\Phi^+,(p)}^i \) has \( f_{m,1} \) bits, and is desired by UE set \( \Psi^+ \). These coded messages can be delivered to UEs via one hop in the access link without the use of fronthaul link or delivered via two hops with the aid of fronthaul link.

1) Without Fronthaul: Each EN \( p \), for \( p \in [3] \), sends \( \left\{ W_{\Phi^+, (p)}^i \right\} \) in the access link, and the access channel becomes the \( \left( \frac{3}{m+1} \right) \times \left( \frac{3}{m+1} \right) \) cooperative X-multicast channel with achievable per-user DoF \( d_{m,1,i} \) in [2] Lemma 1. Since each UE desires \( 3 \left( \frac{3}{m} \right) \) messages, the NDT is given by
\[ \tau = \left( \frac{3}{m+1} \right) f_{m,1}. \] (8)

2) With Fronthaul: With the aid of fronthaul, we can allow ENs to access the coded messages of others via the transmission of the MBS in the fronthaul link, thereby enabling transmission cooperation among ENs in the access link. As a price to pay for the EN cooperation gain, additional fronthaul delivery latency is caused. Thus, the optimal cooperation strategy should balance the time between the access link and the fronthaul link.

Assume that after the aid of fronthaul transmission, every set of \( 1+i \) ENs can form a cooperation group in the access link, where \( i \) is a design parameter to balance the tradeoff mentioned above. We split each message \( W_{\Phi^+,(p)}^i \) in (7) into \( \left( \frac{3}{i} \right) \) sub-messages \( \left\{ W_{\Phi^+, (p)}^i : \Phi^+ \subseteq [3], |\Phi^+| = 1+i, \Phi^+ \ni p \right\} \), each with \( f_{m,1}/\left( \frac{3}{i} \right) \) bits and sent by EN set \( \Psi^+ \) exclusively in the access transmission. Consider an arbitrary EN set \( \Psi^+ \) with size \( 1+i \), ENs in \( \Psi^+ \) need to send sub-messages
\[ \left\{ W_{\Phi^+, (p)}^i : \Phi^+ \subseteq [3], |\Phi^+| = m+1, p \in \Psi^+ \right\} \] (9)
to UEs, and the MBS needs to send \( W_{\Phi^+, (p')}^i \) to ENs \( \{ p' : p' \in \Psi^+ \backslash \{p\} \} \) which do not cache it. Given that each sub-message is already cached at one EN, coded multicasting can be used in the fronthaul transmission. In specific, the MBS sends coded sub-messages
\[ \left\{ W_{\Phi^+, (p)}^i \oplus W_{\Phi^+, (p')}^i : \Phi^+ \subseteq [3], |\Phi^+| = m+1, p, p' \in \Psi^+ \right\} \]
to EN set \( \Psi^+ \). Note that in (9), the MBS sends coded messages generated directly from sub-files \( \left\{ W_{\Phi^+, (p)}^i \right\} \) to ENs, not from the coded messages in (9). Compared to (9), an additional layer of XOR combining on top of the coded messages desired by UEs is exploited in our scheme. Upon receiving the above coded sub-messages, each EN in \( \Psi^+ \) can decode its desired sub-messages with its local cache. The fronthaul NDT for the given \( i \) is thus given by
\[ \tau_F = \left( \frac{3}{m+1} \right) \left( \frac{3}{i+1} \right) f_{m,1} \cdot \frac{1}{r}. \] (10)

By such coded multicasting in the fronthaul link, each EN set \( \Psi^+ \) with size \( 1+i \) can cooperatively send sub-messages in (9), each desired by \( m+1 \) UEs. The network in the access transmission is upgraded into the \( \left( \frac{3}{i+1} \right) \times \left( \frac{3}{m+1} \right) \) cooperative X-multicast channel with achievable per-user DoF \( d_{m,1,i+1} \) in [2] Lemma 1. Since each UE wants \( \left( \frac{3}{i+1} \right) \left( \frac{3}{m+i+1} \right) \) sub-messages, each with \( f_{m,1}/\left( \frac{3}{i+1} \right) \) bits, the access NDT is
\[ \tau_A = \left( \frac{3}{m+1} \right) \left( \frac{3}{i+1} \right) f_{m,1} \cdot \frac{1}{d_{m,1,i+1}}. \] (11)

Summing up (10) and (11), the total NDT is given by
\[ \tau = \left( \frac{3}{m+1} \right) i f_{m,1} + \left( \frac{3}{m+1} \right) f_{m,1} \cdot \frac{1}{d_{m,1,i+1}}. \] (12)

Choosing the smallest NDT among (8) without fronthaul delivery and (12) with fronthaul delivery for all possible \( i \), we obtain the NDT for group \((m, 1)\) as
\[ \tau_{m,1} = \min_{i \in [2]:i \not\in [0]} \left\{ \left( \frac{3}{m+1} \right) i f_{m,1} + \left( \frac{3}{m+1} \right) f_{m,1} \cdot \frac{1}{d_{m,1,i+1}} \right\}. \]

Considering all possible \( m \) and \( n \), the achievable NDT of the \( 3 \times 3 \) Fog-RAN with decentralized caching is
\[ \sum_{m=0}^{\infty} \sum_{n=0}^{\infty} \tau_{m,n}, \text{ where } \tau_{m,n} \text{ is the NDT for group } (m, n). \]

IV. ACHIEVABLE UPPER BOUND OF NDT

Generalizing the achievable scheme in Section III to arbitrary \( N_T, N_R \geq 2 \), we obtain an achievable upper bound of the minimum NDT in the Fog-RAN with decentralized cache placement in the following theorem.

**Theorem 1 (Achievable NDT).** For the cache-aided Fog-RAN with \( N_T \geq 2 \) ENs, each with a cache of normalized size \( \mu_T \), \( N_R \geq 2 \) UEs, each with a cache of normalized size \( \mu_R \), \( N \geq N_R \) files, and a wireless fronthaul link with power scaling
For access link. In the fronthaul link, we let the MBS multicast MBS and then delivered to UEs via the fronthaul link and the fronthaul NDT is given by

$$\tau_{m,0} = \frac{N_m f_{m,0}}{r} + \frac{(N_m-1) f_{m,0}}{d_{m,N_T}}. \quad (13)$$

Combining (17) and (18), the achievable NDT for the delivery of group \((m,0)\) is

$$\tau_{m,0} = \frac{(N_m f_{m,0})}{r} + \frac{(N_m-1) f_{m,0}}{d_{m,N_T}}. \quad (19)$$

Proof. Similar to Section III, we assume that UE \(q\) for \(q \in [N_R]\), desires \(W_q\) in the delivery phase. Excluding the locally cached subfiles, each UE \(q\) for \(q \in [N_R]\), wants subfiles \(\bigcup_{\Phi \neq q, \Phi' \subseteq [N_R], q \notin [N_R]} W_{q,\Phi \setminus \{q\}, \Phi'}\). We divide the subfiles wanted by all UEs into different groups according to the size of \(\Phi\) and \(\Psi\), indexed by \(\{(m,n) : 0 \leq m \leq N_R - 1, 0 \leq n \leq N_T, m,n \in \mathbb{Z}\}\), such that subfiles in group \((m,n)\) are cached at \(m\) UEs and \(n\) ENs. There are \(N_R(N_R-1)(N_R+1)\) subfiles in group \((m,n)\), each with fractional size \(f_{m,n}\). Each group of subfiles is delivered individually in the time division manner. Without loss of generality, we present the delivery strategy for an arbitrary group \((m,n)\). The delivery strategy is also given in Algorithm 1.

1) \(n = 0\): Note that each subfile in group \((m,0)\) is desired by one UE, and already cached at \(m\) different UEs but none of ENs. Coded multicasting approach can be used, similar to Section III-A. In specific, the coded messages are given by

$$\mathcal{W}^{\oplus}_{\Phi^+, \Phi^-} = \bigoplus_{\Phi' \subseteq \Phi^+} \mathbb{W}_{q, \Phi' \setminus \{q\}, \Phi'}, \Phi' \subseteq [N_R], |\Phi'| = m + 1, \ \Phi \subseteq [N_R].$$

(16)

Each coded message \(\mathcal{W}^{\oplus}_{\Phi^+, \Phi^-}\) is desired by UE set \(\Phi^+\). (If \(m = 0\), each coded message \(\mathcal{W}^{\oplus}_{\Phi^+, \Phi^-}\) degenerates to subfile \(W_{q, \Phi^+, \Phi^-}\) for \(\Phi^+ = \{q\}\).) These messages need to be generated at the MBS and then delivered to UEs via the fronthaul link and the access link. In the fronthaul link, we let the MBS multicast each coded message in (16) to all the \(N_T\) ENs one by one. The fronthaul NDT is given by

$$\tau_F = \frac{(N_R f_{m,0})}{r}.$$ (17)

By such naive multicast transmission in the fronthaul link, each EN now has access to all the coded messages in (16), and can cooperatively transmit together in the access link. The access channel thus becomes the \((N_T R) \times \binom{N_R}{m+1}\) cooperative X-multicast channel with achievable per-user DoF \(d_{m,N_T}\) in [2] Lemma 1. Since each UE desires \((N_R-1)\) messages, the access NDT is given by

$$\tau_A = \frac{(N_m f_{m,0})}{d_{m,N_T}}. \quad (18)$$

Algorithm 1 Delivery scheme for \(N_T \times N_R\) Fog-RAN with wireless fronthaul

1. for \(m = 0, 1, \ldots, N_R - 1\) do
2. for \(n = 0, 1, \ldots, N_T - 1\) do
3. if \(n = 0\) then
4. Generate coded messages \(\bigoplus_{\Phi \subseteq [N_R], |\Phi'| = m + 1} W_{q, \Phi^+, \Phi^-} \subseteq [N_R], |\Phi'| = m + 1\) to all the \(N_T\) ENs one by one
5. The MBS sends messages \(\bigoplus_{\Phi \subseteq [N_R], |\Phi'| = m + 1} W_{q, \Phi^+, \Phi^-}\) to all the \(N_T\) ENs one by one

\end for
end if
end for
For each coded sub-message $\bigoplus_{\Phi \subset \Psi} W_{\Phi, \Psi}^\Psi$, each EN $p \in \Psi'$ caches $n$ sub-messages $\{W_{\Phi, \Psi}^p : p \in \Psi, \Psi \subset \Psi'\}$, and can decode the non-cached sub-messages $\{W_{p, \Psi}^{\Psi} : p \notin \Psi, \Psi \subset \Psi'\}$ by the method described in Theorem 1

The first and second terms on the right hand side of both (13) and (15) are the fronthaul NDT and the access NDT, respectively. It is clear that the fronthaul NDT decreases as the power scaling $r$ increases. When $r \to \infty$, the fronthaul NDT approaches zero, and the overall achievable NDT is dominated by the access NDT, given by
discussion of the achievable NDT in Theorem 1 and its comparison to [7, 9–11] are given in Section VI.

V. LOWER BOUND OF NDT

In this section, we present a lower bound of the minimum NDT, based on which we show that the achievable scheme is order-optimal.

Theorem 2 (Lower bound of NDT). For the cache-aided Fog-RAN with $N_T \geq 2$ ENs, each with a cache of normalized size $\mu_T$, $N_R \geq 2$ UEs, each with a cache of normalized size $\mu_R$, $N \geq N_R$ files, and a wireless fronthaul link with power scaling $r > 0$, the minimum NDT achieved by decentralized caching is lower bounded by

$$
\tau_{\text{lower}} = \max_{l_1 \in [N_R]} \frac{l_1(1-\mu_T)N_T(1-\mu_R)^{l_1}}{r} + \max_{l_2 \in [N_R]} \frac{l_2(1-\mu_R)^{l_2}}{\min \{l_2, N_T\}}.
$$

(26)

Proof. Since this is the proof of a lower bound, we focus on a specific UE demand that each UE $q \in [N_R]$ wants file $W_q$. Since ENs are assumed to be half-duplex, we will prove the lower bound of fronthaul NDT and access NDT separately.

1) Fronthaul Transmission: We first consider the fronthaul transmission. Consider the transmission of the files desired by the first $l_1$ UEs, for $l_1 \in [N_R]$. The proof is based on the following observation. Given received signals $Q_{1:N_T}$ from the MBS at all ENs and the caches $U_{1:N_T}$ at all ENs, one can construct the transmitted signals of all ENs. Then, given all the transmitted signals from the ENs and caches $V_{1:l_1}$ at the first $l_1$ UEs, one can obtain the desired files of these UEs almost surely. We have

$$
H(W_{1:l_1}|Q_{1:N_T}, U_{1:N_T}, V_{1:l_1}) = F\varepsilon_F + T_F\varepsilon_F \log P,
$$

where $W_{1:l_1}$ are files $\{W_1, W_2, \ldots, W_{l_1}\}$. Here, $\varepsilon_F$ and $\varepsilon_P$ are a function of file size $F$ and a function of power $P$, respectively, and satisfy $\lim_{F \to \infty} \varepsilon_F = 0$, $\lim_{P \to \infty} \varepsilon_P = 0$. Then, we have

$$
l_1F = H(W_{1:l_1}|W_{1:l_1+1:N})
$$

(27a)

$$
= I(W_{1:l_1};Q_{1:N_T}, U_{1:N_T}, V_{1:l_1}|W_{1:l_1+1:N})
$$

(27b)

$$
+ H(W_{1:l_1}|Q_{1:N_T}, U_{1:N_T}, V_{1:l_1}, W_{1:l_1+1:N})
$$

(27c)

$$
= H(Q_{1:N_T}, U_{1:N_T}, V_{1:l_1}|W_{1:l_1+1:N})
$$

(27d)

$$
- H(Q_{1:N_T}, U_{1:N_T}, V_{1:l_1}|W_{1:l_1+1:N})
$$

(27e)

where $W_{1:l_1+1:N}$ are files $\{W_{l_1+1}, W_{l_1+2}, \ldots, W_N\}$. Here, (27a) comes from the fact that conditioning reduces entropy. In (27c), $h(Q_{1:N_T})$ is bounded by

$$
h(Q_{1:N_T}) = I(Q_{1:N_T};S) + h(Q_{1:N_T}|S)
$$

(28a)

$$
= I(Q_{1:N_T};S) + T_F\varepsilon_F \log P
$$

(28b)

$$
\leq T_F(r \log P + \varepsilon_P \log P) + T_F\varepsilon_F \log P.
$$

(28c)

Here, $S$ is the transmitted signal of the MBS; (28b) is due to the fact that the conditional entropy $h(Q_{1:N_T}|S)$ comes from the noise received at ENs; (28c) follows from the capacity bound of the broadcast channel in high SNR regime. In (27c),

$$
H(U_{1:N_T}, V_{1:l_1}|W_{1:l_1+1:N})
$$

(29a)

$$
= H(U_{1:N_T}, V_{1:l_1})
$$

(29b)

$$
= \sum_{n=1}^{l_1} H(U_{1:N_T}^n, V_{1:l_1}^n)
$$

(29c)

Here, $U_{1:N_T}^n$, $V_{1:l_1}^n$ are the cached contents of files $\{W_1, W_2, \ldots, W_{l_1}\}$ at all the $N_T$ ENs and UEs $\{1, 2, \ldots, l_1\}$, respectively, and $U_{1:N_T}^n$, $V_{1:l_1}^n$ are the cached contents of file $n$ at all the $N_T$ ENs and UEs $\{1, 2, \ldots, l_1\}$, respectively; (29a) and (29b) come from the fact that the cache scheme does not allow intra-file coding or inter-file coding; (29c) comes from the fact that each EN and each UE caches a subset of $\mu_T$ and $\mu_R$ bits of each file independently and uniformly at random, respectively.

Combining (27a)–(28c) (29a)–(29c), and letting $F \to \infty$, $P \to \infty$, we obtain that

$$
\lim_{P \to \infty} \lim_{F \to \infty} \frac{T_F\varepsilon_F \log P}{P} = \frac{1}{l_1}(1-\mu_T)^{N_T}(1-\mu_R)^{l_1}.
$$

(30)

2) Access Phase: Next we consider the access transmission. The proof method is an extension of the approach in [4] Section VI] by taking decentralized cache scheme into account. Consider the first $l_2$ UEs, for $l_2 \in [N_R]$. The proof is based on the following observation. Given the received signals $Y_{1:l_2}$ and the cached contents $V_{1:l_2}$ of the $l_2$ UEs, one can successfully decode the desired files of these $l_2$ UEs. Thus, we have

$$
H(W_{1:l_2}|Y_{1:l_2}, V_{1:l_2}) = F\varepsilon_F.
$$

Similar to (27), we have

$$
l_2F = H(W_{1:l_2}|W_{1:l_2+1:N})
$$

(31a)

$$
= I(W_{1:l_2};Y_{1:l_2}, V_{1:l_2}|W_{1:l_2+1:N})
$$

(31b)

$$
+ H(W_{1:l_2}|Y_{1:l_2}, V_{1:l_2}, W_{1:l_2+1:N})
$$

(31c)

$$
= I(W_{1:l_2}|Y_{1:l_2}, V_{1:l_2}, W_{1:l_2+1:N}) + F\varepsilon_F
$$

(31d)

$$
= h(Y_{1:l_2}, V_{1:l_2}|W_{1:l_2+1:N}) + F\varepsilon_F
$$

(31e)

$$
\leq h(Y_{1:l_2}) + H(V_{1:l_2}|W_{1:l_2+1:N}) + F\varepsilon_F.
$$

(31f)
In (31f), $H(Y_{1 \sim l_2})$ is bounded by

$$h(Y_{1 \sim l_2}) = I(Y_{1 \sim l_2}; X_{1 \sim N_T}) + h(Y_{1 \sim l_2} X_{1 \sim N_T}) \geq T_A \min\{N_T, l_2\}(\log P + \varepsilon_P \log P) + T_A \varepsilon P \log P. \quad (32c)$$

Here, $X_{1 \sim N_T}$ are the transmitted signals from all the $N_T$ ENs; (32c) is due to the fact that the conditional entropy $h(Y_{1 \sim l_2} X_{1 \sim N_T})$ comes from the noise received at UEs; (32c) follows from the capacity bound of the $N_T \times l_2$ MIMO channel in high SNR regime, similar to the proof of [4, Lemma 5].

In (31f), $H(V_{1 \sim l_2} | W_{l_2+1 \sim N})$ is given by

$$H(V_{1 \sim l_2} | W_{l_2+1 \sim N}) = \sum_{n=1}^{l_2} H(V_{1 \sim l_2} | Y_{1 \sim l_2}) \quad (33b)$$

Note that (33b) is similar to (29), and the detailed explanation is omitted here.

Combining (31f), (32c), and setting $F \to \infty$, we obtain that

$$\lim_{P \to \infty} \lim_{F \to \infty} \frac{T_A \log P}{F} \geq \frac{l_2(1 - \mu R)}{\min\{l_2, N_T\}}. \quad (34)$$

Combining (30) and (34), and taking the maximum over $l_1, l_2 \in [N_R]$, the minimum NDT $\tau$ is lower bounded by

$$\tau = \lim_{P \to \infty} \lim_{F \to \infty} \frac{(T_F + T_A) \log P}{F} \geq \max_{l_1, l_2 \in [N_R]} \frac{l_1}{r} (1 - \mu_T)^{N_T} (1 - \mu_R)^{l_1} \max_{l_2 \in [N_R]} \frac{l_2(1 - \mu_R)}{\min\{l_2, N_T\}},$$

which finishes the proof of Theorem 2.

Comparing Theorem 1 and Theorem 2, the multiplicative gap between the upper and lower bounds is given in the following corollary, whose proof is in appendix.

**Corollary 1 (Gap of NDT).** The multiplicative gap between the upper and lower bounds of the minimum NDT of the considered system is within 12.

VI. NUMERICAL RESULTS AND DISCUSSIONS

In this section, we use numerical examples to compare the achievable NDT of our proposed scheme using decentralized caching with existing schemes, including centralized caching in [7, 9], mixed caching (centralized at ENs and decentralized at UEs) in [10], and decentralized caching (for two ENs only) in [11]. Note that [9] assumed wireless fronthaul, while [7, 10, 11] assumed dedicated fronthaul with capacity of $C_F = r \log P$ bits per symbol. Fig. 2 depicts the NDT when $N_T = 2, N_R = 5, \mu_T = \frac{1}{4}, \mu_R = \frac{1}{2}$. It is seen that when $r$ increases, the achievable NDT, as well as our proposed lower bound, decreases and finally approaches a constant as expected.

Comparing to the decentralized caching in [11], it is seen in Fig. 2 that our achievable NDT is better in most fronthaul capacity regions even though dedicated fronthaul link is considered in [11]. This is because EN cooperation in the access link is fully exploited by the careful design of fronthaul transmission in our scheme, while it is only exploited in [11] when transmitting some specific subfiles.

When $r$ is small, it is seen that our scheme with decentralized caching is inferior to the centralized caching in [9] as expected, since [9] can better utilize the cache memory. However, when $r \geq 2$, our scheme performs very close to [9] and even outperforms it when $2 \leq r \leq 6$. This is because an additional layer of coded multicasting opportunities based on the coded messages desired by UEs is exploited in the fronthaul link in our scheme as stated in Section III-B while in [9], the coded multicasting opportunities in the fronthaul link are only exploited by generating coded messages directly from requested subfiles $\{W_{q, \phi, \psi}\}$; we obtain a larger achievable per-user DoF than the one in [9] in the access channel by using interference neutralization and interference alignment jointly.

Comparing to the centralized caching in [7] and mixed caching in [10] with dedicated fronthaul, it is seen that our achievable NDT is even better than theirs when $r \geq 2$. This is because in their schemes, the fronthaul link is not used to deliver contents already cached at ENs to boost EN cooperation in the access link. Note that the authors in [8] state that coded multicasting is not useful in certain cases in the fronthaul delivery. However, by comparing to [7] with conventional uncoded caching at UEs, it is still seen that coded multicasting plays an important role in the access delivery in our scheme to reduce the sum NDT.

VII. CONCLUSION

In this paper, we investigated the latency performance of a Fog-RAN with wireless fronthaul and for arbitrary number of cache-equipped ENs and cache-equipped UEs, by using NDT as the performance metric. The system consists of two phases: a file-splitting based decentralized cache placement phase and a fronthaul-aided two-hop content delivery phase. In our proposed delivery scheme, coded multicasting opportunities

3Since [7] only considers EN caches, we add conventional uncoded caching at UEs in the plot of [7] for fair comparison.
are fully exploited in the fronthaul link by fetching both non-cached and cached contents of ENs to enhance EN cooperation in the access transmission. Then, the access link is changed into the cooperative X-multicast channels. We obtained both the achievable upper bound and theoretical lower bound of NDT for decentralized caching, with a multiplicative gap less than 12. It is shown that our decentralized caching scheme can balance the time between the fronthaul link and access link by the careful design of fronthaul transmission, and even outperforms the centralized schemes, mixed scheme, and decentralized scheme (with dedicated fronthaul) under certain conditions.

APPENDIX: PROOF OF COROLLARY 1

In Appendix, we aim to prove Corollary 1. We consider two cases to prove the gap, i.e., $N_T \geq N_R$ and $N_T < N_R$.

A. $N_T \geq N_R$

We first consider the case when $N_T \geq N_R$. The achievable upper bound of NDT is $\tau_{\text{upper}} = \sum_{m=0}^{N_R-1} \sum_{n=0}^{N_T} \tau_{m,n}$, where $\tau_{m,n}$ is given in (13) and (14). Taking $i = 0$ in (14), $\tau_{m,n}$ is bounded by

$$\tau_{m,n} \leq \frac{(N_R-1)(N_T)}{d_{m,n}}.$$  

We also have

$$\tau_{m,0} = \left( N_R \right) f_{m,0} + \left( \frac{N_R-1}{m} \right) f_{m,0},$$

When $N_T \geq N_R$, it is easy to see that $d_{m,n} \geq 1/2$ for $m \in [N_R - 1] \cup \{0\}, n \in [N_T]$. Then, $\tau_{\text{upper}}$ is upper bounded by (35). Taking $l_2 = 1$ in (26), the lower bound of NDT is lower bounded by

$$\tau_{\text{lower}} \geq \max_{l_i} \frac{l_i(1 - \mu_T)^N(1 - \mu_R)^{l_i}}{r} + (1 - \mu_R).$$  

Denote $g$ as the multiplicative gap, then the gap is bounded by

$$g \leq \frac{2(1 - \mu_R) + \frac{(1 - \mu_T)^N}{r} - \frac{1 - \mu_R}{\mu_R} \left[ 1 - (1 - \mu_R)^N \right]}{\max_{l_i} \frac{l_i(1 - \mu_T)^N(1 - \mu_R)^{l_i}}{r} + (1 - \mu_R)}.$$  

To upper bound $g$, we first consider

$$g_f = \frac{(1 - \mu_T)^N}{r} - \frac{1 - \mu_R}{\mu_R} \left[ 1 - (1 - \mu_R)^N \right] \frac{\max_{l_i} \frac{l_i(1 - \mu_T)^N(1 - \mu_R)^{l_i}}{r}}{\max_{l_i} \frac{l_i(1 - \mu_T)^N}{r}}.$$  

which can also be viewed as the gap in the fronthaul link. We consider four cases to upper bound $g_f$, i.e., (1) $N_R \leq 12$; (2) $N_R \geq 13, \mu_R \geq \frac{1}{12}$; (3) $N_R \geq 13, \frac{1}{12} \leq \mu_R < \frac{1}{12}$; (4) $N_R \geq 13, \mu_R \leq \frac{1}{12}$. Note that the broadcast channel in the fronthaul link is similar to the one-server shared link in [1], [6], and the proof here is similar to the one in [1], [6].

1) $N_R \leq 12$: In this case, using the inequality $(1 - \mu_R)^N R \geq 1 - N_R \mu_R$, we have

$$1 - \frac{\mu_R}{\mu_R} \left[ 1 - (1 - \mu_R)^N \right] \leq 1 - \left(1 - \mu_R \right)^N \leq 12(1 - \mu_R).$$

Letting $l_1 = 1$, $g_f$ is bounded by

$$g_f \leq 12 \frac{(1 - \mu_R)}{1 - \mu_R} = 12.$$  

2) $N_R \geq 13, \mu_R \geq \frac{1}{12}$: We have

$$1 - \frac{\mu_R}{\mu_R} \left[ 1 - (1 - \mu_R)^N \right] \leq 1 - \left(1 - \mu_R \right)^N \leq 12(1 - \mu_R).$$

Similar to Case 1 that $N_R \leq 12$, $g_f$ is also upper bounded by 12.
\[ \tau_{\text{upper}} \leq \sum_{m=0}^{N_R-1} \sum_{n=1}^{N_T} \frac{(N_R-1)(N_T)}{m,n} f_{m,n} \frac{N_R-1}{m} f_{m,0} \frac{N_R-1}{m+1} f_{m,0} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ \leq 2 \sum_{m=0}^{N_R-1} \sum_{n=0}^{N_T} \left( \frac{N_R-1}{m} \right) f_{m,n} + \frac{(1-\mu_T)^{N_T}}{r} \frac{N_R-1}{m+1} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_{m+1} (1-\mu_R)^{N_R-m} \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \frac{N_R-1}{N_R} \sum_{m=1}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_{m+1} (1-\mu_R)^{N_R-m} \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \left[ \frac{N_R-1}{N_R} \mu_{p,1}^{(1-\mu_R)^{N_R-p}} - (1-\mu_R)^{N_R} \right] \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \left[ 1 - (1-\mu_R)^{N_R} \right] \]

(35)

3) \( N_R \geq 13, \frac{1}{N_R} \leq \mu_R < \frac{1}{12} \): Letting \( l_1 = \left[ \frac{1}{4\mu_R} \right] \), we have

\[ \frac{\left( \frac{1}{4\mu_R} \right)}{(1-\mu_R)^{N_R}} \geq \left( \frac{1}{4\mu_R} \right) \left( 1 - \left( \frac{1}{4\mu_R} \right) \mu_R \right) \geq \left( \frac{1}{4\mu_R} \right) - 1 \left( 1 - \frac{1}{4\mu_R} \mu_R \right) \]

Then, \( g_F \) is upper bounded by

\[ g_F \leq \frac{1-\mu_R}{\mu_R} \left[ 1 - (1-\mu_R)^{N_R} \right] \]

\[ \leq \frac{1}{4\mu_R} - \frac{3}{4} \]

\[ = \frac{3}{16} - \frac{3\mu_R}{4} \]

\[ < \frac{1}{3/16 - 3/48} = 8. \]

4) \( N_R \geq 13, \mu_R < \frac{1}{N_R} \): Letting \( l_1 = \left[ \frac{N_R}{4} \right] \), we have

\[ \frac{\left( \frac{1}{4\mu_R} \right)}{(1-\mu_R)^{N_R}} \geq \left( \frac{1}{4\mu_R} \right) \left( 1 - \left( \frac{1}{4\mu_R} \right) \mu_R \right) \geq \left( \frac{1}{4\mu_R} \right) - 1 \left( 1 - \frac{1}{4\mu_R} \mu_R \right) \]

\[ \leq \frac{1}{4\mu_R} - 1 \left( 1 - \frac{1}{4\mu_R} \mu_R \right) \]

\[ \leq \frac{1}{4\mu_R} - 1 - \left( \frac{1}{4\mu_R} - 1 \right) \mu_R \]

\[ \leq \frac{1}{N_R} \left[ \frac{1}{N_R} - \mu_R \right] \]

\[ \leq 1 \left( 1 - \left( \frac{1}{N_R} - 1 \right) \mu_R \right) \]

\[ \leq \frac{1}{4 - \frac{1}{N_R} - \frac{3}{4} + \frac{1}{N_R}} < 8. \]

Combining all four cases, we find that \( g_F \leq 12 \) for all \( \mu_R, N_R \). Then, the gap \( g \) is upper bounded by

\[ g \leq 2(1-\mu_R) + 12 \max_{l_1} \frac{l_1}{\mu_R} \left( 1-\mu_R \right)^{N_R} \left( 1-\mu_R \right)^{l_1} \leq 12. \]

Thus, we proved the case when \( N_T \geq N_R \).

B. \( N_T < N_R \)

Now, we consider the case when \( N_T < N_R \). The achievable upper bound of NDT is \( \tau_{\text{upper}} = \sum_{m=0}^{N_R-1} \sum_{n=0}^{N_T} \tau_{m,n} \), where \( \tau_{m,n} \) is given in (13) and (14). Taking \( \tau = 0 \) in (14), \( \tau_{m,n} \) is bounded by

\[ \tau_{m,n} \leq \frac{(N_R-1)(N_T)}{d_{m,n}} \]

\[ \leq \frac{N_R-1}{N_R} \frac{N_T}{m} f_{m,n} \]

\[ \leq \frac{N_R-1}{N_R} \frac{N_T}{m+1} f_{m,0} \]

\[ \leq \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_{m+1} (1-\mu_R)^{N_R-m} \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \frac{N_R-1}{N_R} \sum_{m=1}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_{m+1} (1-\mu_R)^{N_R-m} \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \left[ \frac{N_R-1}{N_R} \mu_{p,1}^{(1-\mu_R)^{N_R-p}} - (1-\mu_R)^{N_R} \right] \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \left[ 1 - (1-\mu_R)^{N_R} \right] \]

\[ = 2(1-\mu_R) + \frac{(1-\mu_T)^{N_T}}{r} 1 - \mu_R \left[ 1 - (1-\mu_R)^{N_R} \right] \]

(35)
\[ \tau_{\text{upper}} \leq \sum_{m=0}^{N_R-1} \sum_{n=1}^{N_T} \left( \frac{(N_R-1)}{m} \right) \frac{d_{m,n}}{f_{m,n}} + \sum_{m=0}^{N_R-1} \left( \frac{(N_R-1)}{m} \right) f_{m,0} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ \leq \sum_{m=0}^{N_R-1} \frac{N_T}{N_T + N_R \frac{m}{m+1}} \sum_{n=0}^{N_T} \left( \frac{N_T}{n} \right) f_{m,n} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ = \sum_{m=0}^{N_R-1} \left( \frac{(N_R-1)}{m} \right) \frac{\mu_R^m (1 - \mu_R)^{N_R - m} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0}}{N_T + N_R \frac{m}{m+1}} \]

\[ = \frac{N_T - 1}{N_T} \sum_{m=0}^{N_R-1} \left( \frac{(N_R-1)}{m} \right) \mu_R^m (1 - \mu_R)^{N_R - m} + \frac{1}{N_T} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_R^m (1 - \mu_R)^{N_R - m} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ = \frac{N_T - 1}{N_T} \sum_{m=0}^{N_R-1} \left( \frac{(N_R-1)}{m} \right) \mu_R^m (1 - \mu_R)^{N_R - m} + \frac{1}{N_T \mu_R} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) \mu_R^m (1 - \mu_R)^{N_R - m} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \sum_{p=1}^{N_R} \left( \frac{N_R}{p} \right) \mu_R^p (1 - \mu_R)^{N_R - p} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \sum_{p=1}^{N_R} \left( \frac{N_R}{p} \right) \mu_R^p (1 - \mu_R)^{N_R - p} + \frac{1}{r} \sum_{m=0}^{N_R-1} \left( \frac{N_R}{m+1} \right) f_{m,0} \]

\[ = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \left( 1 - (1 - \mu_R)^{N_R} \right) + \frac{1 - \mu_R}{r} \left[ 1 - (1 - \mu_R)^{N_R} \right] \]

\[ = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \left( 1 - (1 - \mu_R)^{N_R} \right) + \frac{1 - \mu_R}{r} \left[ 1 - (1 - \mu_R)^{N_R} \right] \]

\[ \Rightarrow g \leq \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \left( 1 - (1 - \mu_R)^{N_R} \right) + \frac{1 - \mu_R}{r} \left[ 1 - (1 - \mu_R)^{N_R} \right] \]

\[ \Rightarrow g \leq \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \left( 1 - (1 - \mu_R)^{N_R} \right) + \frac{1 - \mu_R}{r} \left[ 1 - (1 - \mu_R)^{N_R} \right] \]

We also have

\[ \tau_{m,0} = \frac{(N_R)}{r} \sum_{m=0}^{N_R} \left( \frac{N_R}{m} \right) f_{m,0} \]

It is easy to see in [2] Lemma 1 that \( d_{m,n} \geq d_{m,1} = \frac{N_T - m}{N_T - 1} \) for \( m \in [N_R - 1] \cup \{0\}, n \in [N_T] \). Then, the achievable upper bound of NDT is bounded by (37). Using Theorem 2, the multiplicative gap \( g \) is bounded by (38). In (38), from the analysis when \( N_T \geq N_R \), we have

\[ \frac{(1 - \mu_R)^{N_T}}{r} \left[ 1 - (1 - \mu_R)^{N_R} \right] \leq 12. \]

Then, to bound \( g \) in (38), we first consider

\[ g_A \triangleq \frac{(N_R)}{N_T} (1 - \mu_R) + \frac{1 - \mu_R}{N_T \mu_R} \left[ 1 - (1 - \mu_R)^{N_R} \right] \]

\[ \max_{l_2 \in [N_R]} \frac{l_2(1 - \mu_R)^{l_2}}{\min\{l_2, N_T\}} \geq \frac{N_R - 1}{N_T} (1 - \mu_R) \]

\[ \Rightarrow \max_{l_2 \in [N_R]} \frac{l_2(1 - \mu_R)^{l_2}}{\min\{l_2, N_T\}} \geq 1 - \mu_R. \]

Letting \( l_2 = N_R \), we have

\[ \max_{l_2 \in [N_R]} \frac{l_2(1 - \mu_R)^{l_2}}{\min\{l_2, N_T\}} \geq \frac{N_R - 1}{N_T} (1 - \mu_R) \]

\[ \Rightarrow \max_{l_2 \in [N_R]} \frac{l_2(1 - \mu_R)^{l_2}}{\min\{l_2, N_T\}} \geq 1 - \mu_R. \]
Combining (40), (42), (43), \( g_A \) is upper bounded by
\[
g_A = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{\frac{1}{4} \mu_R}{N_T} \left[ 1 - (1 - \mu_R)^N_R \right]
\]
\[
\leq \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{N_R}{N_T - 1} \frac{\frac{1}{4} \mu_R}{N_T - 1} \left[ 1 - (1 - \mu_R)^N_R \right]
\]
\[
< 1 + \frac{32}{5} = 7.3.
\]

2) \( \frac{1}{2N_T} \leq \mu_R < \frac{1}{N_T} \): Letting \( l_2 = \left[ \frac{1}{4 \mu_R} \right] \), we have
\[
\max_{l_2} l_2 (1 - \mu_R)^{l_2} \min\left\{ l_2, N_T \right\}
\]
\[
\geq \left[ \frac{1}{4 \mu_R} \right] (1 - \mu_R)^{\frac{1}{2N_T}} \\min\left\{ \left[ \frac{1}{4 \mu_R} \right], N_T \right\}
\]
\[
\geq \frac{1}{4 \mu_R} \left[ 1 - \left( \frac{1}{4 \mu_R} \right) \mu_R \right]
\]
\[
\geq 1 - \left( \frac{1}{4 \mu_R} \right) + \frac{1}{2 \mu_R} N_T
\]
\[
\geq \frac{\frac{1}{4 \mu_R} - \frac{1}{2 \mu_R} N_T}{4} = \frac{5}{32 N_T \mu_R}. \quad (42)
\]
We also have
\[
\frac{1}{N_T \mu_R} [1 - (1 - \mu_R)^N_R] \leq \frac{1}{N_T \mu_R}. \quad (43)
\]
Combining (40), (42), (43), \( g_A \) is upper bounded by
\[
g_A = \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{\frac{1}{4} \mu_R}{N_T} \left[ 1 - (1 - \mu_R)^N_R \right]
\]
\[
\leq \frac{N_T - 1}{N_T} (1 - \mu_R) + \frac{1}{N_T \mu_R} \frac{\frac{1}{4} \mu_R}{N_T - 1} \left[ 1 - (1 - \mu_R)^N_R \right]
\]
\[
< 1 + \frac{32}{5} = 37.5.
\]

3) \( \mu_R \geq \frac{1}{N_T} \): Letting \( l_2 = \left[ \frac{1}{4 \mu_R} \right] \), we have
\[
\max_{l_2} l_2 (1 - \mu_R)^{l_2} \min\left\{ l_2, N_T \right\}
\]
\[
\geq \left[ \frac{1}{4 \mu_R} \right] (1 - \mu_R)^{\frac{1}{4 \mu_R}} \\min\left\{ \left[ \frac{1}{4 \mu_R} \right], N_T \right\}
\]
\[
= (1 - \mu_R)^{\frac{1}{4 \mu_R}}
\]
\[
\geq 1 - \frac{1}{4 \mu_R} \mu_R
\]
\[
\geq 1 - \frac{1}{4 \mu_R} \mu_R = \frac{3}{4}. \quad (44)
\]
We also have
\[
\frac{1}{N_T \mu_R} [1 - (1 - \mu_R)^N_R] \leq \frac{1}{N_T \mu_R} \leq \frac{1}{N_T \frac{1}{4 \mu_R}} = 4. \quad (45)
\]

From the above three cases, we find that \( g_A < 12 \). Then the multiplicative gap \( g \) is bounded by (46), when \( N_T < N_R \).

Thus we finished the proof of Corollary 11 that the multiplicative gap is within 12.
