Abstract
We give a new proof that compact infra-solvmanifolds with isomorphic fundamental groups are smoothly diffeomorphic. More generally, we prove rigidity results for manifolds which are constructed using affine actions of virtually polycyclic groups on solvable Lie groups. Our results are derived from rigidity properties of subgroups in solvable linear algebraic groups.

1 Introduction
A closed manifold $M$ is called topologically rigid if every homotopy equivalence $h: N \to M$ from another manifold $N$ is homotopic to a homeomorphism. The Borel conjecture expects every closed aspherical manifold to be topologically rigid. The manifold $M$ is called smoothly rigid if every homotopy equivalence is homotopic to a diffeomorphism. Geometric methods are useful to prove smooth rigidity inside some classes of closed aspherical manifolds. Well known cases are, for example, locally symmetric spaces of non-compact type [28], or flat Riemannian manifolds [6]. In this paper, we study the smooth rigidity problem for infra-solvmanifolds. These manifolds are constructed by considering isometric affine actions on solvable Lie groups.

The fundamental group of an infra-solvmanifold is a virtually polycyclic group. A result of Farrell and Jones [12] on aspherical manifolds with virtually polycyclic fundamental group shows that infra-solvmanifolds are topologically rigid. Yet, an argument due to Browder [2] implies that there exist smooth manifolds which are homeomorphic but not diffeomorphic to the $n$-torus, for $n \geq 5$. Farrell and Jones [13] proved that any two compact infrasolvmanifolds of dimension not equal to four, whose fundamental groups are isomorphic, are diffeomorphic. This generalizes previous results of Bieberbach [3] on compact flat Riemannian manifolds, Mostow [24] on compact solv-manifolds and of Lee and Raymond [21] on infra-nilmanifolds. The proof of Farrell and Jones requires smoothing theory and the topological rigidity result. Recent results of Wilking

* e-mail: oliver@math.ethz.ch
on rigidity properties of isometric actions on solvable Lie-groups imply the smooth rigidity of infra-solvmanifolds in all dimensions, giving an essentially geometric proof.

In well known cases, smooth rigidity properties of geometric manifolds are closely connected to rigidity properties of lattices in Lie groups. The aim of the present paper is to establish the smooth rigidity of infra-solvmanifolds from natural rigidity properties of virtually polycyclic groups in linear algebraic groups. More generally, we prove rigidity results for manifolds which are constructed using affine, not necessarily isometric, actions of virtually polycyclic groups on solvable Lie groups. This approach leads us to a new proof of the rigidity of infra-solvmanifolds, and also to a geometric characterization of infra-solvmanifolds in terms of polynomial actions on affine space $\mathbb{R}^n$. As an application of the latter point of view we compute the cohomology of an infra-solvmanifold using the finite-dimensional complex of polynomial differential forms. This generalizes a result of Goldman on compact complete affine manifolds. As another application, we show that every infra-solvmanifold has maximal torus-rank. Our approach towards rigidity of infra-solvmanifolds also suggests to study the rigidity-problem for the potentially bigger class of manifolds which are constructed using affine actions of virtually polycyclic groups on solvable Lie groups. Our main result establishes smooth rigidity for virtually polycyclic affine actions if the holonomy of the action is contained in a reductive group, generalizing the particular case of isometric actions.

**Infra-solvmanifolds** We come now to the definition of infra-solvmanifolds. Let $G$ be a Lie-group and let $\text{Aff}(G)$ denote the semi-direct product $G \rtimes \text{Aut}(G)$, where $\text{Aut}(G)$ is the group of automorphisms of $G$. We view $\text{Aff}(G)$ as a group of transformations acting on $G$. If $\Delta$ is a subgroup of $\text{Aff}(G)$ then let $\Delta_0$ denote its connected component of identity, and $\text{hol}(\Delta) \leq \text{Aut}(G)$ its image under the natural homomorphism $\text{Aff}(G) \to \text{Aut}(G)$.

**Definition 1.1** An *infra-solvmanifold* is a manifold of the form $\Delta \backslash G$, where $G$ is a connected, simply connected solvable Lie group, and $\Delta$ is a torsion-free subgroup of $\text{Aff}(G)$ which satisfies (1) the closure of $\text{hol}(\Delta)$ in $\text{Aut}(G)$ is compact.

The manifold $\Delta \backslash G$ is a smooth manifold with universal cover diffeomorphic to $\mathbb{R}^m$, $m = \dim G - \dim \Delta_0$, where $\Delta_0$ is the connected component of identity in $\Delta$. The fundamental group of $\Delta \backslash G$ is isomorphic to $\Gamma = \Delta / \Delta_0$. It is known that $\Delta \backslash G$ is finitely covered by a solv-manifold, i.e., a homogeneous space of a solvable Lie group. By a result of Mostow the torsion-free group $\Gamma$ is then a virtually polycyclic group. (Recall that a group $\Gamma$ is called virtually polycyclic (or polycyclic by finite) if it contains a subgroup $\Gamma_0$ of finite index which is polycyclic, i.e., $\Gamma_0$ admits a finite normal series with cyclic quotients. The number of infinite cyclic factors in the series is an invariant of $\Gamma$ called the rank of $\Gamma$.) If $\Delta \backslash G$ is compact then $\dim \Delta \backslash G$ equals the rank of $\Gamma$. Not every smooth manifold which is finitely covered by a compact solvmanifold is diffeomorphic to an infra-solvmanifold. By the work of Wall et al. (see [20]), there exist fake tori which are finitely covered by standard tori. Consequently, these smooth manifolds do not carry any infra-solv structure.
**Main results**  Let $\Gamma$ be a torsion-free virtually polycyclic group. To $\Gamma$ we associate, in a functorial way, a solvable by finite real linear algebraic group $H_\Gamma$ which contains $\Gamma$ as a discrete and Zariski-dense subgroup. The group $H_\Gamma$ is called the real algebraic hull for $\Gamma$. The construction of the algebraic hull for $\Gamma$ extends results of Malcev [23] on torsion-free nilpotent groups, and results of Mostow [26] on torsion-free polycyclic groups. The extended construction was first announced in [4]. The details are provided in Appendix A of this paper.

We explain now the role the real algebraic hull plays in the construction of infra-solvmanifolds. Let $T \leq H_\Gamma$ be a maximal reductive subgroup, and let $U$ denote the unipotent radical of $H_\Gamma$. Then $H_\Gamma$ decomposes as a semi-direct product $H_\Gamma = U \cdot T$. The splitting induces an injective homomorphism $\alpha_T : H_\Gamma \to \text{Aff}(U)$ and a corresponding affine action of $\Gamma \leq H_\Gamma$ on $U$. The quotient space

$$M_\Gamma = \alpha_T(\Gamma) \backslash U$$

is a compact aspherical manifold of dimension $n = \text{rank} \Gamma$, and has universal cover $U = \mathbb{R}^n$. In fact, we show that $M_\Gamma$ is an infra-solvmanifold. We call every manifold $M_\Gamma$ which arises by this construction a standard $\Gamma$-manifold.

We prove:

**Theorem 1.2** Let $\Gamma$ be a torsion-free virtually polycyclic group. Then $M_\Gamma$ is a compact infra-solvmanifold and the fundamental group $\pi_1(M_\Gamma)$ is isomorphic to $\Gamma$. Every two standard $\Gamma$-manifolds are diffeomorphic and every given isomorphism of fundamental groups of standard $\Gamma$-manifolds is induced by a smooth diffeomorphism.

Let $G$ be a connected, simply connected Lie group, and let $\mathfrak{g}$ denote its Lie algebra. The group $\text{Aut}(G)$ attains the structure of a real linear algebraic group since it has a natural identification with the group $\text{Aut}(\mathfrak{g})$ of Lie algebra automorphisms of $\mathfrak{g}$. Our main result is:

**Theorem 1.3** Let $G$ be a connected, simply connected solvable Lie group. Let $\Delta \leq \text{Aff}(G)$ be a solvable by finite subgroup which acts freely and properly on $G$ with compact quotient manifold $M = \Delta \backslash G$. Assume that one of the following two conditions is satisfied:

i) $G$ is nilpotent, or

ii) $\text{hol}(\Delta) \leq \text{Aut}(G)$ is contained in a reductive subgroup of $\text{Aut}(G)$.

Then the group $\Gamma = \Delta / \Delta_0$ is virtually polycyclic, and $M$ is diffeomorphic to a standard $\Gamma$-manifold.

We deduce:

**Theorem 1.4** Every compact infra-solvmanifold is smoothly diffeomorphic to a standard $\Gamma$-manifold.

**Corollary 1.5** Compact infra-solvmanifolds are smoothly rigid. In particular, every two compact infra-solvmanifolds with isomorphic fundamental groups are smoothly diffeomorphic.
Theorem 1.2 also implies the following result which was first proved by Auslander and Johnson [2]. Their construction is different from ours.

**Corollary 1.6** Every torsion-free virtually polycyclic group is the fundamental group of a compact infra-solvmanifold.

The torus rank \( r \) of a manifold \( M \) is the maximum dimension of a torus which acts almost freely and smoothly on \( M \). For a closed aspherical manifold \( M \), \( r \) is bounded by the rank of the center of the fundamental group. If \( r \) equals the rank of the center then the torus rank of \( M \) is said to be maximal. It is known (see [22]) that the torus rank of a solvmanifold is maximal and the result is expected to hold for infra-solvmanifolds as well. It is straightforward to see that standard \( \Gamma \)-manifolds admit maximal torus actions. Therefore, we also have:

**Corollary 1.7** Every infra-solvmanifold has maximal torus rank.

Let \( U \) be a connected, simply connected, nilpotent Lie group, and let \( u \) denote its Lie-algebra. Nomizu [29] proved that the cohomology of a compact nilmanifold \( M = U/\Gamma \), where \( \Gamma \leq U \) is a lattice, is isomorphic to the cohomology of the complex of left invariant differential forms on \( U \). This means that the cohomology of the nilmanifold \( M \) is computed by the Lie algebra cohomology \( H^*(u) \). Now let \( \Gamma \) be a torsion-free virtually polycyclic group and \( M_{\Gamma} \) a standard \( \Gamma \)-manifold. Let \( H_{\Gamma} = U \cdot T \) be the real algebraic hull for \( \Gamma \), where \( U \) is the unipotent radical and \( T \) is maximal reductive. Then \( T \) acts by automorphisms on \( U \) and on the cohomology ring \( H^*(u) \). Let \( H^*(u)^T \) denote the \( T \)-invariants in \( H^*(u) \). Let \( M \) be an infra-solvmanifold with fundamental group \( \Gamma \). By Theorem 1.8, \( M \) is diffeomorphic to the standard \( \Gamma \)-manifold \( M_{\Gamma} \). Hence, the following result computes the cohomology of \( M \):

**Theorem 1.8** Let \( M_{\Gamma} \) be a standard \( \Gamma \)-manifold. Then the de Rham-cohomology ring \( H^*(M_{\Gamma}) \) is isomorphic to \( H^*(u)^T \).

We remark that the theorem implies that the discrete group cohomology of \( \Gamma \), \( H^*(\Gamma, \mathbb{R}) = H^*(M_{\Gamma}) \), is isomorphic to the rational cohomology (see [16] Theorem 5.2) of the real linear algebraic group \( H_{\Gamma} \).

Some historical remarks We want to give a few more historical remarks about the context of our paper, and the techniques we use. As our main tool we employ the algebraic hull functor which naturally associates a linear algebraic group to a (torsion-free) virtually polycyclic group or to a solvable Lie group. This functor was considered by Mostow in his paper [26]. Auslander and Tolimieri solved the main open problems on solv-manifolds at their time using the technique of the nilpotent shadow and semi-simple splitting for solvable Lie groups (see [31]). Mostow remarked then in [27] that the nilpotent shadow and splitting construction may be derived naturally from the algebraic hull, and reproved the Auslander-Tolimieri results, as well as his older result on the rigidity of compact solv-manifolds. In our paper, we establish and use the properties of the algebraic hull functor for the class of virtually polycyclic groups not containing finite normal subgroups. We provide the necessary results and proofs about the hull functor in an appendix. Immediate applications are
then our rigidity results and cohomology computations for infra-solvmanifolds. In \[4\] we give another application of the hull functor in the context of affine crystallographic groups and their deformation spaces.

**Arrangement of the paper** We start in §2 with some preliminaries on real algebraic and syndetic hulls for virtually polycyclic groups, affine actions and splittings of real algebraic groups. The necessary results about the construction of algebraic hulls are provided in Appendix A. In §3 we prove Theorem 1.2 and Theorem 1.3. In §4 we provide some applications on the geometry of infrasolvmanifolds. In particular, we show that infra-solvmanifolds are distinguished in the class of aspherical compact differentiable manifolds with a virtually polycyclic fundamental group by the existence of a certain atlas whose coordinate changes are polynomial maps. As an application, we compute the cohomology of infra-solvmanifolds in terms of polynomial differential forms, and derive Theorem 1.8.

**Acknowledgement** I thank Fritz Grunewald, Burkhard Wilking and Wilhem Singhof for helpful comments on an earlier draft of this article.

2 Hulls and splittings

We need some terminology concerning real algebraic groups. For terminology on algebraic groups see also Appendix A. Let \(G\) be a \(\mathbb{R}\)-defined linear algebraic group. The group of real points \(G = G_{\mathbb{R}} \leq \text{GL}_n(\mathbb{R})\) will be called a real algebraic group. The group \(G\) has the natural Euclidean topology which turns it into a real Lie-group but it carries also the Zariski-topology induced from \(G\). Let \(H = H_{\mathbb{R}}\) be another real algebraic group. A group homomorphism \(\phi : G \to H\) is called an algebraic homomorphism if it is the restriction of a \(\mathbb{R}\)-defined morphism \(G \to H\) of linear algebraic groups. If \(\phi\) is an isomorphism of groups which is algebraic with algebraic inverse, then \(\phi\) is called an algebraic isomorphism. We let \(G_0\) denote the Zariski-irreducible component of identity in \(G\), and \(G_0\) the connected component in the Euclidean topology. In particular, \(G_0 \leq G^0\) is a subgroup of finite index in \(G\). If \(g\) is an element of \(G\) then \(g = g_u g_s\) denotes the Jordan-decomposition of \(g\). Here \(g_u \in G\) is unipotent, \(g_s \in G\) is semisimple, and \(g_u, g_s\) commute. Let \(M \subset G\) be a subset. Then \(\overline{M}\) denotes the Zariski-closure of \(M\) in \(G\). We put \(M_u = \{g_u \mid g \in M\}\), \(M_s = \{g_s \mid g \in M\}\). We let \(u(G)\) denote the unipotent radical of \(G\), i.e., the maximal normal subgroup of \(G\) which consists of unipotent elements.

2.1 Solvable by finite real algebraic groups

A linear algebraic group \(H\) is called solvable by finite if \(H^0\) is solvable. Assume that \(H\) is solvable by finite. Then \(H_0 = u(H)\). In particular, for any subgroup \(G\) of \(H\), \(u(G) = G \cap G_u\). If \(G\) is a nilpotent subgroup then (compare, \([7, \S 10]\)) \(G_u\) and \(G_s\) are subgroups of \(H\), and \(G \leq G_u \times G_s\). A Zariski-closed subgroup \(T \leq H\) which consists only of semi-simple elements is called a \(d\)-subgroup of \(H\). The group \(H = H_{\mathbb{R}}\) is called a solvable by finite real algebraic group. Every Zariski-closed subgroup \(T \leq H\) consisting of semi-simple elements is called a
d-subgroup of H. Any d-subgroup of H is an abelian by finite group, and its identity component $T^0$ is a real algebraic torus.

**Proposition 2.1** Let $H$ be a solvable by finite real linear algebraic group. Let $T$ be a maximal d-subgroup of $H$, and $U = u(H)$ the unipotent radical of $H$. Then

$$H = U \cdot T \text{ (semi-direct product)}.$$ 

Moreover, any two maximal d-subgroups $T$ and $T'$ of $H$ are conjugate by an element of $U$.

**Proof.** Let us assume that $H \leq H$ is a Zariski-dense subgroup. Let $T$ be the Zariski-closure of $T$ in $H$. Then $T$ is a $R$-defined subgroup of $H$, and a d-subgroup. Also $T \leq T_R$ and, by maximality of $T$, $T = T_R$. Moreover, $T$ is a maximal reductive $R$-defined subgroup of $H$. Therefore, by a well known result (see [8, Proposition 5.1]) $H = U \cdot T$, where $U = u(H)$, and every two $R$-defined maximal reductive subgroups $T$ and $T'$ are conjugate by an element of $U_R = U$. Then the decomposition of $H$ follows. Since $T$ and $T'$ are the group of real-points in maximal d-subgroups $T$ and $T'$ they are conjugate by an element of $U$. \hfill $\square$

### 2.2 Algebraic hulls

Let $\Gamma$ be a torsion-free virtually polycyclic group. We introduce the concept of an algebraic hull for $\Gamma$. For more details and proofs see Appendix A. Let $G$ be a linear algebraic group, and let $U$ denote the unipotent radical of $G$. We say that $G$ has a **strong unipotent radical** if the centralizer $Z_G(U)$ is contained in $U$.

**Theorem 2.2** There exists a $\mathbb{Q}$-defined linear algebraic group $H$ and an injective homomorphism $\psi: \Gamma \to H_{\mathbb{Q}}$ so that,

- i) $\psi(\Gamma)$ is Zariski-dense in $H$,
- ii) $H$ has a strong unipotent radical $U$,
- iii) $\dim U = \text{rank } \Gamma$.

We call the $\mathbb{Q}$-defined linear algebraic group $H$ the **algebraic hull** for $\Gamma$. The homomorphism $\psi$ may be chosen so that $\psi(\Gamma) \cap H_Z$ has finite index in $\psi(\Gamma)$. Let $k \leq \mathbb{C}$ be a subfield. The hull $H$ together with a Zariski-dense embedding $\psi: \Gamma \to H_k$ of $\Gamma$ into the group of $k$-points of $H$ satisfies the following rigidity property:

$$(*) \text{ Let } H' \text{ be another linear algebraic group and } \psi' : \Gamma \to H'_{\mathbb{Q}} \text{ an injective homomorphism so that i) to iii) above are satisfied with respect to } H' \text{.}$$

Then there exists a $k$-defined isomorphism $\Phi: H \to H'$ so that $\psi' = \Phi \circ \psi$.

In particular, the group $H$ is determined by the conditions i)-iii) up to $\mathbb{Q}$-defined isomorphism of linear algebraic groups.
The real algebraic hull for $\Gamma$ Let $H$ be an algebraic hull for $\Gamma$, $H = H_\mathbb{R}$ the group of real points. Put $U = u(H)$. Then there exists an injective homomorphism $\psi : \Gamma \to H$ which satisfies: i) $\psi(\Gamma) \leq H$ is a discrete, Zariski-dense subgroup, ii) $H$ has a strong unipotent radical, and iii) $\dim U = \text{rank} \, \Gamma$. Let $H' = H'_\mathbb{R}$ be another real linear algebraic group, $\psi' : \Gamma \to H'$ an embedding of $\Gamma$ into $H'$ so that i) to iii) are satisfied with respect to $H'$. Hence, as a consequence of the rigidity property (*), there exists an algebraic isomorphism $\Phi : H \to H'$ so that $\psi' = \Phi \circ \psi$. We call the solvable by finite real linear algebraic group $H_T := H$ the real algebraic hull for $\Gamma$.

The real algebraic hull for $G$ Let $G$ be a connected, simply connected solvable Lie-group. By [30] Proposition 4.40, there exists an algebraic hull for $G$. This means that there exists an $\mathbb{R}$-defined linear algebraic group $H_G$, and an injective Lie-homomorphism $\psi : G \to (H_G)_{\mathbb{R}}$ so that i) $\psi(G) \leq H_G$ is a Zariski-dense subgroup, ii) $H_G$ has a strong unipotent radical $U$, and iii) $\dim U = \dim G$. Moreover, $H_G$ satisfies rigidity properties analogous to the rigidity properties of $H_T$. Let $H_G = (H_G)_\mathbb{R}$. Then there exists a continuous injective homomorphism $\psi : G \to H_G$ which has Zariski-dense image in $H_G$. As for real hulls of discrete groups, these data are uniquely defined up to composition with an isomorphism of real algebraic groups, and we call $H_G$ the real algebraic hull for $G$. We consider henceforth a fixed continuous Zariski-dense inclusion $G \leq H_G$.

Let $N$ denote the nilpotent radical of $G$, i.e., the maximal, connected nilpotent normal subgroup of $G$, and let $U_G$ denote the unipotent radical of $H_G$. Then (compare the proof of Lemma 4.40) $N \leq U_G = u(H_G)$, so that $N$ is the connected component of $u(G) = G \cap u(H_G)$. We remark further that $G$ is a normal subgroup of $H_G$. In fact, $N \leq U_G$ is Zariski-closed in $H_G$, and $[G, G] \leq N$ implies therefore that $[H_G, H_G] \leq N$. Let $T$ be a maximal $d$-subgroup of $H_G$. We consider the decomposition $H_G = U_G : T$. Since $H_G$ is decomposed as a product of varieties, the projection map $\tau_T : H_G \to U_G$, $g = ut \mapsto u$, onto the first factor of the splitting is an algebraic morphism.

**Proposition 2.3** Let $G$ be connected, simply connected solvable Lie group, and $G \leq H_G$ a continuous, Zariski-dense inclusion into its real algebraic hull. Then $G$ is a closed normal subgroup of $H_G$. Moreover, if $T \leq H_G$ is a maximal $d$-subgroup then

$$H_G = GT \, , \, G \cap T = \{1\}.$$ Let $U_G = u(H_G)$ denote the unipotent radical of $H_G$. Then the algebraic projection map $\tau_T : H_G \to U_G$ restricts to a diffeomorphism $\tau : G \to U_G$.

**Proof.** Let $C$ be a Cartan subgroup of $G$. Then $C$ is nilpotent, and $G = NC$, where $N \leq U_G$ is the nilradical of $G$. Let us put $S = C_s = \{g_s \mid g \in C\}$, so that $C \leq C_u \times S$. Note that $C_u$ is a closed subgroup of $U_G$, and $S$ is an abelian subgroup of $H_G$, which is centralizes by $C$. Let $T \leq H_G$ be a maximal $d$-subgroup which contains $S$. Since $H_G = G \leq NC_u T$, we conclude that $U_G = NC_u$ and $H_G = GT$. It follows that the crossed homomorphism $\tau : G \to U_G$ is surjective, in fact, since $\dim U_G = \dim G$ it is a covering map. Since $U_G$ is simply connected $\tau$ must be a diffeomorphism. Therefore $T \cap G = \{1\}$. From the above remarks, $G$ is a normal subgroup of $H_G$. Let $\pi_T : H_G \to T$ denote the projection map onto the second factor of the splitting $H_G = U_G : T$. Then
\[ G = \{ g = u\theta(u) \mid u \in U_G \}, \text{ where } \theta = \pi_T \tau^{-1} : U \to T \text{ is a differentiable map.} \]

Therefore \( G \) is a closed subgroup. \( \square \)

Let \( \Gamma \leq G \) be a lattice. We call \( \Gamma \) a Zariski-dense lattice if \( \Gamma \) is Zariski-dense in \( H_G \). We remark:

**Proposition 2.4** Let \( G \) be a connected, simply connected solvable Lie group, and \( \Gamma \leq G \) a Zariski-dense lattice. Then the real algebraic hull \( H_G \) is a real algebraic hull for \( \Gamma \).

**Proof.** By the inclusion \( \Gamma \leq G \) we have an inclusion \( \Gamma \leq H_G \). Since \( \Gamma \) is cocompact, \( \text{rank } \Gamma = \dim G = \dim u(H_G) \). Therefore \( H_G \) is a \( \mathbb{R} \)-defined algebraic hull for \( \Gamma \). By the rigidity property (*), there exists an \( \mathbb{R} \)-defined isomorphism \( H_\Gamma \to H_G \). In particular, there is an induced algebraic isomorphism of the groups of real points \( H_\Gamma \) and \( H_G \). \( \square \)

Identifying, \( \text{Aut}(G) \) with \( \text{Aut}(\mathfrak{g}) \), where \( \mathfrak{g} \) is the Lie-algebra of \( G \), we obtain a natural structure of real linear algebraic group on \( \text{Aut}(G) \). Let \( H \) be a solvable by finite linear algebraic group, and let \( \text{Aut}_a(H) \) denote its group of algebraic automorphisms. In [17], it is observed that the group \( \text{Aut}_a(H) \) is itself a linear algebraic group if \( H \) has a strong unipotent radical. In particular, \( \text{Aut}_a(H_G) \), the group of algebraic automorphisms of \( H_G \), inherits a structure of a real linear algebraic group. The rigidity of the hull \( H_G \) induces an extension homomorphism

\[ \mathcal{E} : \text{Aut}(G) \hookrightarrow \text{Aut}_a(H_G), \psi \mapsto \Psi. \]

**Proposition 2.5** The extension homomorphism \( \mathcal{E} : \text{Aut}(G) \hookrightarrow \text{Aut}_a(H_G) \) identifies the real linear algebraic group \( \text{Aut}(G) \) with a Zariski-closed subgroup of \( \text{Aut}_a(H_G) \).

**Proof.** Let \( \mathfrak{h}_G \) denote the Lie-Algebra of \( H_G \). From the inclusion \( G \leq H_G \), we have that \( \mathfrak{g} \subseteq \mathfrak{h}_G \). Since \( H_G = H_G^0 \), it follows from the discussion in [17] §3 that the Lie-functor identifies the group \( \text{Aut}_a(H_G) \) with a Zariski-closed subgroup \( \text{Aut}_a(\mathfrak{h}_G) \) of \( \text{Aut}(\mathfrak{h}_G) \). Consider

\[ \text{Aut}_a(\mathfrak{h}_G, \mathfrak{g}) = \text{Aut}_a(\mathfrak{h}_G) \cap \{ \varphi \mid \varphi(\mathfrak{g}) \subseteq \mathfrak{g} \}. \]

The rigidity property of the hull implies that the restriction map

\[ \text{Aut}_a(\mathfrak{h}_G, \mathfrak{g}) \to \text{Aut}(\mathfrak{g}) \]

is surjective. Since \( G \leq H_G \) is Zariski-dense, the restriction map is injective as well. This implies that the restriction map induces an isomorphism of real linear algebraic groups. Since the image of \( \text{Aut}(G) \) in \( \text{Aut}_a(H_G) \) corresponds to the Zariski-closed subgroup \( \text{Aut}_a(\mathfrak{h}_G, \mathfrak{g}) \leq \text{Aut}_a(\mathfrak{h}_G) \), the proposition follows. \( \square \)

### 2.3 Affine actions by rational maps

Let \( G \) be a group. We view the affine group \( \text{Aff}(G) \) as a group of transformations acting on \( G \) by declaring

\[ (g, \phi) \cdot g' = g \phi(g'), \quad \text{where } (g, \phi) \in \text{Aff}(G), \ g' \in G. \]
Let $H$ be a solvable by finite real linear algebraic group with a strong unipotent radical. Let $\text{Aut}_a(H) \leq \text{Aut}(H)$ denote its group of algebraic automorphisms. We remark that, since $H$ has a strong unipotent radical, $\text{Aut}_a(H)$ is a real linear algebraic group (as follows from [17 §4]), and so is
\[ \text{Aff}_a(H) = H \rtimes \text{Aut}_a(H). \]

Let $T$ be a maximal $d$-subgroup of $H$, and $U = u(H)$. For $h \in H$, let $c(h) : H \to H$ denote the inner automorphism $l \mapsto h lh^{-1}$ of $H$. If $L \leq H$ is a normal subgroup $c_L(h)$ denotes the restriction of $c(h)$ on $L$. Let $h = ut$ be a decomposition of $h \in H$ with respect to the algebraic splitting $H = U \cdot T$. Then we have a homomorphism of real algebraic groups
\[ \alpha_T : H \to \text{Aff}_a(U), \quad h = ut \mapsto (u, c_U(t)). \]

Since $H$ has a strong unipotent radical, the homomorphism $\alpha_T$ is injective. Similarly, if $G \leq H$ is a normal subgroup of $H$, $H = GT$ and $G \cap T = \{1\}$, we define
\[ \beta_T : H \to \text{Aff}(G), \quad h = gt \mapsto (g, c_G(t)). \]

**Lemma 2.6** Let $H$ be a solvable by finite real algebraic group with a strong unipotent radical $U$, and let $T \leq H$ be a maximal $d$-subgroup. Assume there exists a connected Lie subgroup $G$ of $H$ which is normal in $H$, so that $H = GT$, $H \cap T = \{1\}$. Then $\beta_T : H \to \text{Aff}(G)$ is an injective continuous homomorphism. Moreover, the projection $\tau : G \to U$, induced by the splitting $H = U \cdot T$, is a diffeomorphism which is equivariant with respect to the affine actions $\beta_T$ and $\alpha_T$.

**Proof.** We remark first that $H = GT$ implies that the Zariski-closure $\overline{G} \leq H$ contains the unipotent radical $U$ of $H$. The argument given in the proof of Proposition 2.3 shows that $\tau$ is a diffeomorphism. Using the notation in the paper, we can write
\[ \beta_T(h) = (\tau_T(h)\theta(\tau_T(h)), c_G(\theta(\tau_T(h))^{-1}\pi_T(h))). \]

This shows that $\beta_T$ is continuous. It is also injective: Assume that $\beta_T(gt) = 1$. Then, in particular, $c_G(t) = \text{id}_G$. Hence, $t$ centralizes the unipotent radical $U$. Since $t$ is semisimple and $H$ has a strong unipotent radical, this implies $t = 1$. Therefore, $h \in G$. But $\beta_T$ is clearly injective on $G$, proving that $\beta_T$ is injective. Finally, let $h \in H$, $g \in G$. Then an elementary calculation shows that $\tau(\beta_T(h) \cdot g) = \alpha_T(h) \cdot \tau(g)$, proving that $\tau$ is equivariant. \(\Box\)

Finally, we briefly remark how the affine action $\alpha_T$ depends on the choice of maximal $d$-subgroup in $H_T$. Let $T' \leq H_T$ be another maximal $d$-subgroup. By Proposition 2.1 there exists $v \in U$ so that $T' = vTv^{-1}$. Let $h = ut$, where $u \in U$, $t \in T$. The decomposition $h = u't'$ of $h$ relative to $T'$ is given by $u' = uu'v^{-1}$, $t' = tv$. Hence,

**Lemma 2.7** Let $R_v : U \to U$ denote right-multiplication with $v$ on $U$, and $T' = vTv^{-1}$. Then, for all $h \in H$, $\alpha_T(h) \circ R_v = R_v \circ \alpha_{T'}(h)$.

2.4 Syndetic hulls

The notion of syndetic hull of a solvable subgroup of a linear group is due to Fried and Goldman, cf. [14 §1.6]. Fried and Goldman introduced this notion in the context of affine crystallographic groups. We will employ the syndetic hull to prove that standard Γ-manifolds are infra-solvmanifolds. We use the slightly modified definition for the syndetic hull which is given in [18]. Let V be a finite-dimensional real vector space.

Definition 2.8 Let Γ be a polycyclic subgroup of GL(V), and G a closed, connected subgroup of GL(V) such that Γ ≤ G. G is called a syndetic hull of Γ if Γ is a Zariski-dense (i.e., G ≤ Γ) uniform lattice in G, and dim G = rank Γ.

The syndetic hull for Γ is necessarily a connected, simply connected solvable Lie group. If Γ ≤ GL(V) is discrete, Γ ≤ (Γ)0, and Γ/u(Γ) is torsion-free then it is proved in [18 Proposition 4.1, Lemma 4.2] that Γ has a syndetic hull. In particular, any virtually polycyclic linear group has a normal finite index subgroup which possesses a syndetic hull. We need the following slightly refined result:

Proposition 2.9 Let H ≤ GL(V) be a Zariski-closed subgroup. Let Δ ≤ H be a virtually polycyclic discrete subgroup, Zariski-dense in H. Then there exists a finite index normal subgroup Γ0 ≤ Δ, and a syndetic hull G for Γ0, Γ0 ≤ G ≤ H, so that G is normalized by Δ.

A similar result is also stated in [14 §1.6]. However, the proof given in [14] is faulty. We refine the proof of [18 Proposition 4.1] a little to obtain Proposition 2.9. Also we warn the reader that a syndetic hull Γ ≤ G is (in general) not uniquely determined by Γ, neither a good syndetic hull (cf. [18]) is uniquely determined by Γ. (See [18 §9].)

Proof of Proposition 2.9 There exists a normal polycyclic subgroup Γ ≤ Δ of finite index with the following properties: Γ ≤ H0, [Γ, Γ] ≤ u(H), and Γ/u(Γ) is torsion-free. We consider the abelian by finite Lie group T = H/N, where N = [Γ, Γ]. Let p : H → T denote the projection, and π : ˆE → T the universal cover. Then ˆE is an extension of a vector space E by some finite group μ. Let ˆS = π−1(ΔN/N), S = ˆS ∩ E. Then μ = ˆS/S. Now K = ker π ⊂ S is invariant by the induced action of μ on S. From Maschke’s theorem we deduce that there exists a μ-invariant complement P ⊂ S of K so that KP is of finite index in S.

Now define ˆP to be the real vector space spanned by P, G = p−1(π( ˆP)), and Γ0 = G ∩ Γ. Then Γ0 is of finite index in Γ, and G is a syndetic hull for Γ0 in the sense of Definition 2.8. Since ˆP is invariant by μ the Lie group G is normalized by Δ.

3 Standard Γ-manifolds

Let Γ be a torsion-free virtually polycyclic group. The purpose of this section is to explain the construction of standard Γ-manifolds and to prove Theorem 1.2 and Theorem 1.3.
3.1 Construction of standard $\Gamma$-manifolds

Let $H_\Gamma$ be a real algebraic hull for $\Gamma$, and fix a Zariski-dense embedding $\Gamma \leq H_\Gamma$. Let $T$ be a maximal $d$-subgroup of $H_\Gamma$, and put $U = u(H_\Gamma)$ for the unipotent radical of $H_\Gamma$. We consider the affine action $\alpha_T : H_\Gamma \to \text{Aff}_a(U)$ which is defined by the splitting $H_\Gamma = U \cdot T$. Since $U$ is strong in $H_\Gamma$, the homomorphism $\alpha_T$ is injective. Let

$$M_{\Gamma, \alpha_T} = \alpha_T(\Gamma) \setminus U$$

denote the quotient space of the affine action of $\Gamma$ on $U$. We will show that $M_{\Gamma, \alpha_T}$ is a compact manifold with fundamental group isomorphic to $\Gamma$. In fact, the proof implies that $M_{\Gamma, \alpha_T}$ is an infra-solvmanifold. We also show that the diffeomorphism class of $M_{\Gamma, \alpha_T}$ depends only on $\Gamma$, not on the choice of maximal $d$-subgroup $T$ in $H_\Gamma$, nor on the particular embedding of $\Gamma$ into $H_\Gamma$. In fact, we show that the corresponding actions of $\Gamma$ are affinely conjugate. We call $M_\Gamma = M_{\Gamma, \alpha_T}$ a standard $\Gamma$-manifold.

**Proof of Theorem 1.2**

We show first that $M_\Gamma$ is an infra-solvmanifold. Let $\Gamma_0$ be a finite index normal subgroup of $\Gamma$ so that there exists a syndetic hull $\Gamma_0 \leq G \leq H_\Gamma$ for $\Gamma_0$. By Proposition 2.4, we may also assume that $G$ is normalized by $\Gamma$. By the defining properties of the hull, $(H_\Gamma)^0$ is a real algebraic hull for $G$. Since $G$ is a normal subgroup in its hull, it follows that $G$ is a normal subgroup of $H_\Gamma = \Gamma(H_\Gamma)^0$. Let $T$ be a maximal $d$-subgroup of $H_\Gamma$. We infer from Proposition 2.6 that $H_\Gamma = GT$, $G \cap T = \{1\}$. Let $\beta_\tau : H_\Gamma \to \text{Aff}(G)$ denote the affine action which is defined by this splitting. Lemma 2.6 implies that the affine action $\beta_\tau$ is effective. Note that $\beta_\tau(\Gamma) \cap G$ contains $\Gamma_0$, hence $\beta_\tau(\Gamma)$ is discrete in $\text{Aff}(G)$ and $\text{hol}(\beta_\tau(\Gamma)) \leq \text{Aut}(G)$ is finite. Therefore, the quotient space

$$M_{\beta_\tau} = \beta_\tau(\Gamma) \setminus G$$

is an infra-solvmanifold. Since $G$ is diffeomorphic to $\mathbb{R}^n$, the fundamental group $\pi_1(M_{\beta_\tau})$ is isomorphic to $\Gamma$. Since $G$ is a syndetic hull, $M_{\beta_\tau}$ is compact. Let $\tau : G \to U$ be the projection map which is induced by the splitting $H_\Gamma = U \cdot T$. By Lemma 2.6, $\tau$ induces a diffeomorphism $\tilde{\tau} : \beta_\tau(\Gamma) \setminus G \to \alpha_T(\Gamma) \setminus U$. Hence $\alpha_T(\Gamma) \setminus U$ is diffeomorphic to a compact infra-solvmanifold.

Note that the diffeomorphism class of $M_\Gamma$ does not depend on the choice of maximal $d$-subgroup in $H_\Gamma$. In fact, let $T' \leq H_\Gamma$ be another maximal $d$-subgroup. Then, by Proposition 2.1, there exists $v \in U$ so that $T' = vTv^{-1}$. By Lemma 2.6, $R_v : U \to U$ induces a smooth diffeomorphism $M_{\Gamma, \alpha_T} \to M_{T', \alpha_T}$. The diffeomorphism class of $M_\Gamma$ is also independent of the particular choice of Zariski-dense embedding of $\Gamma$ into $H_\Gamma$. Let $\Gamma' \leq H_\Gamma$ be a Zariski dense subgroup isomorphic to $\Gamma$, and let $\phi : \Gamma \to \Gamma'$ be an isomorphism. By the rigidity of the real algebraic hull, there exists an algebraic automorphism $\phi : H_\Gamma \to H_\Gamma$ extending $\phi$. The restriction of $\phi$ on the unipotent radical $U$ of $H_\Gamma$ projects to a diffeomorphism $M_{\Gamma, \alpha_T} \to M_{\Gamma', \alpha_T}$ which induces $\phi$ on the level of fundamental groups. Similarly, any given automorphism of $\pi_1(M_{\Gamma, \alpha_T})$ corresponds to an automorphism $\phi$ of $\Gamma$. The algebraic extension $\tilde{\phi}$ projects to a diffeomorphism of $M_{\Gamma, \alpha_T}$ inducing $\phi$ on $\pi_1(M_{\Gamma, \alpha_T})$.

We also remark:

**Proposition 3.1** Every standard $\Gamma$-manifold $M_\Gamma$ admits a smooth effective action of an $r$-dimensional torus $T^r$, where $r = \text{rank} \mathbb{Z}(\Gamma)$.
Proof. Let $U_Z = \overline{Z(\Gamma)}$ be the Zariski-closure of $Z(\Gamma)$ in $H_\Gamma$. Since $U_Z \leq Z(H_\Gamma)$, $U_Z \leq U$, and $\dim U_Z = r$. It follows that $\alpha_T(U_Z)$ induces a free maximal torus action on $M_\Gamma$. \qed

Theorems 1.4 and Proposition 3.1 imply Corollary 1.7.

3.2 Affine actions on unipotent groups

Here we show that every compact manifold which arises by (solvable by finite) affine actions on unipotent groups is diffeomorphic to a standard $\Gamma$-manifold.

Proposition 3.2 Let $U$ be a connected, simply connected nilpotent Lie group. Let $\Delta \leq \text{Aff}(U)$ be a solvable by finite subgroup which acts freely and properly on $U$ with compact quotient manifold $M = \Delta \backslash U$. Let $T \leq \overline{\Delta} \leq \text{Aff}(U)$ be a maximal $d$-subgroup. Then $M$ is diffeomorphic to $\alpha_T(\Delta) \backslash u(\Delta)$.

Proof. We decompose $\overline{\Delta} = u(\overline{\Delta}) T$. Since any maximal $d$-subgroup of $\text{Aut}(U)$ is maximal in $\text{Aff}(U)$, we may assume (after conjugation of $\Delta$ with a suitable element of $\text{Aff}(U)$) that $T \leq \text{Aut}(U)$. In particular, $\overline{\Delta} \cdot 1 = u(\overline{\Delta}) \cdot 1$, and hence $\Delta$ acts on the orbit $O = u(\overline{\Delta}) \cdot 1 \leq U$. Since $O$ is the homogeneous space of a connected unipotent group acting on $U$, it is a submanifold diffeomorphic to $\mathbb{R}^k$, $k \leq \dim U$. The connected, simply connected solvable Lie group $\Delta_0$ acts freely on $O$, and the quotient space $\Delta_0 \backslash O$ is a simply connected aspherical manifold. Hence, the quotient space $M_O = \Delta \backslash O$ is a manifold with fundamental group isomorphic to $\Gamma$, and homotopy equivalent to an Eilenberg-Mac Lane space $K(\Gamma, 1)$. Since $M$ is an aspherical compact manifold with fundamental group $\Gamma$, its dimension equals the cohomological dimension of $\Gamma$. This implies that $\dim M \leq \dim M_O$, and consequently $O = U$. In particular, $u(\overline{\Delta})$ acts transitively on $U$ and the orbit map

$$o : u(\overline{\Delta}) \to U, \quad \delta \mapsto \delta \cdot 1$$

in $1 \in U$ is a diffeomorphism. Using $T \leq \text{Aut}(U)$, it is straightforward to verify that $o$ is $\Delta$-equivariant with respect to the affine action $\alpha_T$ of $\Delta$ on $u(\overline{\Delta})$. Hence, $M$ is diffeomorphic to $\alpha_T(\Delta) \backslash u(\overline{\Delta})$. \qed

The next result shows how the algebraic hull enters the picture:

Proposition 3.3 Let $\Gamma \leq \text{Aff}(U)$ be virtually polycyclic, such that $\Gamma$ acts freely and properly discontinuously on $U$, and with compact quotient $M = \Gamma \backslash U$. Then the Zariski-closure $\overline{\Gamma} \leq \text{Aff}(U)$ is an algebraic hull for $\Gamma$. In particular, $M$ is diffeomorphic to a standard $\Gamma$-manifold.

Proof. Put $H = \overline{\Gamma} \leq \text{Aff}(U)$. By the previous proposition, the orbit map $o : u(H) \to U$ in $1 \in U$ is a diffeomorphism. In particular, $\dim u(H) = \text{rank} \Gamma$. Let $T \leq H$ be a maximal $d$-subgroup. We may assume that $T \leq \text{Aut}(U)$. This shows that $T \cap Z_H(U) = \{1\}$. Hence, $H$ has a strong unipotent radical. It follows that $H$ is an algebraic hull for $\Gamma$. Since $o$ is equivariant with respect to the action $\alpha_T$, $M$ is diffeomorphic to a standard $\Gamma$-manifold. \qed

Next we consider affine actions which arise from splittings of solvable by finite linear algebraic groups.
**Proposition 3.4** Let $H = UT$ be a solvable linear algebraic group. Let $\Theta \leq H$ be a Zariski-dense subgroup such that $\Delta = \alpha_T(\Theta) \leq \text{Aff}(U)$ acts freely and properly on $U$ with compact quotient manifold $M = \Delta \backslash U$. Then $\Gamma = \Delta/\Delta_0$ is virtually polycyclic and $M$ is diffeomorphic to a standard $\Gamma$-manifold.

**Proof.** Put $U_{\Delta_0} = u(\overline{\Delta_0})$, and remark that $U_{\Delta_0} \leq U$ under the natural inclusion $U \leq \text{Aff}(U)$. Since $\Delta_0$ is normal in $\Delta$, $U_{\Delta_0}$ is normal in $\overline{\Delta}$. From $\overline{\Delta_0} \cdot 1 = U_{\Delta_0} \cdot 1$ and $\dim u(\overline{\Delta_0}) \leq \dim \Delta_0$, we deduce that $\Delta_0 \cdot 1 = U_{\Delta_0} \cdot 1$ and also that $\dim \Delta_0 = \dim U_{\Delta_0}$. Let $h \in \Theta$, such that $\alpha_T(h) \in \Delta_0$. Then $h = utu^{-1}$, where $u_h \in U_{\Delta_0}$ and $t \in T$. Moreover,

$$\alpha_T(h) \cdot u = u_h utu^{-1} = u_h(tut^{-1}u^{-1})u.$$ 

Remark that $\overline{\Delta_0}$ and $U_{\Delta_0}$ are normal in $\alpha_T(H)$. This implies that $h^u = vt$, where $v \in U_{\Delta_0}$, $v = (u_h u) (utu^{-1}t^{-1})$. Furthermore $u_h u^{-1} \in U_{\Delta_0}$, and consequently $u h u^{-1} \in U_{\Delta_0}$. Since $\Delta_0$ acts freely, this implies that $\Delta_0 \cdot u = u(\overline{\Delta_0}) \cdot u$. Hence, $\Delta_0$, and $U_{\Delta_0}$ have the same orbits on $U$.

Put $L = H/U_{\Delta_0}$, and $U_L = U/U_{\Delta_0}$. Let $\pi : H \to L$ be the quotient homomorphism. Put $\Upsilon := \pi(\Theta)$. Then $\Upsilon$ is a Zariski-dense subgroup of $L$. Decompose $L = U_L \pi(T)$. Evidently, $\pi$ induces a diffeomorphism of quotient spaces $\alpha_T(\Theta)/U \to \alpha_{\pi(T)}(\Upsilon)/U_L$. In particular, $M$ is diffeomorphic to $\alpha_{\pi(T)}(\Upsilon)/U_L$. Moreover, $\alpha_{\pi(T)}(\Upsilon)$ is a discrete solvable subgroup of $\text{Aff}(U_L)$ and isomorphic to $\Delta/\Delta_0$. Since $\text{Aff}(U_L)$ has only finitely many connected components, a theorem of Mostow $\dagger$ implies that $\Gamma = \Delta/\Delta_0$ is virtually polycyclic. By Proposition $\dagger$ $M$ is diffeomorphic to a standard $\Gamma$-manifold.

Putting the results together, we proved:

**Theorem 3.5** Let $U$ be connected, simply connected nilpotent Lie group. Let $\Delta \leq \text{Aff}(U)$ be a solvable by finite subgroup which acts freely and properly on $U$ with compact quotient manifold $M = \Delta \backslash U$. Then $\Gamma = \Delta/\Delta_0$ is virtually polycyclic, and $M$ is diffeomorphic to a standard $\Gamma$-manifold.

### 3.3 Rigidity of reductive affine actions

Let $G$ be a connected, simply connected solvable Lie group and $\Delta \leq \text{Aff}(G)$ a solvable by finite subgroup which acts on $G$. Let $H_G$ be an algebraic hull for $G$, and fix a Zariski-dense continuous inclusion $G \leq H_G$. By the rigidity of the hull, there are induced inclusions $\text{hol}(\Delta) \leq \text{Aut}_o(H_G)$, and $\Delta \leq \text{Aff}_o(H_G)$. Let $T \leq H_G$ be a maximal $d$-subgroup, and $U_G$ the unipotent radical of $H_G$. Then, $G$ acts affinely on $U_G$ via the action $\alpha_T$, c.f. [23]. Note that the orbit map of this action in $1 \in U_G$, $\alpha_T : G \to U_G$, coincides with the projection diffeomorphism $\tau : G \to U_G$. Via $\alpha_T$, the affine action of $\Delta$ on $G$ induces then a diffeomorphic action of $\Delta$ on $U_G$.

**Lemma 3.6** Suppose that $\text{hol}(\Delta) \leq \text{Aut}_o(H_G)$ stabilizes $T$. Then the action of $\Delta$ on $U_G$ induced by the orbit map $\alpha_T : G \to U_G$ is affine.

**Proof.** A straightforward computation shows that the lemma is true: Let $\delta = (h, \phi) \in \text{Aff}(G)$, where $h \in G$, $\phi \in \text{hol}(\Delta)$. We consider $\phi$ henceforth as an element of $\text{Aut}(H_G)$. Write $h = u_h t_h$, where $u_h \in U_G$, $t_h \in T$. Analogously,
write $g = u_g t_g$, for $g \in G$. Now, $\delta \cdot g = h\phi(g) = u_h t_h \phi(u_g) \phi(t_g)$. By our assumption, $\phi(t_g) \in T$. Hence,

$$
\sigma_T(\delta \cdot g) = \tau(u_h \phi(u_g)^{t_h} t_h \phi(t_g)) = u_h \phi(u_g)^{t_h} \\
= \alpha_T(h) \cdot \phi(u_g) = (\alpha_T(h) \circ \phi) \cdot \sigma_T(g).
$$

Therefore, the action of $\delta$ on $G$, corresponds to the action of $\alpha_T(h) \circ \phi$ on $U_G$.

Lemma 3.7 Let $L \leq \text{Aut}_a(H_G)$ be a reductive subgroup. Then $L$ stabilizes a maximal torus $T \leq H_G$.

Proof. Consider the semi-direct product $H_L = H_G \rtimes L$. Then $u(H_L) = U_G$ is the unipotent radical of $H_L$. Let $S$ be a maximal reductive subgroup in $H_L$ which contains $L$ such that $H_L = U_G S$. Then $T = S \cap H_G$ is a d-subgroup in $H_G$ which is normalized by $L$, and $S = T L$. The latter equality shows that $H_G = U_G T$ and therefore $T$ is a maximal torus of $H_G$. \qed

In the light of Theorem 3.5, Lemma 3.6 and Lemma 3.7 prove the following:

Theorem 3.8 Let $\Delta \leq \text{Aff}(G)$ act freely on $M$ with quotient space $\Delta \bs G$ a compact manifold. Assume further that $\text{hol}(\Delta) \leq \text{Aut}_a(H_G)$ is contained in a reductive subgroup of $\text{Aut}_a(H_G)$. Then $M = \Delta \bs G$ is diffeomorphic to a standard $\Gamma$-manifold.

Theorem 3.8 implies part ii) of Theorem 1.3. In fact, by Proposition 2.5 the assumption ii) implies that $\text{hol}(\Delta)$ is contained in a reductive subgroup of $\text{Aut}_a(H_G)$. In particular, condition ii) is satisfied if the Zariski-closure of $\text{hol}(\Delta)$ in $\text{Aut}(G)$ is compact. This proves then Theorem 1.4.

4 Geometry of infra-solvmanifolds

We derive a few consequences of our proof which concern the existence and uniqueness of certain geometric structures on infra-solvmanifolds. As another application we construct a finite-dimensional complex which computes the cohomology of an infra-solvmanifold.

4.1 Infra-solv geometry

Let $M$ be a compact infra-solvmanifold. A pair $(G, \Delta)$, $\Delta \subset \text{Aff}(G)$, so that $M$ is diffeomorphic to $\Delta \bs G$ is called a presentation for $M$. By the proof of Theorem 1.2, every standard $\Gamma$-manifold admits a presentation $(G, \Gamma)$ so that $\Gamma \leq \text{Aff}(G)$ is discrete with finite holonomy group $\text{hol}(\Gamma)$. Hence, by Theorem 1.4, every compact infra-solvmanifold has such a presentation. (The appendix of [13] is devoted to proving that every infra-solvmanifold has a presentation with finite holonomy.)

Corollary 4.1 Every compact infra-solvmanifold $M$ admits a discrete presentation with finite holonomy.
Let \((G, \Gamma)\) be a discrete presentation for \(M\) with finite holonomy. Then \(M\) is finitely covered by the homogeneous space \(\Gamma \cap G\backslash G\) of the solvable Lie-group \(G\). The group \(G\) carries a natural flat (but not necessarily torsion-free) left invariant connection which is preserved by \(\text{Aff}(G)\). Since the presentation is discrete, \(M\) has a flat connection inherited from \(G\). The group of covering transformations of \(\Gamma \cap G\backslash G \to M\) is acting by connection preserving diffeomorphisms. This geometric property distinguishes infra-solvmanifolds from the larger class of compact manifolds which admit a finite covering by a solv-manifold. (Compare also [32] for a similar discussion.) One should note however that the Lie group \(G\), and discrete presentation \((G, \Gamma)\) is not uniquely determined by \(M\). However, Wilking [33] proved that every infra-solvmanifold is modelled in a canonical way on an affine isometric action on a super-solvable Lie-group.

Our approach implies that, dropping the condition of finite holonomy, there is a canonical choice of flat geometry on \(M\) which is modelled on a nilpotent Lie group. Let \(U\) be a unipotent real algebraic group, \(\Gamma \leq \text{Aff}(U)\) a discrete subgroup which acts properly discontinuously on \(U\). (It is not required that the holonomy of \(\Gamma\) be finite.) Then \(\Gamma\) preserves the natural flat invariant connection on \(U\), and there is an induced flat connection on the quotient manifold \(M\).

We say that \(M\) has an \textit{affinely flat geometry modelled on} \(U\). Let \(U_\Gamma\) denote the unipotent radical of the real algebraic hull of \(\Gamma\). We call \(U_\Gamma\) the \textit{unipotent shadow of} \(\Gamma\).

**Corollary 4.2** Every compact infra-solvmanifold \(M\) admits an affinely flat geometry modelled on the simply connected nilpotent Lie group \(U_{\pi_1(M)}\).

**Toral affine actions** A natural question is the following: \textit{Given} \(G\) \textit{a simply connected solvable Lie group. Which polycyclic groups act affinely on} \(G\) \textit{with a compact quotient manifold?} In the particular case where \(G\) is abelian, this question asks for the classification of affine crystallographic groups. This is a well known and difficult geometric problem. (Compare [41], and also the references cited therein for some recent results).

Some answers to the above question can be given when putting restrictions on the holonomy. Let us call the holonomy \(\text{hol}(\Gamma) \leq \text{Aut}(G)\) \textit{toral} if the Zariski-closure of \(\text{hol}(\Gamma)\) is a reductive subgroup of \(\text{Aut}(G)\). In particular, \(\text{hol}(\Gamma)\) is toral if its closure is compact. Hence, infra-solvmanifolds come from toral actions. Note that also standard \(\Gamma\)-manifolds are constructed using toral affine actions. Now let \(U_G\) denote the unipotent radical of the real algebraic hull of \(\Gamma\). We call \(U_\Gamma\) the \textit{unipotent shadow of} \(\Gamma\).

**Proposition 4.3** Let \(\Gamma\) be torsion-free virtually polycyclic, acting on the connected, simply connected solvable Lie group \(G\) with compact quotient space and toral holonomy. Then \(U_G = U_\Gamma\).

**Proof.** Let \(T_1\) denote the Zariski-closure of \(\text{hol}(\Delta)\) in \(\text{Aut}_a(H_G)\). By the assumption, \(T_1 \leq \text{Aut}_a(H_G)\) is a \(d\)-subgroup. By Proposition 2.5 \(T_1\) stabilizes \(G\), i.e., \(T_1 \leq \text{Aut}(G)\). Also \(T_1\) stabilizes a maximal torus \(T \leq H_G\). Then the corresponding projection map \(\tau : G \to U_G\) induces an affine action of \(\Gamma\) on \(U_G\). By the proof of Lemma 3.6, the image of \(\Gamma\) in \(\text{Aff}(U_G)\) is contained in \(U_G \rtimes T T_1 \leq \text{Aff}(U_G)\). By Proposition 3.3 the Zariski-closure of \(\Gamma\) in \(U_G \rtimes T T_1\) is an algebraic hull for \(\Gamma\). Hence, \(U_G = U_\Gamma\).

In particular, if \(\Gamma\) acts isometrically on \(G\), then \(U_G = U_\Gamma\).
4.2 Polynomial geometry

The construction of standard $\Gamma$-manifolds was carried out in the category of real algebraic groups. In fact, as noted above such a manifold is obtained as a quotient space $\Gamma \backslash U$, where $U$ is a unipotent real algebraic group, and $\Gamma \leq \text{Aff}_a(U)$ is a properly discontinuous subgroup. In particular, $\Gamma$ acts algebraically on $U$. A differentiable map of $\mathbb{R}^n$ is called a polynomial map if its coordinate functions are polynomials. A polynomial diffeomorphism is a polynomial map which has a polynomial inverse. A group of polynomial diffeomorphisms of $\mathbb{R}^n$ is called bounded if there is a common bound for the degrees of the polynomials which describe its elements. It is known that any algebraic group action on $\mathbb{R}^n$ is bounded. Now, since $U$ is diffeomorphic to $\mathbb{R}^n$, $n = \dim U$, and since the diffeomorphism is given by the exponential map $\exp : u = \mathbb{R}^n \to U$ which actually is an algebraic map, we obtain:

**Corollary 4.4** Every torsion-free virtually polycyclic group $\Gamma$ acts faithfully as a discrete group of bounded polynomial diffeomorphisms on $\mathbb{R}^n$, $n = \text{rank} \Gamma$. The quotient space $\Gamma \backslash \mathbb{R}^n$ is diffeomorphic to a standard $\Gamma$-manifold.

Slightly more general, our proof works for all virtually polycyclic groups which do not have finite normal subgroups (see the Appendix). The existence of such actions was shown previously in [19] by different methods. Recently, it was proved [5] that a bounded polynomial action of $\Gamma$ on $\mathbb{R}^n$ is unique up to conjugation by a bounded polynomial diffeomorphism. Therefore Theorem [14] implies also the following characterization of infra-solvmanifolds.

**Corollary 4.5** Let $M$ be a compact differentiable manifold, aspherical and with a virtually polycyclic fundamental group. Then $M$ is diffeomorphic to an infra-solv manifold if and only if $M$ is diffeomorphic to a quotient space of $\mathbb{R}^n$ by a properly discontinuous bounded group of polynomial diffeomorphisms.

4.3 Polynomial cohomology

Let $M$ be an infra-solvmanifold and fix a diffeomorphism of $M$ to a quotient space $\mathbb{R}^n/\Gamma$, where $\Gamma$ acts as a group of bounded polynomial diffeomorphisms. Recall that a differential form (more generally a tensor field) on $\mathbb{R}^n$ is called polynomial if its component functions relative to the standard coordinate system are polynomials. Since $\Gamma$ acts by polynomial maps, the notion of polynomial differential form on $M$ is well defined. This gives a subcomplex

$$\Omega^*_{\text{poly}}(M) \subset \Omega^*(M)$$

of the $C^\infty$-de Rham complex $\Omega^*(M)$. The following result generalizes a theorem of Goldman [15] on the cohomology of compact complete affine manifolds:

**Theorem 4.6** The induced map on cohomology $H^*_{\text{poly}}(M) \to H^*(M)$ is an isomorphism.

**Proof.** The idea of the proof which is given in [15] carries over to our situation. We pick up the notation of [15]. Let $\Gamma \leq \Gamma_T$, where $\Gamma_T$ is the algebraic hull of $\Gamma$. As explained in section 5 $\Gamma_T$ acts as a subgroup of $\text{Aff}_a(U)$ on $U$. Via $\exp : u \to U$, $\Gamma_T$ acts by polynomial maps on $\mathbb{R}^n = U$. The cohomology of $M$...
is computed by the complex $\Omega^*(\mathbb{R}^n)^\Gamma$ of $\Gamma$-invariant differential forms on $\mathbb{R}^n$. Therefore, we have to show that the inclusion of complexes

$$\Omega^\ast_{\text{poly}}(\mathbb{R}^n)^\Gamma \to \Omega^*(\mathbb{R}^n)^\Gamma$$

induces an isomorphism on cohomology. Let $\Gamma_0$ be a finite index normal subgroup of $\Gamma$ with syndetic hull $G$, so that

$$\Gamma_0 \leq G \leq H = (H_T)_0.$$ 

We consider now the following inclusion maps of complexes

$$\Omega^*(\mathbb{R}^n)^H \to \Omega^*(\mathbb{R}^n)^G \to \Omega^*(\mathbb{R}^n)^{\Gamma_0}.$$ 

Decompose $H = US = GS$, where $S$ is a maximal $d$-subgroup of $H$. By Lemma 2.6, $G$ acts simply transitively on $\mathbb{R}^n$ via the affine action $\alpha_T$ of $H_T$ on $U$. Hence, the complex $\Omega^*(\mathbb{R}^n)^G$ identifies with the complex $H^\ast(g)$ of left invariant differential forms on $G$. The action of $G$ on $H^\ast(g)$ which is induced by conjugation is trivial. Since $G$ is Zariski-dense in $H$, $H$ acts trivially on $H^\ast(g)$. The affine action of $S \leq H$ on $U$ corresponds to conjugation on $G$. It follows that $S$ acts trivially on the cohomology of the complex $\Omega^*(\mathbb{R}^n)^G$. Since $S$ acts reductively on $\Omega^*(\mathbb{R}^n)^G$, this implies

$$H^\ast(\Omega^*(\mathbb{R}^n)^G) = H^\ast(\Omega^*(\mathbb{R}^n)^G)^S = H^\ast(\Omega^*(\mathbb{R}^n)^H).$$

In particular, $\Omega^*(\mathbb{R}^n)^H \to \Omega^*(\mathbb{R}^n)^G$ induces an isomorphism on cohomology. The map $\Omega^*(\mathbb{R}^n)^G \to \Omega^*(\mathbb{R}^n)^{\Gamma_0}$ is an isomorphism on the cohomology level by a theorem of Mostow [27] (see also [30] Corollary 7.29). Hence, the induced map $H^\ast(\Omega^*(\mathbb{R}^n)^H) \to H^\ast(\Omega^*(\mathbb{R}^n)^{\Gamma_0})$ is an isomorphism.

Next remark that $\Omega^*(\mathbb{R}^n)^H = \Omega^\ast_{\text{poly}}(\mathbb{R}^n)^H = \Omega^\ast_{\text{poly}}(\mathbb{R}^n)^{\Gamma_0}$. The first equality follows since every left invariant differential form on $U$ is polynomial relative to the coordinates given by the exponential map. The second equality follows since $\Gamma_0$ is Zariski-dense in $H$. We conclude that the natural map

$$H^\ast(\Omega^\ast_{\text{poly}}(\mathbb{R}^n)^{\Gamma_0}) \to H^\ast(\Omega^*(\mathbb{R}^n)^{\Gamma_0})$$

is an isomorphism. This proves that $H^\ast_{\text{poly}}(M_{\Gamma_0}) = H^\ast(M_{\Gamma_0}).$

Put $\mu = \Gamma/\Gamma_0$. Then $\mu$ acts on the cohomology of $\Omega^*(\mathbb{R}^n)^{\Gamma_0}$. The inclusion map $\Omega^*(\mathbb{R}^n)^\Gamma \to \Omega^*(\mathbb{R}^n)^{\Gamma_0}$ induces an isomorphism on cohomology

$$H^\ast(\Gamma) \to H^\ast(\mu M_{\Gamma_0}).$$

Similarly, $H^\ast_{\text{poly}}(M_{\Gamma_0})^\mu$ is isomorphic to the cohomology of the $\mu$-invariant forms in $\Omega^\ast_{\text{poly}}(\mathbb{R}^n)^{\Gamma_0}$, implying that $H^\ast_{\text{poly}}(M_{\Gamma}) = H^\ast_{\text{poly}}(M_{\Gamma_0})^\mu$. Hence,

$$H^\ast(\mu M_{\Gamma}) = H^\ast(M_{\Gamma}).$$

The theorem follows. 

\begin{proof}[Proof of Theorem 1.5] By the previous theorem, $H^\ast(M_{\Gamma}) = H^\ast_{\text{poly}}(M_{\Gamma})$.

Now

$$H^\ast_{\text{poly}}(M_{\Gamma}) = H^\ast(\Omega^\ast_{\text{poly}}(\mathbb{R}^n)^H).$$

\end{proof}
Let $T$ be a maximal $d$-subgroup of $H$. Since $U$ acts simply transitively on $\mathbb{R}^n$, the complex $\Omega^*_\text{poly}(\mathbb{R}^n)^H$ is isomorphic to the left-invariant forms on $U$ which are fixed by $T$. Let $u$ denote the Lie algebra of $U$. Since $T$ acts reductively on the complex $\Omega^*_\text{poly}(\mathbb{R}^n)^U$, it follows that

$$H^*_\text{poly}(M_\Gamma) = H^*((\Omega^*_\text{poly}(\mathbb{R}^n)^U)^T) = H^*(u)^T.$$ 

\[\square\]

A Algebraic hulls for virtually polycyclic groups

Let $k \leq \mathbb{C}$ be a subfield. A group $G$ is called a $k$-defined linear algebraic group if it is a Zariski-closed subgroup of $\text{GL}_n(\mathbb{C})$ which is defined by polynomials with coefficients in $k$. A morphism of algebraic groups is a morphism of algebraic varieties which is also a group homomorphism. A morphism is defined over $k$ if the polynomials which define it have coefficients in $k$. It is called a $k$-isomorphism if its inverse exists and is a morphism defined over $k$. Let $U = u(G)$ denote the unipotent radical of $G$. We say that $G$ has a strong unipotent radical if the centralizer $Z_G(U)$ is contained in $U$.

A.1 The algebraic hull

Let $\Gamma$ be a virtually polycyclic group. Its maximal nilpotent normal subgroup $\text{Fitt}(\Gamma)$ is called the Fitting subgroup of $\Gamma$. Now assume that $\text{Fitt}(\Gamma)$ is torsion-free and $Z_\Gamma(\text{Fitt}(\Gamma)) \leq \text{Fitt}(\Gamma)$. In this case, we say that $\Gamma$ has a strong Fitting subgroup. We remark (see also Corollary A.9) that this condition is equivalent to the requirement that $\Gamma$ has no non-trivial finite normal subgroups. The following result was announced in [4].

**Theorem A.1** Let $\Gamma$ be a virtually polycyclic group with a strong Fitting subgroup. Then there exists a $\mathbb{Q}$-defined linear algebraic group $H$ and an injective group homomorphism $\psi : \Gamma \rightarrow H^\mathbb{Q}$ so that,

i) $\psi(\Gamma)$ is Zariski-dense in $H$,

ii) $H$ has a strong unipotent radical $U$,

iii) $\dim U = \text{rank } \Gamma$.

Moreover, $\psi(\Gamma) \cap H_\mathbb{Z}$ is of finite index in $\psi(\Gamma)$.

We remark that the group $H$ is determined by the conditions i)-iii) up to $\mathbb{Q}$-isomorphism of algebraic groups:

**Proposition A.2** Let $H'$ be a $\mathbb{Q}$-defined linear algebraic group, $\psi' : \Gamma \rightarrow H'^\mathbb{Q}$ an injective homomorphism which satisfies i) to iii) above. Then there exists a $\mathbb{Q}$-defined isomorphism $\Phi : H \rightarrow H'$ so that $\psi' = \Phi \circ \psi$.

**Corollary A.3** The algebraic hull $H^\Gamma$ of $\Gamma$ is unique up to $\mathbb{Q}$-isomorphism of algebraic groups. In particular, every automorphism $\phi$ of $\Gamma$ extends uniquely to a $\mathbb{Q}$-defined automorphism $\Phi$ of $H^\Gamma$. 

18
We call the \( \mathbb{Q} \)-defined linear algebraic group \( H \) the **algebraic hull for** \( \Gamma \). If \( \Gamma \) is finitely generated torsion-free nilpotent then \( H \) is unipotent and Theorem\ref{a1} and Proposition\ref{a2} are essentially due to Malcev. If \( \Gamma \) is torsion-free polycyclic, Theorem\ref{a1} is due to Mostow \cite{mostow} (see also \cite{bass} §IV, p.74 for a different proof).

### A.2 Construction of the algebraic hull

Let \( \Delta \) be a virtually polycyclic group with \( \text{Fitt}(\Delta) \) torsion-free. Since \( \Delta \) is virtually polycyclic it contains a torsion-free polycyclic subgroup \( \Gamma \) which is normal and of finite index. By Mostow’s theorem there exists an algebraic hull \( \psi_\Gamma : \Gamma \to H_\Gamma \) for \( \Gamma \). Hence, in particular \( \Gamma \) is realized as a subgroup of a linear algebraic group.

**Embedding of finite extensions** We use a standard induction procedure to realize the finite extension group \( \Delta \) of \( \Gamma \) in a linear algebraic group which finitely extends \( H_\Gamma \). The procedure is summarized in the next lemma.

**Lemma A.4** Let \( G \) be a linear algebraic group defined over \( \mathbb{Q} \) and \( \Gamma \leq G_\mathbb{Q} \) a subgroup. Let \( \Delta \) be a finite extension group of \( \Gamma \) so that \( \Delta \) is normal in \( \Gamma \). Let \( \Delta = \Gamma r_1 \cup \cdots \cup \Gamma r_m \) be the decomposition of \( \Delta \) into left cosets, and assume that there are \( \mathbb{Q} \)-defined algebraic group morphisms \( f_1, \ldots, f_m : G \to G \) so that

\[
 f_i(\gamma) = r_i \gamma r_i^{-1}, \quad i = 1, \ldots, m, \quad \text{for all } \gamma \in \Gamma.
\]

Then there exists a \( \mathbb{Q} \)-defined linear algebraic group \( I(G, \Gamma, \Delta) \), an injective homomorphism \( \psi : \Delta \to I(G, \Gamma, \Delta) \) and a \( \mathbb{Q} \)-defined injective morphism of algebraic groups \( \Psi : G \to I(G, \Gamma, \Delta) \) which extends \( \psi : \Gamma \to I(G, \Gamma, \Delta) \) so that \( \psi(\Delta) \leq I(G, \Gamma, \Delta)_\mathbb{Q} \), \( I(G, \Gamma, \Delta) = \Psi(G)\psi(\Delta) \) and \( \Psi(G) \cap \psi(\Delta) = \psi(\Gamma) \).

For more comments and details of the proof see \cite{bass} Proposition 2.2.

**The algebraic hull for** \( \Delta \) We continue with our standing assumption that \( \Delta \) is a virtually polycyclic group with \( \text{Fitt}(\Delta) \) torsion-free and \( \mathbb{Z}_\Delta(\text{Fitt}(\Delta)) \leq \text{Fitt}(\Delta) \). Let \( \Gamma \leq \Delta \) be a torsion-free polycyclic normal subgroup of finite index. By Mostow’s result there exists an algebraic hull \( H_\Gamma \) for \( \Gamma \), and we may assume that \( \Gamma \leq (H_\Gamma)_\mathbb{Q} \) is a Zariski-dense subgroup. Replacing \( \Gamma \) with a finite index subgroup, if necessary, we may also assume that \( H_\Gamma \) is connected.

**Proposition A.5** There exists a \( \mathbb{Q} \)-defined linear algebraic group \( I(H_\Gamma, \Delta) \) which contains \( H_\Gamma \), and an embedding \( \psi : \Delta \to I(H_\Gamma, \Delta)_\mathbb{Q} \) which is the identity on \( \Gamma \), such that \( I(H_\Gamma, \Delta) = H_\Gamma \psi(\Delta) \) and \( \psi(\Delta) \cap H_\Gamma = \psi(\Gamma) \).

**Proof.** Let \( \Delta = \Gamma r_1 \cup \cdots \cup \Gamma r_m \) be a decomposition of \( \Delta \) into left cosets. By the rigidity of the algebraic hull (Proposition\ref{a2}), conjugation with \( r_i \) on \( \Gamma \) extends to \( \mathbb{Q} \)-defined morphisms \( f_i \) of \( H \) which satisfy \( \Pi \). The results follows then from Lemma\ref{a4} putting \( I(H_\Gamma, \Delta) := I(H_\Gamma, \Gamma, \Delta) \).

\( \square \)

We need some more notations. Let \( G \) be an algebraic group. We let \( G^0 \) denote its connected component of identity. If \( g \) is an element of \( G \) then \( g = g_u g_s \) denotes the Jordan-decomposition of \( g \) (i.e., \( g_u \) is unipotent, \( g_s \) is semisimple and \( [g_s, g_u] = 1 \)). If \( M \) is a subset then let \( M_u = \{ g_u \mid g \in M \} \), \( M_s = \{ g_s \mid g \in M \} \).

19
If $G$ is a subgroup then $u(G)$ denotes the unipotent radical of $G$, i.e., the maximal normal subgroup of $G$ which consists of unipotent elements. We will use the following facts (compare, [7 §10]): If $G$ is a nilpotent subgroup then $G_u$ and $G_s$ are subgroups of $G$, and $G \leq G_u \times G_s$. If $G^0$ is solvable then $G_u = u(G)$. In particular, for any subgroup $G$ of $G$, $u(G) = G \cap G_u$.

To construct the algebraic hull for $\Delta$ we have to further refine Proposition A.6.

**Proof of Theorem A.7** Let $U$ denote the unipotent radical of $H_\Gamma$. By Proposition A.3 we may assume that $\Delta \leq G_Q$ is a Zariski-dense subgroup of a $Q$-defined linear algebraic group $G$ so that $G = H_\Gamma \Delta$, $u(G) = U$ and $\Delta \cap H_\Gamma = \Gamma$. Since $H_\Gamma$ is an algebraic hull, $Fitt(\Gamma) \leq U$, see Proposition A.7. Since $Fitt(\Gamma)$ is a subgroup of finite index in $Fitt(\Delta)$ the group $\mu = \{\gamma_s \mid \gamma \in Fitt(\Delta)\} \leq G$ is finite. Since $Fitt(\Delta)$ is a normal subgroup of $\Delta$, $\mu$ is normalized by $\Gamma$. Hence, the centralizer of $\mu$ in $G$ contains a finite index subgroup of $\Gamma$. Since the centralizer of $\mu$ is a Zariski-closed subgroup of $G$ it contains $(H_\Gamma)^0 = H_\Gamma$. In particular, $\mu$ centralizes $\Gamma$. We consider now the homomorphism $\psi_u : Fitt(\Delta) \to U_Q$ which is given by $\gamma \mapsto \gamma_u$. The kernel of $\psi_u$ is contained in the finite group $\mu$. Since $Fitt(\Delta)$ is torsion-free, $\psi_u$ is injective. Assigning $\psi : \delta \gamma \mapsto \psi_u(\delta) \gamma$ defines an injective homomorphism $\psi : Fitt(\Delta) \Gamma \to (H_\Gamma)_Q$. (To see that $\psi$ is injective suppose that $1 = \psi(\delta \gamma)$, for $\delta \in Fitt(\Delta)$, $\gamma \in \Gamma$. Then $\gamma = \psi_u(\delta)^{-1}$ is unipotent, i.e., $\gamma \in u(\Gamma) \leq Fitt(\Gamma)$. Therefore $\delta \gamma \in Fitt(\Delta)$, and $\psi(\delta \gamma) = \psi_u(\delta \gamma)$, and hence $\delta \gamma = 1$. Clearly, the homomorphism $\psi$ is the identity on $\Gamma$. Let us put $\Gamma^* = \psi(Fitt(\Delta))$. Then $H_\Gamma$ is an algebraic hull for $\Gamma^*$. We consider now the extension $\Gamma^* \leq \Delta$. By Proposition A.3 there exist an algebraic group $I^*(H_\Gamma, \Delta)$ and an embedding $\psi^* : \Delta \to I^*(H_\Gamma, \Delta)_Q$ so that $\psi^*(\Delta) \cap I^*(H_\Gamma, \Delta) = \Gamma^*$. By construction, the group $I^*(H_\Gamma, \Delta)$ satisfies i) and iii) of Theorem A.7 with respect to $\psi^*$ and $\Delta$. Moreover, by our construction $\psi^*(Fitt(\Delta)) \leq U = u(I^*(H_\Gamma, \Delta))$.

We consider now the centralizer $Z_{I^*(H_\Gamma, \Delta)}(U)$ of $U$ in $I^*(H_\Gamma, \Delta)$. It is a $Q$-defined algebraic subgroup of the solvable by finite group $I^*(H_\Gamma, \Delta)$. Therefore $Z_{I^*(H_\Gamma, \Delta)}(U) = Z(U)S$, where $S$ is a $Q$-defined subgroup which consist of semisimple elements. We remark that $S = Z_{I^*(H, \Delta)}(U)_s$ is normal in $I^*(H, \Delta)$. Since $S \cap I^*(H, \Delta)$ centralizes $Fitt(\Gamma) \leq U$, the assumption that $\Delta$ has a strong Fitting subgroup implies that $S \cap I^*(\Delta) = \{1\}$. Let $\pi : I^*(H, \Delta) \to H_\Delta = I^*(H, \Delta)/S$ be the projection homomorphism. Since $H_\Delta$ is $Q$-defined with a strong unipotent radical, $H_\Delta$ with the embedding $\pi \psi^* : \Delta \to (H_\Delta)_Q$ is an algebraic hull for $\Delta$. \hfill \Box

**A.3 Properties of the algebraic hull**

Let $\Gamma$ be a virtually polycyclic group. We assume that $\Gamma$ admits an algebraic hull $H_\Gamma$. The next proposition implies Proposition A.2 and Corollary A.3.

**Proposition A.6** Let $k$ be a subfield of $\mathbb{C}$, and $G$ a $k$-defined linear algebraic group with a strong unipotent radical. Let $\rho : \Gamma \to G$ be a homomorphism so that $\rho(\Gamma)$ is Zariski-dense in $G$. Then $\rho$ extends uniquely to a morphism of algebraic groups $\rho_{H_\Gamma} : H_\Gamma \to G$. If $\rho(\Gamma) \subseteq G_k$ then $\rho_{H_\Gamma}$ is defined over $k$. 

20
Proof. We will use the diagonal argument. Therefore we consider the subgroup

\[ D = \{ (\gamma, \rho(\gamma)) \mid \gamma \in \Gamma \} \leq H \times G. \]

Let \( \pi_1, \pi_2 \) denote the projection morphisms onto the factors of the product \( H \times G \). Let \( D \) be the Zariski-closure of \( D \), and \( U = u(D) \) the unipotent radical of \( D \). The group \( D \) is a solvable by finite linear algebraic group, and \( D \) is defined over \( k \) if \( \rho(\Gamma) \leq G_k \). Let \( \alpha = \pi_1|_D : D \to H \). Since \( \Gamma \) is Zariski-dense in \( H \), \( \alpha \) is onto. In particular, \( \alpha \) maps \( U = D_u \) onto \( u(H) \). By [30 Lemma 4.36] we have \( \dim U \leq \dim \Gamma = \dim u(H) \), and hence \( \dim U = \dim u(H) \). In particular, it follows that the restriction \( \alpha : U \to u(H) \) is an isomorphism. Thus the kernel of \( \alpha \) consists only of semi-simple elements. Let \( x \in \ker \alpha \). Then \( x \) centralizes \( U \). Since \( \pi_2(U) = u(G) \), \( \pi_2(x) \) centralizes \( u(G) \). Since \( G \) has a strong unipotent radical, \( x \) is in the kernel of \( \pi_2 \), hence \( x = 1 \). It follows that the morphism \( \alpha \) is an isomorphism of groups. It is also an isomorphism of algebraic groups. If \( \rho(\Gamma) \leq G_k \), then \( \alpha \) is \( k \)-defined. One can also show that \( \alpha^{-1} \) is \( k \)-defined. (Compare e.g. [17 Lemma 2.3].) We put \( \rho_{H_\Gamma} = \pi_2 \circ \alpha^{-1} \) to get the required unique extension. \( \rho_{H_\Gamma} \) is \( k \)-defined if \( \rho(\Gamma) \leq G_k \). \hfill \Box

Remark. The proposition shows that the condition that \( \rho(\Gamma) \) has a strong unipotent radical forces the homomorphism \( \rho \) to be well behaved. For example, \( \rho \) must be unipotent on the Fitting subgroup of \( \Gamma \). See Proposition A.4 below.

We study some further properties of the algebraic hull. In particular, we characterize the abstract virtually polycyclic groups which admit an algebraic hull in the sense of Theorem A.1. Let us assume that \( \Gamma \) is a Zariski-dense subgroup of a linear algebraic group \( H \) with a strong unipotent radical.

Proposition A.7 We have \( \text{Fitt}(\Gamma) \leq u(H) \). In particular, \( u(\Gamma) = \text{Fitt}(\Gamma) \) and \( \text{Fitt}(\Gamma) \) is torsion-free.

Proof. Let \( F \) be the maximal nilpotent normal subgroup of \( H \). Clearly, \( F = F \) is a Zariski-closed subgroup. Therefore \( u(F) = u(H) \). Now since \( F \) is nilpotent, \( F_a \) is a subgroup, \( F_u = u(F) \) and \( F = F_a \cdot u(F) \) is a direct product of groups. Since \( H \) has a strong unipotent radical \( F_a \) must be trivial, and it follows that \( F = u(H) \). The Zariski-closure of \( \text{Fitt}(\Gamma) \) is a nilpotent normal subgroup of \( H \) and therefore \( \text{Fitt}(\Gamma) \) is contained in \( F \). Hence \( \text{Fitt}(\Gamma) \leq u(H) \). \hfill \Box

Let \( N = \text{Fitt}(\Gamma) \) be the Zariski-closure of \( \text{Fitt}(\Gamma) \) in \( H \). We just proved \( N \leq u(H) \).

Proposition A.8 Let \( X = Z_H(N) \) be the centralizer of \( N \) in \( H \). Let \( X^0 \) be its component of identity. Then \( X^0 \) is a nilpotent normal subgroup of \( H \), and \( X^0 \leq u(H) \). Moreover, \( Z_{\Gamma}(\text{Fitt}(\Gamma)) \leq \text{Fitt}(\Gamma) \).

Proof. Since \( X^0 \) is a connected solvable algebraic group, \( X^0 = U \cdot T \), where \( U \) is a connected unipotent group and \( T \) is a maximal torus in \( X^0 \). Let \( X_1 = [X^0, X^0] \) and define \( \Gamma_0 = \Gamma \cap H^0 \). Then \( \Gamma_0 \) is a polycyclic normal subgroup of \( \Gamma \), and \( \text{Fitt}(\Gamma_0) = \text{Fitt}(\Gamma) \). Since \( \Gamma_0 \leq H^0 \), it follows that \( [\Gamma_0, \Gamma_0] \leq u(\Gamma_0) \leq \text{Fitt}(\Gamma_0) \). This implies \( [X^0, X^0] \leq [H^0, H^0] = [\Gamma_0, \Gamma_0] \leq N \). We deduce \( [X^0, X_1] = [T, X_1] = 1 \). On the other hand, by [17 §10.6] all maximal tori in \( X^0 \) are conjugate by an element of \( X_1 \). Hence \( T \) must be an invariant subgroup of \( X^0 \). In particular, \( T \) is a normal abelian subgroup of \( H \). Therefore, by the proof of
the previous proposition, $T$ is contained in $u(H)$. Since $T$ consists of semisimple elements, $T = \{1\}$. Hence, $X^0 = Z(u(H))$.

Next put $X = Z_T(Fitt(\Gamma))$ and $X_0 = X \cap X^0$. Then $X_0$ is of finite index in $X$, nilpotent, and a normal subgroup of $\Gamma$. The latter implies that $X_0 \leq Fitt(\Gamma)$. It follows that $X_0$ is centralized by $X$. Since $X_0$ is of finite index in $X$ the commutator subgroup $[X,X]$ must be finite. Since $[X,X]$ is normal in $\Gamma$ it follows that $u(H_T)$ centralizes $[X,X]$. Since $H$ has a strong unipotent radical $[X,X] = \{1\}$. It follows that $X$ is an abelian normal subgroup of $\Gamma$, and hence $X \leq Fitt(\Gamma)$.

Recall that $\Gamma$ is said to have a strong Fitting subgroup if $Fitt(\Gamma)$ is torsion-free and contains its centralizer. We summarize:

**Corollary A.9** Let $\Gamma$ be virtually polycyclic. Then $\Gamma$ admits an algebraic hull $H$ if and only if $\Gamma$ has a strong Fitting subgroup.

We remark that this condition holds if and only if every finite normal subgroup of $\Gamma$ is trivial. In fact, let us assume that the maximal normal finite subgroup of $\Gamma$ is trivial. Then $Fitt(\Gamma)$ is torsion-free since its elements of finite order form a finite normal subgroup of $\Gamma$. Now put $X = Z_T(Fitt(\Gamma))$, and let $X_0$ be a polycyclic normal subgroup of finite index in $X$ which is nilpotent-by-abelian. From $[X_0,X_0] \leq Fitt(X) \leq Fitt(\Gamma)$ we deduce that $X_0 \leq Fitt(\Gamma)$. Therefore $[X,X]$ must be finite, and it follows from our assumption that $[X,X] = \{1\}$. Hence, $X \leq Fitt(\Gamma)$.
