INTRODUCTION

In the nationwide survey on the helminthic infection in the Republic of Korea (Korea), the prevalence of clonorchiasis, Clonorchis sinensis infection, was 1.86%, 932,540 residents with this endemic disease estimated. Nowadays, it is the highest value among the prevalences of parasitic diseases in Korea [1]. The prevalence of this endemic disease has maintained at relatively high levels in residents of riverside areas in Korea [2-6]. Especially, Cho et al. [5] reported the egg positive rates of Cl. sinensis in residents living in the 4 river basins, Nakdong-gang (gang means River), Seomjin-gang, Yeongsan-gang and Geum-gang, located in southern part of Korea. Recently, Jeong et al. [6] reported the prevalences of clonorchiasis in the adjacent residents of 5 major rivers, i.e., Nakdong-gang, Seomjin-gang, Geum-gang, Yeongsan-gang and Han-gang. However, the endemicity of this trematode infections is rarely reported in the riverside residents of Tamjin-gang except for the Seo et al. [2] performed in 1981.

Many Korean parasitologists examined freshwater fishes, the infection source of clonorchiasis, from various endemic areas to estimate the endemicities of liver fluke infections [7-16]. Especially, in 2008, Kim et al. [10] widely surveyed freshwater fishes from 34 localities to know the infection status with Clonorchis sinensis metacercariae (CsMc) in Korea. Cho et al. [12] investigated the infection status of CsMc in freshwater fish from Gangwon-do (do = Province), Korea.

Infection Status with Clonorchis sinensis Metacercariae in Fish from Tamjin-gang (River) in Jeollanam-do, Republic of Korea

Abstract: The present study was performed to investigate the infection status with Clonorchis sinensis metacercariae (CsMc) in fishes from 2 sites, the middle and lower reaches, of Tamjin-gang (River) in Jeollanam-do, the Republic of Korea. Total 1,132 fishes in 22 species were collected from the middle reaches in Jangheung-gun for 4 years (2014-2017) and 517 fishes in 17 species were also collected from the lower reaches in Gangjin-gun in 2014 and 2017. They were all individually examined with the artificial digestion method in our laboratory. CsMc were detected in 322 (28.5%) out of 1,132 fishes from Jangheung-gun, and in 161 (31.1%) out of 517 fishes from Gangjin-gun, and their densities were 51 and 57 per fish infected each. In the fish species with CsMc, positive rates were 61.5% in Jangheung-gun and 62.7% in Gangjin-gun. A total of 222 Pungtungia herzi were examined and they were all infected with CsMc. The average intensity was 103 CsMc in the index fish, P. herzi (95 in Jangheung-gun and 121 in Gangjin-gun). In P. herzi bimonthly examined in 2017, the intensity was commonly most higher in March in 2 surveyed sites, however the significant seasonal endemicity was not showed. Conclusively, it was confirmed that CsMc is more or less prevalent in fishes from Tamjin-gang and their endemicity is higher in fish from the lower reaches in Gangjin-gun than the middle reaches in Jangheung-gun in Jeollanam-do, Korea.

Key words: Clonorchis sinensis, metacercaria, freshwater fish, index fish, Pungtungia herzi, Tamjin-gang

INTRODUCTION

In the nationwide survey on the helminthic infection in the Republic of Korea (Korea), the prevalence of clonorchiasis, Clonorchis sinensis infection, was 1.86%, 932,540 residents with this endemic disease estimated. Nowadays, it is the highest value among the prevalences of parasitic diseases in Korea [1]. The prevalence of this endemic disease has maintained at relatively high levels in residents of riverside areas in Korea [2-6]. Especially, Cho et al. [5] reported the egg positive rates of C. sinensis in residents living in the 4 river basins, Nakdong-gang (gang means River), Seomjin-gang, Yeongsan-gang and Geum-gang, located in southern part of Korea. Recently, Jeong et al. [6] reported the prevalences of clonorchiasis in the adjacent residents of 5 major rivers, i.e., Nakdong-gang, Seomjin-gang, Geum-gang, Yeongsan-gang and Han-gang. However, the endemicity of this trematode infections is rarely reported in the riverside residents of Tamjin-gang except for the Seo et al. [2] performed in 1981.

Many Korean parasitologists examined freshwater fishes, the infection source of clonorchiasis, from various endemic areas to estimate the endemicities of liver fluke infections [7-16]. Especially, in 2008, Kim et al. [10] widely surveyed freshwater fishes from 34 localities to know the infection status with Clonorchis sinensis metacercariae (CsMc) in Korea. Cho et al. [12] investigated the infection status of CsMc in freshwater fish from 3 wide regions, which tentatively divided by the latitudinal levels of Korean peninsula in 2011. Cho et al. [13] also surveyed on the prevalence of zoontic trematode metacercariae in freshwater fish from Gangwon-do (do = Province), Korea.
Sohn et al. [14] investigated the infection status of digenetic trematode metacercariae including C. sinensis in freshwater fish from the water systems of Hantan-gang and Imjin-gang located in relatively northern regions of Korea. Recently, Sohn et al. [15] surveyed the prevalence of CsMc in freshwater fishes from the water systems of Seomjin-gang. Sohn et al. [16] also reported the infection tendency of CsMc by the subfamily groups in Cyprinidae fish hosts from a highly endemic site, Wicheon (a branch of Nakdong-gang), in Gunwi-gun, Gyeongsangbuk-do, Korea.

Tamjin-gang is one of the 3 major rivers in Jeollanam-do together with Seomjin-gang and Yeongsan-gang. It rises from a mountinous area between Yuchi-myeon (myeon = township) in Jangheung-gun (gun = county) and Geumjeong-myeon in Yeongam-gun, flows via Jangheung-gun and Gangjin-gun and flows into the South Sea in the Gangjin Bay, Jeollanam-do, Korea [17]. Its riverside areas have been known as the endemic area of intestinal fluke, Metagonimus yokogawai and heterophyid flukes [2,18-22]. However, the infection status with CsMc in fish from this river has not been widely and systematically examined yet. Therefore, we performed the present study to investigate the infection status with CsMc in fish from 2 local sites of Tamjin-gang in Korea.

**MATERIALS AND METHODS**

**Fish collection**

Total 1,132 fishes in 22 species were collected in the middle reaches of Tamjin-gang (River) in Jangheung-gun (Latitude: 34.4257; Longitude: 126.5432), Jeollanam-do, Korea for 4 years (2014-2017). Total 517 fishes in 17 species were also collected in the lower reaches of Tamjin-gang in Gangjin-gun (Latitude: 34.3805; Longitude: 126.4851), Jeollanam-do in 2104 and 2017.

Fish species (no. of fish) examined were Carassius auratus (30), Zacco platypus (20), Acheilognathus yamatsutae (11), Odontobutis platycephala (6), Micropterus salmoides (5), Acanthorhodeus gracilis (1) including 6 ones with CsMc in Table 1. Total 243 fishes in 15 species were examined in 2015. Fish species (no. of fish) examined were Z. temminckii (32), C. auratus (30), Z. platypus (27), Coreoperca kawamebati (27), Plectognous altivelis (18), Acheilognathus koreensis (4) including 9 ones with CsMc in Table 1.

Total 302 fishes in 16 species were examined in 2016. Fish species (no. of fish) examined were Z. temminckii (28), C. kawamebati (24), P. altivelis (22), C. auratus (20), O. platycephala (12), Siniperca scherzeri (6), C. herzi (3) and M. salmoides (3) including 8 ones with CsMc in Table 1. Total 420 fishes in 18 species were examined in 2017. Fish species (no. of fish) examined were Z. temminckii (62), Z. platypus (61), C. auratus (41),

Table 1. Infection status of Clonorchis sinensis metacercariae in fishes from the middle reaches of Tamjin-gang (River) in Jangheung-gun, Jeollanam-do

| Year and fish sp. | No. of fish examined | No. (%) of fish infected | No. of CsMc detected |
|-------------------|-----------------------|--------------------------|----------------------|
| 2014              |                       |                          |                      |
| Pseudogobio esocinus | 25                    | 2 (8.0)                  | 1-2                  | 1.5 |
| Hemibarbus longirostris | 20                  | 19 (95.0)                | 1-20                 | 6.8 |

| Subtotal           | 166                   | 129 (77.7)               | 1-240                | 28.3 |
| Total              | 524                   | 322 (61.5)               | 1-950                | 50.9 |
C. kawamebari (33), O. platycephala (18), P. altivelis (12), P. esocinus (12), C. herzi (10), A. yamatsutae (3) and Cyprinus carpio (2), including 8 ones with CsMc in Table 1.

Fishes collected from the lower reaches of Tamjin-gang in Gangjin-gun

Total 110 fish in 12 species were examined in 2014. Fish species (no. of fish) examined were Z. platypus (20), C. auratus (19), Z. temminckii (5), Lateolabrax japonicus (2), O. platycephala (1) and Mugil cephalus (1) including 6 ones with CsMc in Table 3. Total 407 fishes in 14 species were examined in 2017. Fish species (no. of fish) examined were Z. platypus (55), C. auratus (43), P. altivelis (40), C. kawamebari (25), O. platycephala (25), Z. temminckii (21) and C. herzi (3), including 7 ones with CsMc in Table 3.

Examination methods

All collected fishes with ice were transferred to the laboratory of the Department of Parasitology and Tropical Medicine, Gyeongsang National University College of Medicine, Jinju, Korea. After the identification of fish species, they were individually ground with a mortar or grinder. Each ground fish meat was mixed with artificial gastric juice and the mixture was incubated at 36°C for 2 hr. The digested material was filtered with 1 × 1 mm of mesh, and washed with 0.85% saline until the supernatant is clear. The sediment was carefully examined under a stereomicroscope. CsMc were separately collected by the general feature [11], and they were counted to get hold of infection rates (%) and densities (No. of CsMc per fish infected) by fish species.

**RESULTS**

Infection status of fish with CsMc in middle reaches of Tamjin-gang

The metacercariae of *C. sinensis* (CsMc) were detected in 322 (61.5%) out of 524 fishes in 16 species from the middle reaches of Tamjin-gang in Jangheung-gun, Jeollanam-do, and their average density was 51 per fish infected. In the positive fish species with CsMc, prevalences were 59.4%, 61.0%, 47.8%, and 77.7% from 2014 to 2017 and their densities were 69, 42, 82 and 28 per fish infected respectively. The infection status with CsMc by the fish species and surveyed years was detailedly shown in Table 1. All 152 striped shinner, *P. herzi*, examined were infected with CsMc, of which intensities were 186, 66, 181, and 45 in average from 2014 to 2017. In case of this fish species examined in 2017, intensities with CsMc were 186, 66, 82 and 28 per fish infected respectively. The infection status with CsMc in lower reaches of Tamjin-gang

The CsMc were detected in 161 (62.7%) out of 257 fishes in 8 species from the lower reaches of Tamjin-gang in Gangaingun, Jeollanam-do, and their average density was 57 per fish infected. In the positive fish species, prevalences were 33.9%
in 2014 and 71.8% in 2017 and their densities were 39 and 60 CsMc per fish infected. The infection status with CsMc by the fish species and surveyed years was detailedly revealed in Table 3. All 70 striped shinner, *P. herzi*, examined were infected with CsMc, of which intensities were 242 and 115 in average in 2014 and 2017. In case of this fish species examined in 2017, intensities with CsMc were 195 in March, 64 in May, 59 in July and 136 in October respectively (Table 4).

Comparison of the infection status of fish with CsMc in 2 surveyed sites of Tamjin-gang

Total 1,649 fishes were examined in this study. Among them, 1,132 (68.7%) were caught from the middle reaches of Tamjin-gang in Jangheung-gun and remain 517 (31.4%) were from the lower reaches in Gangjin-gun, Jeollanam-do. The overall positive rate with CsMc was 29.3% in 1,649 fishes from Tamjin-gang. That was 28.5% in 1,132 fishes from Jangheung-gun and was 31.1% in 517 fishes from Gangjin-gun. A total of 222 *P. herzi* were examined and they were all infected with CsMc. The average density was 103 CsMc in the index fish, *P. herzi* (95 in Jangheung-gun and 121 in Gangjin-gun) (Table 5).

**DISCUSSION**

By the present study, it was confirmed that CsMc are more or less prevalent in fish from Tamjin-gang. Total positive rate, 29.3%, and average metacercarial density, 53 per fish infected, were not so high (Table 5). However, the prevalence (100%) and metacercarial density (103) in the index fish, *P. herzi*, were shown the relatively higher level. In the positive fish species group, the endemcity of CsMc was slightly higher in fish from the lower reaches in Gangjin-gun (62.7%; density: 57) than in fish from the middle reaches in Jangheung-gun (61.5%; 51). In *P. herzi*, the metacercarial density was higher in the lower reaches (121) than in the middle reaches (95). These findings suggested that the endemcity with CsMc is more or less higher in fish from the lower reaches in Gangjin-gun than in fish from the middle reaches in Jangheung-gun, Jeollanam-do, Korea.

Cho et al. [12] examined fishes from 2 sites, Gangjin-gun (58 fish in 11 spp.) and Jangheung-gun (52 fish in 9 spp.), of Tamjin-gang in 2005. They detected 206 CsMc per infected fish in 39 (76.5%) out of 51 fishes (9 spp.) from Gangjin-gun, but they found no CsMc in 52 fishes from Jangheung-gun. From these findings, we can speculate that the endemcity of CsMc has been highly maintained in fish from Gangjin-gun, however, no CsMc in fish from Jangheung-gun unlike in this study is questionable. Two fish species, *P. herzi* and *S. variegatus wakiye*, were showed to be the highly susceptible fish hosts of *C. sinensis* in Cho et al. [12]. Their susceptibility index of CsMc, 420 in *P. herzi* and 356 in *S. variegatus wakiye*, were very high, when we compared with those of present study, 103 in *P. herzi*. On the other hand, Sohn et al. [16] reported that the susceptibility index of CsMc is 1,310 in 323 gobioninid fishes, i.e., 169 *P. herzi*, 117 *Squalidus* spp., 25 *S. variegatus wakiye*, and 12 *Pseudorasbora parva*, from Wicheon in Gunwi-gun, Gyeongsangbuk-do. Kim et al. [10] reported 81 CsMc in average densi-

| No. of fish examined | 1,332 (68.7) | 517 (31.4) | 1,649 (100) |
| Overall positive rate (%) | 322/1,132 (28.5) | 161/517 (31.1) | 483/1,649 (29.3) |
| Total metacercarial density | 50.9 | 57.2 | 53.0 |
| No. (%) of *P. herzi* examined | 152 (13.4) | 70 (13.5) | 222 (13.5) |
| Metacercarial density in *P. herzi* | 95 | 120.9 | 103.2 |

*Positive rate: No. of fish infected/No. of fish examined ×100; metacercarial density: mean no. of CsMc per fish infected.

*No. of *P. herzi*/Total No. of fish examined ×100.
ty in 10 *P. herzi*, from Yangcheon in Sancheong-gun, Gyeongsangnam-do.

In the metacercarial surveys for the epidemiology of zoonotic trematode infections, the sampling of fish is one of the important factors to obtain the more precise information. Total 1,649 fishes were collected from 2 sites (1,132 from the middle reaches in Jangheung-gun and 517 from the lower reaches in Gangjin-gun, Jeollanam-do) of Tamjin-gang in this study. In the middle reaches, total 1,132 fishes in 22 species were examined for 4 years (2014-2017) and a total of 517 fishes in 17 species from the lower reaches were examined in 2014 and 2017. The difference of fish number examined in 2 surveyed areas is depends upon the number of examined years. The striped shinner, *P. herzi* (222: 13.5%), was the most dominant fish species, and followed by pale chub, *Z. platypus* (213: 12.9%), dark chub, *Z. tenminchii* (178: 10.8%), crucian carp, *C. auratus* (178: 10.8%), and goby minnow, *P. esocinus* (137: 8.3%) among the fish species examined in this study. The numbers of striped shinner examined in each 2 reaches were 152 (middle: 13.4%) and 70 (lower: 13.5%). Those of pale chub were 138 (12.2%) and 75 (14.5%), and of crucian carp were 116 (10.3%) and 62 (12.0%). According to the above findings, major 4 fish species were collected in similar proportions in 2 surveyed areas. However, the dark chub, *Z. tenminchii*, was collected more in the middle (152: 13.4%) than in the lower reaches (26: 5.0%).

Total 51 fish species (in 36 genera 9 families) have been reported as the second intermediate hosts of *C. sinensis* in Korea [7-16]. In the present study, CsMc were detected in 16 fish species, i.e., *Acanthorhodeus gracilis*, *A. macropterus*, *Acheilognathus lanceolatus*, *A. koreensis*, *A. rhombetus*, *A. yamatsutae*, *Coreoperca herzi*, *Hemibarbus longirostris*, *Hemiculter ilishaeformis*, *Odontobutis platycephala*, *Pseudogobio esocinus*, *Pungtungia herzi*, *Sarcocheilichthys nigripinnis morii*, *S. variegatus watkiye*, *Squalidus gracilis majimae*, and *Zacco platypus*. They all had been listed as the second intermediate hosts of *C. sinensis* and *Zacco platypus* [9]. In the present study, CsMc were detected in 16 fish species examined in this study, 5 ones, i.e., crucian carp (*C. auratus*), Korean and Japanese aucha perch (*C. herzi* and *C. kawamebari*), sweet smelt (*Plecoglossus altivelis*), and Korean dark sleeper (*O. platycephala*), are frequently eaten in raw in Korea. A total of 472 (28.6%) fish edible in raw, i.e., 178 crucian carp, 19 Korean and 109 Japanese aucha perch, 92 sweet smelt and 74 Korean dark sleeper, were examined in this study, but only 2 (0.4%) fish, 1 *C. herzi* and 1 *O. platycephala*, were infected with only 1 CsMc of each. In even such a highly endemic area, Wicheon, total 3 (8.8%) out of 34 *C. auratus* were infected with total 3 CsMc, 2 (11.1%) *C. herzi* were retained with 4 CsMc and only 1 (33.3%) *S. scherzeri* were infected with total 6 CsMc, respectively [16]. No CsMc were detected in 4 fish species, i.e., *C. herzi* (57), *C. auratus* (42), *S. scherzeri* (11), and *C. carpio* (2), from Seomjin-gang [15]. Fortunately, these fish species edible in raw are less prevalent with CsMc in Korea. Then, what kinds of factors are acted in maintenance of the endemicity of clonorchiasis in Korea? The chopping board contaminated with fish meat may be act as the other transmission route of clonorchiasis in the riverside endemic areas of Korea.

Conclusively, it is confirmed that the endemicity of CsMc is moderately high in fishes from Tamjin-gang, which is known to be the endemic area of heterophyid flukes, including *Metastrongylus yokogawai* and *Heterophyes nocens* [2,18-22]. The surveillances on the zoonotic fish-borne trematode infections should be constantly done in this river basin.

**ACKNOWLEDGMENTS**

This study was supported by an anti-communicable diseases control program, 2014E5400200 (Investigation of fish-borne parasites and acquisition of their biological resources in the southern regions of Korea) of National Institute of Health (NIH), Korea Centers for Disease Control and Prevention (KCDCP). We thank Jung-A Kim and Hee-Joo Kim (Department of Parasitology and Tropical Medicine, Gyeongsang National University College of Medicine, Jinju, Korea), for their...
help in the examination of fish.

CONFLICT OF INTEREST
