Abstract: Rijndael-The AES is 128-bit block cipher based on an elegant algebraic structure over \( F_{2^8} \). This cipher employs a simple approach to its substitution, permutation (SP) operations. We take a close look on the Key Expansion Mechanism of Rijndael - The AES. This study highlights on the presence of the cascading effect in its key expansion mechanism. Thus, lowering the brute-force key guess attack by a factor of \( 2^{31} \). Hence, for the key size of 128 bits the key diversity is \( 2^{97} \) instead of \( 2^{128} \).

Key words: Cascading effect, key expansion mechanism, AES

INTRODUCTION

Rijndael Algorithm\(^1\)\(^-\)\(^3\) was designed by two Belgian cryptographers: Vincent Rijmen and John Daemen, as one of the candidates for the Advanced Encryption Standard (AES) selection. The AES committee was formulated by the U.S. Government under the umbrella of National Institute of Standards and Technology (NIST) to find another cryptographic algorithm in order to replace the existing 64-bit block cipher of 1977 - the Data Encryption Standards (DES) to protect sensitive digital information over the next few decades.

After a stringent qualifying process of three rounds involving the whole world’s cryptographic community\(^4\)\(^-\)\(^6\), Rijndael algorithm was proposed by the AES committee as Advanced Encryption Standard – The AES on Nov. 26, 2001. Later on May 26, 2002 NIST endorsed it as Federal Information Processing Standard namely FIPS-197 replacing DES (FIPS-46).

Rijndael possesses an elegant algebraic structure over \( F_{2^8} \).\(^6\)\(^-\)\(^9\). It supports a variable block size and variable key size of 128, 160, 192, 224 or 256 bits each. But for the AES, its block size is fixed to 128-bits and keeping the variable key size of 128, 192 and 256 bits. It has 10, 12 or 14 iterations of round transformations depending on the key size of 128, 192 or 256 bits respectively in conjunction with an initial round of key addition. Each (except the last) round transformation function is composed of the four sub transformation functions: Byte Substitution or bs, Row Shift or rs, Mix Column or mc and Add Round Key or ak. The last round transformation does not include the mc function.

In this study we present an analysis of the block cipher Rijndael while concentrating on its 128-bit version. This cipher employs a simple approach to its substitution, permutation (SP) operations. We take a close look on its Key Expansion Mechanism; highlighting on the presence of the repeated pattern in the expanded key bytes in a peculiar manner, which we name as the cascading effect. Due to the presence of this pattern in the key expansion mechanism, the brute-force key guess attack on Rijndael key schedule is lowered by a factor of \( 2^{31} \). Hence, the key size of 128 bits has a key diversity of \( 2^{97} \) instead of \( 2^{128} \).

Notations: We fix the block size and key size to 128 bits. We consider the 10 round version. We use the following notations.

Let for all round index \( i = 0, \ldots, 10 \) and byte index \( j = 0, \ldots, 15 \) :

\[ X^i_j : j\text{th text byte of } i\text{-th round (in particular, } X^0_j \text{ is the initial input plain text byte and is fixed)} \]

\[ X^{i+1}_j : j\text{th cipher text byte} \]

\[ K^i_j : j\text{th expanded key byte of } i\text{-th round (in particular, } K^0_j \text{ is the user defined key } \}

\[ W[i] = i\text{-th word key of } 32\text{ bits.} \]

\[ k_n: n\text{th key byte}, \]

\[ N_t = (\text{key size})/32 = 128/32 = 4. \]

\[ N_b = (\text{block size})/32 = 128/32 = 4. \]

\[ N_r = \text{No. of cipher rounds} = 10. \]

We use the standard convention of representing elements of \( F_{2^8} \) as polynomials of degree 7, over \( F_2 \).

We also adopt the standard practice of treating the elements of \( F_{2^8} \) as integers in the range 0, \ldots, 255.
Thus for example, \( \alpha \in \mathbb{F}_{2^8} \) with \( \alpha = x^7 + x^6 + x^2 + x^1 + 1 \) would be referred as \( \alpha = 199 \), without ambiguity.

We define three functions namely Rotbyte(), Rc(), Rcon().

i. Rotbyte(): rotates the bytes of key within the word, when word oriented structure is considered for key expansion mechanism. If \( k_0, k_1, k_2, k_3 \) are four bytes of \( i \)-th key-word \( W[i] \) arranged in big endian format, Rotbyte\( (W[k_0, k_1, k_2, k_3]) = W[k_1, k_2, k_3, k_0] \).

The byte substitution transformation of Rijndael uses an S-box, generated over \( \mathbb{F}_{2^8} \) with \( (x+1) \equiv (03_{\text{base 16}}) \) as primitive element and \( g(x) = (x^8 + x^4 + x^3 + x + 1) \) as the defining irreducible polynomial along with an affine transformation of \( (x^8 + x^4 + x^3 + x + 1) \equiv (63_{\text{base 16}}) \). Thus, bs, using S-box, transforms the individual byte \( a(x) \) to \( bs(a(x)) \).

Mathematically,
\[
bs(a(x)) = (x^8 + x^4 + x^3 + x + 1) + c(x)(x^8 + x^4 + x^3 + x + 1) \pmod{(x^8 + 1)}
\]
where, \( c(x) = a(x)^{-1} \pmod{g(x)} \)

Similarly
\[
bs(W[k_0, k_1, k_2, k_3]) = W[bs(k_0), bs(k_1), bs(k_2), bs(k_3)]
\]
and
\[
\text{Rotbyte } (bs(W[k_0, k_1, k_2, k_3])) = W[bs(k_1), bs(k_2), bs(k_3), bs(k_0)]
\]

ii. Rc\( (a(x)) \) is another round dependent byte oriented constant function defined over \( \mathbb{F}_{2^8} \). \( \text{POW}(a(x)) \) contains powers of \( a(x) \) in the field. Then
\[
\text{Rc}(a(x)) = \text{POW}(a(x)) \pmod{g(x)}
\]
In particular, for \( a(x) \in \{1, 2, \ldots, 10\} \)
\[
\text{Rc}(a(x)) = \{1, 2, 4, 8, 16, 32, 64, 128, 27, 54\}
\]

iii. Rcon\( (a(x)) \) is a round dependent word oriented function such that \( \text{Rcon}(a(x)) = (\text{Rc}(a(x)), 0, 0, 0) \).

Here the commas define separation of each byte arranged in big endian format.

Brief description of Rijndael internals: Rijndael has an elegant algebraic structure over \( \mathbb{F}_{2^8} \). The input plain text or the output cipher text of block size of 128-bits is viewed as a \( 4 \times 4 \) matrix of 16 bytes arranged in a column major format. Rijndael consists of an initial round of key addition (ak) followed by 10 iterations of round transformations for the key size of 128-bits. Each (except the last) round transformation function is composed of the four sub transformation functions: Byte Substitution or bs, Row Shift or rs, Mix Column or mc and Add Round Key or ak. The last round transformation does not include the mc function.

Byte Substitution transformation: bs: This is the only non-linear transformation in the entire Rijndael structure. It operates independently on each byte using a substitution table (S-box). The S-box, which is invertible in nature, is composed of two transformations:

a) Taking multiplicative inverse of the desired byte in the finite field \( GF(2^8) \) with \( (x+1) \equiv (03_{\text{base 16}}) \) as primitive element and \( g(x) = (x^8 + x^4 + x^3 + x^1 + 1) \) as the defining irreducible polynomial. The element \( 00_{\text{base 16}} \) is mapped on to itself.

b) Applying an affine transformation of \( (x^8 + x^4 + x^3 + x^1 + 1) \) equivalently \( 63_{\text{base 16}} \).

Thus, the byte substitution operation transforms a byte \( a(x) \) to \( bs(a(x)) \) as per the following relation. Let
1. \( c(x) = a(x)^{-1} \pmod{g(x)} \)
2. \( bs(a(x)) = (x^8 + x^4 + x^3 + x + 1) + c(x)(x^8 + x^4 + x^3 + x^1 + 1) \pmod{(x^8 + 1)} \)

The inverse S-box is constructed by taking an inverse affine transform followed by a multiplicative inverse in the finite field \( \mathbb{F}_{2^8} \).

1. \( c(x) = (x^8 + 1) \)
2. \( bs(a(x))(x^8 + x^4 + x) \pmod{(x^8 + 1)} \)

Row shift transformation: rs: The 16 input bytes are arranged in a column major format of a \( 4 \times 4 \) matrix. To achieve the desired confusion, a linear transformation rs is applied. Here, the bytes in each row of the matrix are given a cyclic left shift. For \( i = 1, 2, 3, 4 \) the bytes in the \( i \)-th row are circularly left shifted by \( (i-1) \) bytes.

The inverse of a row shift transformation is obtained by cyclically shifting the bytes in the reverse direction i.e. circularly right shifting 0, 1, 2 and 3 bytes in the first, second, third and fourth row of the \( 4 \times 4 \) input matrix respectively.

Mix column: mc: The linear transformation mix column provides the diffusion by mixing the bits of each column. The function \( \beta(z) \), given below, operates on the input column by treating it as a degree three polynomial in \( \mathbb{F}_2 \). This polynomial is multiplied by a rotated version of a standard polynomial \( m(z) \in \mathbb{F}_2 \). Given by:
\[
[m(z)] = 03z^3 + 01z^2 + 01z^1 + 02
\]
and reduced modulo the polynomial \((z^4 + 1) \in F_2[z]\).

Here the coefficients denote elements of \(F_2\). It is known that the coefficients of \(m(z)\) are so chosen that the result \(\beta(z) m(z)\) is invertible modulo \((z^4 + 1)\) although this polynomial is reducible over \(F_2\).

For example, a column of \(mc\), \([a_0, a_1, a_2, a_3]^T\) is considered as:
\[
\beta(z) = a_0z^3 + a_1z^2 + a_2z + a_3 \in F_2[z]
\]
Then,
\[
m(z) \beta(z) = ((03 \cdot a_0)z^3 + (03 \cdot a_1 + 01 \cdot a_3)z^2
\]
\[
+ (03 \cdot a_0 + 02 \cdot a_1 + 01 \cdot a_2)z
\]
\[
+ (01 \cdot a_0 + 02 \cdot a_1 + 02 \cdot a_3)z
\]
\[
+ (01 \cdot a_0 + 02 \cdot a_1 + 02 \cdot a_3)z^0
\]
\[
\mod (z^4 + 1)
\]
\[
m(z) \beta(z) = \begin{bmatrix}
02 & 03 & 01 & 01 \\
01 & 02 & 03 & 01 \\
01 & 01 & 02 & 03 \\
03 & 01 & 01 & 02
\end{bmatrix} \begin{bmatrix}
a_0 \\
a_1 \\
a_2 \\
a_3
\end{bmatrix}
\]

The inverse of Mix column transformation is similar to the forward operation with the only difference that the inverse of the fixed polynomial i.e. \([m(z)]^{-1}\) is used and it is given by
\[
[m(z)]^{-1} = 11z^3 + 13z^2 + 09z + 14
\]

Hence,
\[
[m(z)]^{-1} \beta(z) = \begin{bmatrix}
14 & 11 & 13 & 09 \\
09 & 14 & 11 & 13 \\
13 & 09 & 14 & 11 \\
11 & 13 & 09 & 14
\end{bmatrix} \begin{bmatrix}
a_0 \\
a_1 \\
a_2 \\
a_3
\end{bmatrix}
\]

Add round key: \(ak\): In this function, the round key is added to the current byte as bit-wise exclusive OR. The XOR operation is the inverse of itself.

Key expansion mechanism of rijndael: The Key expansion mechanism for 128-bit key size, in Rijndael is defined in the following manner:

The expanded key of \(N_0 \cdot (N_i + 1) = 44\) words is derived from the 4 words of the user defined key. The first \(N_k\) \((= 4)\) words, \(W[0], \ldots, W[3]\) of the expanded key are filled with the user defined original cipher key bits. The subsequent key words for all \(N_k \leq i < (N_0 \cdot (N_i + 1))\) i.e. \(4 \leq i < 44\) alternatively \(i = \{4, \ldots, 43\}\) are given by
\[
W[i] = \begin{cases}
W[i-N_k] \circ\circ \text{Rotbyte} \left( W[i-1] \right) \\
\circ\circ \text{Rcon} \left( i/N_k \right) \quad \forall i = 0 \left( N_k \right) \\
W[i-N_k] \circ\circ W[i-1] \\
\forall i \neq 0 \left( N_k \right)
\end{cases}
\]

Till now we have discussed briefly the internals of Rijndael algorithm. Now we are going to present the modified form of the \(ak\) in the subsequent sections.

Modified key expansion mechanism of rijndael: As the functions \(bs(.)\) and \(Rcon(.)\) transformations inherently operate on individual bytes of every input word, thus, a modified byte oriented version for key expansion algorithm can be derived. Therefore, for the present study with key size and block size of 128 bits and 10 cipher rounds, a total of \(176 \left( = 4 \cdot (N_k \cdot (N_i + 1)) \right)\) bytes from the 16 bytes (=128 bits) of the user defined key \(k_n\) with \(n = \{0, \ldots, 15\}\) are to be expanded.

First \(4N_k\) \((=16)\) bytes, defined as \(K_0^n : \{k_0, k_1, k_2, \ldots, k_{15}\}\) of the expanded key are filled with the original 128 user defined key bits stored in big endian format. For subsequent rounds, the expanded key bytes at \(n = \{16, \ldots, 175\}\) are given by the following relations:
when \(n = 0 \left( mod 4 \cdot N_k \right)\), the four consecutive key bytes at \(n\) to \(n+3\) locations are obtained through:
\[
k_{n} = k_{n-16} \circ\circ bs \left( k_{n-3} \right) \circ\circ Rcn \left( n/16 \right)
\]

\[
k_{n+1} = k_{(n+1)-16} \circ\circ bs \left( k_{n-2} \right)
\]

\[
k_{n+2} = k_{(n+2)-16} \circ\circ bs \left( k_{n-1} \right)
\]

\[
k_{n+3} = k_{(n+3)-16} \circ\circ bs \left( k_{n-4} \right)
\]

The subsequent expanded key bytes for a particular round i.e. from \((n+4)\)th byte to \((n+15)\)th byte of \(k_n\), are obtained through:
\[
k_{n} = k_{n-16} \circ\circ k_{n-4}
\]

Alternatively, these expanded key bytes can be obtained in the form of round keys \(K_i^n\) through the following relations with the original key bytes filled at \(i = 0\) \& \(j = 0, \ldots, 14\) in \(K_0^n\). For \(0 \leq i < 10\)
\[
K_i^0 = K_i^0 \circ\circ bs \left( K_i^0 \right) \circ\circ \text{Rc}(i+1)
\]

\[
K_i^{i+1} = K_i^{i+1} \circ\circ bs \left( K_i^{i+1} \right)
\]

\[
K_i^{i+2} = K_i^{i+2} \circ\circ bs \left( K_i^{i+2} \right)
\]

\[
K_i^{i+3} = K_i^{i+3} \circ\circ bs \left( K_i^{i+3} \right)
\]

\[
K_i^{i+4} = K_i^{i+4} \circ\circ bs \left( K_i^{i+4} \right)
\]

In order to guess the keys used for encrypting the data we take a close look at the key expansion mechanism of Rijndael and try to derive some relationship between expanded key values and the initial key values that are stored in \(K_0^n\). The following
are our observations for the first round of expanded key values:

Let \( K_0 \) \( : \{ k_0, k_1, k_2, k_3, k_{12}, k_{13}, k_{14}, k_{15} \} \); the mentioned eight key bytes are assumed to be known. Hence, \( K_i \) the first round keys can be obtained as per the following relations:

\[
\begin{align*}
K'_0 &= K_0^0 \oplus \{ K_0^0 \oplus \text{bs} \{ K_{15}^0 \} \oplus \text{Rc}(1) = K_0^0 \oplus K_{15}^0 \\
K'_1 &= K_1^0 \oplus \{ K_1^0 \oplus \text{bs} \{ K_{14}^0 \} \ = K_1^0 \oplus K_{14}^0 \\
K'_2 &= K_2^0 \oplus \{ K_2^0 \oplus \text{bs} \{ K_{13}^0 \} \ = K_2^0 \oplus K_{13}^0 \\
K'_3 &= K_3^0 \oplus \{ K_3^0 \oplus \text{bs} \{ K_{12}^0 \} \ = K_3^0 \oplus K_{12}^0 \\
K'_4 &= K_4^0 \oplus K_5^0 \oplus \{ K_0^0 \oplus \text{bs} \{ K_{10}^0 \} \oplus \text{Rc}(1) = K_4^0 \oplus K_5^0 \oplus K_{10}^0 \\
K'_5 &= K_6^0 \oplus K_7^0 \oplus \{ K_1^0 \oplus \text{bs} \{ K_{11}^0 \} = K_6^0 \oplus K_7^0 \oplus K_{11}^0 \\
K'_6 &= K_{10}^0 \oplus \{ K_{11}^0 \oplus \text{bs} \{ K_{15}^0 \} = K_{10}^0 \oplus K_{11}^0 \oplus K_{15}^0 \\
K'_7 &= K_{12}^0 \oplus \{ K_{13}^0 \oplus \text{bs} \{ K_{15}^0 \} = K_{12}^0 \oplus K_{13}^0 \oplus K_{15}^0 \\
\end{align*}
\]

\[ \text{(1)} \]

Now, using the relations (1) in conjunction with our assumptions, we can evaluate \( K'_0 \) to \( K'_8 \), as all the variables on right hand side of (1) are known. Then using relations (2); \( K'_8 \) to \( K'_9 \) can be evaluated in \( 2^{32} \) operational trials. Using the relations (4) \( K'_8 \) to \( K'_{11} \) (or \( K'_9 \) to \( K'_{12} \) to \( K'_{13} \) can be evaluated in \( 2^{32} \) operations. Therefore, in all \( 2^{32} + 2^{32} = 2^{33} \) operations are required to evaluate all \( K_0 \) to \( K_{15} \). Alternatively, \( K'_0 \) to \( K'_{15} \) can be evaluated in \( 2^{31} \) operations due to the presence of the cascading effect in Rijndael key expansion mechanism. Thus, together with the prior knowledge of the eight key bytes specifically \( k_0, k_1, k_2, k_3, k_{12}, k_{13}, k_{14}, k_{15} \) we can determine the remaining 8 key bytes in \( 2^{13} \) operations instead of \( 2^{64} \). Similarly, if four key bytes i.e. \( k_0, k_1, k_2, k_3 \) are known then we require only \( 2^{65} (=2^{32} \times 2^{33}) \) trials and not \( 2^{96} \) to determine remaining 12 key bytes. In general with \( 2^{97} \) \((=2^{32} \times 2^{65})\) trials we can determine the key.

**CONCLUSION**

Due to the presence of cascading effect in Rijndael’s key expansion mechanism the brute-force key guess attack for the key size of 128 bits can be launched in \( 2^{97} \) operations instead of \( 2^{128} \). Hence, the key diversity for the key size of 128 bits is lowered by a factor of \( 2^{31} \). Further, the key diversity for the key size of 192 and 256 bits has to be explored on the similar lines.
