We investigate the hierarchical structure of three-frequency resonances in nonlinear dynamical systems with three interacting frequencies. We hypothesize an ordering of these resonances based on a generalization of the Farey tree organization from two frequencies to three. In experiments and numerical simulations we demonstrate that our hypothesis describes the hierarchies of three-frequency resonances in representative dynamical systems. We conjecture that this organization may be universal across a large class of three-frequency systems.

PACS numbers: 05.45.-a

Nonlinear systems with two competing frequencies show resonances or lockings, in which the system locks into a resonant periodic response which has a rational frequency ratio \( \frac{p}{q} \). The locking increases with nonlinearity, from none in the linear regime, to a critical situation where the system is everywhere resonant. The subcritical system has quasiperiodic responses between different lockings, while at supercritical values of the nonlinearity, chaotic as well as periodic and quasiperiodic responses may occur. Resonances have been investigated theoretically and experimentally in many nonlinear systems, and their distribution in parameter space in the form of a devil’s staircase is now well understood, from the number theoretical concept of Farey trees \([2–7]\). However, all this applies to resonances generated by the interaction of two frequencies. Far less is known, by comparison, when there are three or more interacting frequencies.

Adding another frequency allows new phenomena to take place. Now as well as (two-frequency) resonance as before, there is a further possibility: three-frequency resonance, also known as weak resonance or partial mode locking. Three-frequency resonances are given by the nontrivial solutions of the equation \( af_0 + bf_1 + cf_2 = 0 \), where \( a, b, \) and \( c \) are integers, \( f_1 \) and \( f_2 \) are the forcing frequencies, and \( f_0 \) is the resonant response. They form a web in the parameter space of the frequencies \([8–11]\). In this paper, we hypothesize a local ordering of three-frequency resonances based on generalizing the Farey tree of two-frequency systems to three frequencies. We perform experiments and numerical simulations to show that our hypothesis is justified in representative dynamical systems with three interacting frequencies: a quasiperiodically forced circle map, a pair of parametrically coupled forced nonlinear oscillators, and an experimental system consisting of an electronic circuit of forced phase-locked loops. Our observations lead us to conjecture that the ordering we predict may be universal in a large class of dynamical systems with three interacting frequencies.

Firstly, we revise continued fractions and the Farey tree for everyration \( \frac{p}{q} \). The aim is to define a sequence of rational numbers that converges to \( \tilde{f} \). Strong convergence \([12]\) is defined for rational fractions \( \frac{p_i}{q_i} \), \( (p_i, q_i) \in \mathbb{Z} \) as

\[
\left\| \tilde{f} - \frac{p_i}{q_i} \right\| = |q_i \tilde{f} - p_i|.
\]

\( p_n/q_n \) is a best rational approximation if

\[
\left\| \tilde{f} - \frac{p_n}{q_n} \right\| < \left\| \tilde{f} - \frac{p_i}{q_i} \right\|
\]

for all \( (p_i, q_i) \) for any \( q_i \leq q_n \). Given \( \tilde{f} \), \( p_n \) and \( q_n \) are obtained by expanding \( \tilde{f} \) in continued fractions \( \tilde{f} = (a_1, a_2, a_3, \ldots) \), and truncating the expansion as \( p_n/q_n = (a_1, a_2, a_3, \ldots a_n) \) \([13]\). The \( p_n/q_n \) are then the strong convergents of \( \tilde{f} \). They give the sequence of fractions with lowest monotonically increasing denominators that converges to \( \tilde{f} \).

The physically motivated hypothesis invoked to explain the local ordering of the hierarchy of (two-frequency) resonances is that the larger the denominator, the smaller the plateau. The fraction with smallest denominator between \( p/q \) and \( r/s \), if they are sufficiently close that \( |qr - ps| = 1 \), when they are called adjacent, is \( (p+r)/(q+s) \). This fraction, known as the median, is then the most important resonance in the interval. Repeatedly performing the median operation

\[
\frac{p + r}{q + s} = \left\lfloor \frac{p}{q} + \frac{r}{s} \right\rfloor
\]
on a pair of adjacent rational numbers, we obtain a Farey tree. The Farey tree provides a qualitative local ordering of two-frequency resonances, and gives rise to a structure of plateaux at all rationals known as the devil’s staircase. The devil’s staircase in turn is the skeleton for the layout of the resonances in parameter space as Arnold tongues \([3–4]\).

Now consider the case of three frequencies, one internal \( f_0 \), and two external \( f_1 \) and \( f_2 \). We may divide through by the autonomous frequency \( f_0 \), to give \( f_1' = f_1/f_0 \), and \( f_2' = f_2/f_0 \). We aim to come up with two convergent sequences of rational numbers with the same denominator, \( p_n/k_n \) and \( q_n/k_n \), which are strong convergents to \( f_1' \) and \( f_2' \) respectively. As before, strong convergence is defined as

\[
\left\| (f_1', f_2') - \left( \frac{p_i}{k_i}, \frac{q_i}{k_i} \right) \right\| = |k_i(f_1', f_2') - (p_i, q_i)|.
\]

Thus \( (p_n/k_n, q_n/k_n) \) are best rational approximants if
\[ \left\| (f_1^*, f_2^*) - \left( \frac{p_n}{k_n}, \frac{q_n}{k_n} \right) \right\| < \left\| (f_1^t, f_2^t) - \left( \frac{p_i}{k_i}, \frac{q_i}{k_i} \right) \right\| \]  

(5)

for all triplets of integers \((p_i, q_i, k_i)\) for any \(k_i \leq k_n\). So we may write

\[ \varepsilon_1 = \left\| \frac{p_n}{k_n} - f_1^t \right\| = |k_n f_1^t - p_n|, \]

(6)

\[ \varepsilon_2 = \left\| \frac{q_n}{k_n} - f_2^t \right\| = |k_n f_2^t - q_n|, \]

(7)

where we wish to obtain the integers \(p_n, q_n\) and \(k_n\). This general problem has not been solved \([14,15]\), however, we may set \(\varepsilon_1 = \varepsilon_2\), so that both approximations should be equally good or bad. If we do this, we can equate \(|k_n f_1^t - p_n| = |k_n f_2^t - q_n|\), and ask what is \(k_n\). There are two solutions \(k_n = (q_n \pm p_n)/(f_2^t \pm f_1^t)\). At this point we must remember that \(k_n\) is an integer, so these solutions require that the frequencies be rescaled by \(f_2^t \pm f_1^t\). For which we define for the first solution \(f_1 = f_1^t/(f_1^t + f_2^t)\), \(f_2 = f_2^t/(f_1^t + f_2^t)\), and similarly for the other solution \(f_1^t = f_1^t/(f_2^t - f_1^t)\), \(f_2^t = f_2^t/(f_2^t - f_1^t)\). The two solutions give rise to different \(\varepsilon^*\)’s

\[ \varepsilon = |(p_n + q_n) f_1 - p_n| = |(p_n + q_n) f_2^t - q_n|, \]

(8)

\[ \varepsilon^* = |(q_n - p_n) f_1^t - p_n| = |(q_n - p_n) f_2 - q_n|, \]

(9)

from which one can obtain \(\varepsilon/\varepsilon^* = |(f_2 - f_1)/(f_1 + f_2)| < 1\). So in this sense the \((f_1, f_2)\) solution is better than the \((f_1^*, f_2^*)\) solution.

Now sticking with the \((f_1, f_2)\) solution, \(p_n, (p_n + q_n),\) and \(q_n\) are obtained from the continued fraction expansions of \(f_1\) and \(f_2\). Since

\[ f_1 = \frac{f_1^t}{f_1^t + f_2^t} = \frac{f_1 + f_2}{f_1 + f_2} = 1 + \frac{1}{\frac{f_1}{f_2}}, \]

(10)

\[ f_2 = \frac{f_2^t}{f_1^t + f_2^t} = \frac{f_2 + f_1}{f_1 + f_2} = 1 + \frac{1}{\frac{f_2}{f_1}}, \]

(11)

if we have the continued fraction expansion of \(f_1/f_2 = (a_1, a_2, a_3, \ldots)\), that of \(f_1 = (a_1 + 1, a_2, a_3, \ldots)\), and \(f_2 = (1, a_1, a_2, a_3, \ldots)\) Hence if \(p_n/q_n\) is the \(n\)th strong convergent of \(f_1/f_2\), or equivalently of \(f_1\), given by this continued fraction expansion, \(p_n/(p_n + q_n)\) and \(q_n/(p_n + q_n)\) are the strong convergents of \(f_1\) and \(f_2\) respectively. If \(p_n/q_n\) is a such a convergent of \(f_1/f_2\), we may define as generalized adjacents any pair of \((f_i/r_i, f_j/r_j)\), with \(f \in \mathbb{R}\) and \(r \in \mathbb{Z}\), that satisfy

\[ |f r_j - f_j r_i| = \left| f_1 q_n - f_2 p_n \right|. \]

(12)

From this definition, the subharmonics \(f_1/p_n\) and \(f_2/q_n\) are generalized adjacents, and the median between them is

\[ f_* = \frac{f_1 + f_2}{p_n + q_n}, \]

(13)

which by extension from the two-frequency case we hypothesize to be the largest plateau between \(f_1/p_n\) and \(f_2/q_n\). Starting with \((f_1^*, f_2^*)\) instead of \((f_1, f_2)\), we obtain the generalized median \(f_*^* = (f_2 - f_1)/(q_n - p_n)\); both \(f_*\) and \(f_*^*\) are shown in Fig. 1(a). The generalized median operation

\[ \frac{f_1}{r_1} \pm \frac{f_2}{r_2} = \frac{f_1 + f_2}{r_1 + r_2} \]

(14)

then provides us with a generalized Farey tree for three frequencies; in Fig. 1(b) we show the first three levels of the tree obtained by recursive application of Eq. (14) to the adjacents \(f_1/p_n\) and \(f_*^*\).

FIG. 1. (a) Schematic diagram of the frequency line, showing the relative position of \(f_*\) and \(f_*^*\) and their respective \(p_n, q_n\) harmonics that approximate \(f_1\) and \(f_2\) at equal distance. (b) Generalized Farey tree starting from the adjacents \(f_1/p_n\) and \(f_*^*\). The first mediant is \(f_2/q_n\); at the second level we obtain \(f_*\) and \((2f_2 - f_1)/(2q_n - p_n)\), and so on.

Let us take as an example a three-frequency system with the two external frequencies set to \(f_1 = 2100\) Hz and \(f_2 = 3600\) Hz. The frequency ratio \(f_1/f_2\) is then 7/12. The continued fraction expansion for \(f_1/f_2\) is \((1, 1, 2, 1, 1)\), and the different truncations of this produce the convergents of 7/12, which are \(1/1, 1/2, 3/5, \) and \(4/7\). So we take \(4/7\) as an approximation to the higher-order rational 7/12, or equivalently in terms of the original frequencies, \(f_1/f_2 \approx 2000\) Hz/3500 Hz approximates \(f_1/f_2 \approx 2100\) Hz/3600 Hz with a detuning of 100 Hz. Between the adjacents \(f_1/4 = 525\) Hz and \(f_2/7 = 514.3\) Hz lies the mediant \(f_* = (f_1 + f_2)/11 = 518.2\) Hz, which we have hypothesized to be the widest resonance in this interval, and recursively applying the mediant operation gives us the Farey tree that predicts the entire hierarchy of resonances in the interval. We now proceed to test this hypothesis in three-frequency dynamical systems.
of the two oscillators are synchronized 1/1. We filter the ou-
circuits made up of voltage-controlled oscillators (VCOs) are
ator shown in Fig. 2(a) [16]. Two phase-locked loop (PLL)
frequencies of both oscillators. If the two values coincidewe
ponents at the external frequencies and we measure the output
puts of the two oscillators in order to attenuate the compo-
with two independent periodic forces. Typically, the outputs
forced with two independent external forces. (c) The generalized Fareytree
value of the
th external force is equivalent to a linear change
in the natural frequency of the ith oscillator). The results are
presented in Fig. 2(b) for the interval \( f_2/7, f_1/4 \) for \( f_1 \) and
\( f_2 \) fixed at 2100 Hz and 3600 Hz respectively. This appears to
be a typical devil’s staircase familiar from periodically driven
oscillators. It is, however, a three-frequency devil’s staircase:
the plateaux correspond to solutions with three linearly de-
pendent basic frequencies (the frequency plotted plus the two
forcing frequencies) instead of to periodic solutions. As pre-
dicted, the generalized median \( f_s \) = 518.2 Hz is the largest
resonance in the interval, moreover, the generalized Farey tree
shown in Fig. 2(c) gives the entire hierarchy of resonances of
Fig. 2(b).

We have constructed the three-frequency electronic oscil-
ator shown in Fig. 2(a) [16]. Two phase-locked loop (PLL)
circuits made up of voltage-controlled oscillators (VCOs) are
coupled through a lowpass and integrator network and forced
with two independent periodic forces. Typically, the outputs
of the two oscillators are synchronized 1/1. We filter the out-
puts of the two oscillators in order to attenuate the compo-
nents at the external frequencies and we measure the output
frequencies of both oscillators. If the two values coincide we
plot them against the DC offset of oscillator 1, which is used
as the control parameter (for the circuit a variation in the mean
value of the \( \omega_i \) external force is equivalent to a linear change
in the natural frequency of the \( \omega_i \) oscillator). The results are
presented in Fig. 2(b) for the interval \( f_2/7, f_1/4 \) for \( f_1 \) and
\( f_2 \) fixed at 2100 Hz and 3600 Hz respectively. This appears to
be a typical devil’s staircase familiar from periodically driven
oscillators. It is, however, a three-frequency devil’s staircase:
the plateaux correspond to solutions with three linearly de-
pendent basic frequencies (the frequency plotted plus the two
forcing frequencies) instead of to periodic solutions. As pre-
dicted, the generalized median \( f_s \) = 518.2 Hz is the largest
resonance in the interval, moreover, the generalized Farey tree
shown in Fig. 2(c) gives the entire hierarchy of resonances of
Fig. 2(b).

We have integrated an exactly soluble system of ordinary
differential equations of Eq. (15). The system parameters
are equivalent to those of Fig. 2(b).

We have integrated an exactly soluble system of ordinary
differential equations with three interacting frequencies [24]

\[
\ddot{x}_i + (4b\dot{x}_i^2 - 2a)x_i + b^2\dot{x}_i^5 - 2abx_i^3 + (\omega_0(t)^2 + a^2)x_i = f_i(t)
\]

(15)

for \( i = 1, 2 \). The external forces and the coupling term
are chosen in such a way as to preserve the piecewise in-
tegrability of the overall system. The oscillators are cou-
pled parametrically, their intrinsic frequency changing every
the coordinate of one of them changes sign
\( \omega_0(t) = \omega_{0i} + \text{sgn} u_i(t) \text{sgn} u_{1i}(t) \Delta_i \).

The ith oscillator is driven by an impulsive external force
\( f_i(t) = V_{Ei} \sum_{k} \delta(t - n\tau_{Ei}) \) of
frequency \( \omega_i \), whose effect is to produce a discontinuity
\( V_{Ei} \) in the oscillator velocity at times \( n\tau_{Ei} = n/(2\pi\omega_i) \).

We have performed a power spectrum analysis of the output of both os-
cillators while varying the intrinsic frequency of oscillator 1.

We display in Fig. 3 the most prominent peak in each spec-
trum against \( \omega_{0i} \) for a parameter region equivalent to that of
Fig. 2(b), and in which the two oscillators are also synchron-
ized 1/1. All detectable resonances are again well described
by the Farey tree structure of Fig. 2(c).

Our final example of a three-frequency system is the
quasiperiodically forced circle map

FIG. 2. (a) The electronic circuit in block-diagram form. Two
coupled voltage-controlled oscillators (VCOs) are forced with two
independent external forces. (b) Three-frequency devil’s staircase
for the circuit. The straight lines correspond to intervals of the DC
offset within which the fundamental frequency of the output remains
constant. We varied the DC offset of input 1 in steps of 1 mV in the
interval 0.90 V to 1.05 V, which corresponds to frequency responses
of the circuit between 514.28 Hz and 525.00 Hz. Only intervals with
a stability width greater than 2 mV are plotted. The external frequen-
cies are fixed at 2100 Hz and 3600 Hz. (c) The generalized Farey tree
predicts the organization of all the frequency values observed in (b).

FIG. 3. The three-frequency devil’s staircase for the system of
ordinary differential equations of Eq. (15). The system parameters
are equivalent to those of Fig. 2(b).
\[ \phi' = \phi + \Omega_n + \frac{k}{2\pi} \sin 2\pi \phi \mod 1. \quad (16) \]

The quasiperiodic sequence \( \Omega_n \) is the time interval between successive pulses of a sequence composed of the superposition of two periodic subsequences, one of period equal to one and the other of period \( T_1/T_2 < 1 \) (with no loss of generality), multiplied by the value of the intrinsic frequency of the oscillator. In Fig. 4(a) we demonstrate that, for the same input frequencies as in the previous two cases, the output in the form of a devil’s staircase is qualitatively unchanged; once again its organization is given by the generalized Farey tree. Moreover, Fig. 4(b) shows how three-frequency resonances are arranged globally in the form of devil’s ramps in the parameter space.

By generalizing the known Farey tree structure of two-frequency resonances for three frequencies we have predicted the organization of three-frequency resonances in dynamical systems with three interacting frequencies. Our results for three different three-frequency dynamical systems for the same ratio of forcing frequencies \( f_1/f_2 \) show that in each example the predicted generalized Farey tree hierarchy is observed. We have repeated these experiments and simulations for different frequency ratios, both rational, as the example presented here, and irrational, for example \( f_1/f_2 = (1 + \sqrt{5})/2 \), the golden ratio. In every case we have examined, the local ordering of resonances around the convergents in the devil’s staircase — slices through the devil’s ramps of Fig. 4(b) — is well described by the generalized Farey tree hierarchy. We conclude that the organization we have described here is widespread, and conjecture that it may be universal in a large class of three-frequency systems.
