A Research on Determination of Some Properties of Butter Made from Creams Extracted from Whey and Milk

Asya Çetinkaya

ABSTRACT

In this study, it was aimed to determine the effect of some production parameters on the characteristics of butters made from whey, which is an important dairy by-product, and creams obtained from milk.

The acidity values of milk, whey, cream, and butter were respectively detected as 0.17±0.00%, 0.13±0.01%, 0.22±0.01%, 0.24±0.01%, 0.26±0.00%, 0.25±0.01%, fat values were respectively detected as; 3.50±0.14%, 0.60±0.19%, 39.0±0.34%, 43.0±0.35%, 80.0±0.46%, 84.0±0.42% and protein values were respectively detected as; 3.30±0.19%, 0.68±0.03%, 0.93±0.12%, 0.54±0.03%, 0.51±0.02%, 0.58±0.00%. 10 saturated and 7 unsaturated fatty acids were detected in cream and whey butter samples. It was seen that the most common fatty acids were palmitic, stearic, myristic and oleic acid, and the amount of oleic, stearic and linoleic acid was higher in whey butter.

In conclusion, we can state that whey, which is an important dairy residue, can be used as an alternative raw material in butter production.

Keywords: butter, chemical properties, fatty acid components, whey.

I. INTRODUCTION

Milk fat is a component that plays a role in the physical characteristics, taste, aroma and nutritional value of dairy products. In addition to being a good source of energy in terms of nutritional physiology, it is also of great importance because it has its medium chain fatty acids, essential unsaturated fatty acids such as linoleic and arachidonic acid, fat-soluble vitamins A, D, E, K, and especially conjugated linoleic acid (CLA) in its composition [1].

The fatty acid composition of milk not only has an effect on the physical characteristics, oxidative stability and organoleptic quality of dairy products, but it also has positive effects on human health [2]. Butter is a dairy product that is physically obtained from milk, cream, yogurt, or by-products (whey, buttermilk, etc.) and does not contain any fat other than milk fat [3]. Butter is a dairy product that contains milk fat, which is the most important component of milk, and is an important dairy product in terms of its economic as well as nutritional value [4].

In addition, according to the Communiqué No. 2005/19 of the Turkish Food Codex, butter is a dairy product that should have a minimum of 80% and a maximum of 90% milk fat, a maximum of 2% non-fat milk dry matter and a maximum of 16% water content in its total weight [5].

In the composition of butter, in addition to low and high molecular fatty acids, monoenic and polyenic unsaturated fatty acids, butyric, caprylic and caprylic acids from 4-6-8 carbon saturated fatty acids and unsaturated acids, palmitolein, oleic and linoleic acids are in liquid state at room temperature and other fatty acids are in solid state. The unique fatty acid composition and low melting point of milk fat, which constitutes the structure of butter, plays a role in easier digestion of milk fat [6]. Since it is in the liquid state when secreted and available for digestion, butter is easier to digest and has a higher physiological value compared to other fats. In addition, the fact that butter contains fatty acids such as butyric acid, which is not found in any other fat, causes it to have a popular aroma [7].

The world population is increasing day by day, which necessitates that the basic needs of human beings are produced at a sufficient and qualified level. During the processing of milk, which is among important nutrition products, with various products, a significant part of the nutrients in milk passes on to some by-products such as skim milk, buttermilk, whey, boiled water identified as milk residues. The vast majority of the dairy industry residues is composed of residues resulting from butter and cheese production [8]. Whey is one of the most important by-products of dairy technology. Its composition and properties vary according to the type and quality of the used milk and type of produced cheese [9].

In general, the yellowish-green liquid that remains at the end of the process of processing milk to cheese is called whey. The amount of obtained whey is approximately as 85% of the milk used in cheese production [10].

According to the data of the Turkish Statistical Institute (TÜİK) from the year 2018, total raw milk production in Turkey is 22.120.516 tons. Considering that 34.05% of the raw milk produced in a year is processed into cheese, it can be stated that approximately 753.230 tons of milk is used in cheese making and around 640. 245 tons of whey is obtained [11].

Utilization of whey, which contains about half of the milk dry matter is important both in terms of preventing environmental pollution and the value it contributes to the
economy [12]. Besides the nutritional properties of whey due to its composition, its positive effects on health have been scientifically proven. Today, with the increasing tendency of consumers towards functional foods, the use of whey proteins as additives to various foods has become more widespread. In cheese production centers, the rate of fat in whey released during cheese making differs depending on the technology applied [8]. Nutrient-rich whey has many areas of usage. While creams extracted from whey can be used to standardize milk fat before cheese making, whey can also be used to make butter [13].

By using cream separators, whey can be separated until 0.05% fat is left. The cream obtained in this way can be transformed into butter after heat treatment and acidification with or without adding culture [14].

Free fatty acids (FFAs) are important precursors of catabolic reactions that produce volatile and aroma-contributing compounds [15]. The amount of free fatty acids in dairy products not only has an important effect on the taste and structure of dairy products, but they also have potential effects on nutrition and health as antimicrobial agents [16]. Free fatty acids have strong sensory properties and are important compounds in the formation of flavor and aroma of many dairy products, especially cheese and fermented milk products [17], [18]. Free fatty acids also contribute to texture and functionality as they affect the surface tension and foaming capacity of milk [19], [20].

In this study, it was aimed to determine the effect of some production parameters on the qualities of butter produced from creams extracted from whey and milk.

II. METHODOLOGY

A. Materials

1. Milk and whey

Raw cow’s milk and whey (separated from kashar cheese produced from cow’s milk (Fig. 1) were obtained from the dairy factory producing cheese in the industrial zone between November 2019 and December 2019. The samples were brought to Kafkas University Faculty of Engineering and Architecture Food Engineering Laboratory, and after some samples were taken for a few physical analyses, they were processed in cream.

2. Separator and churner

The Alfa-Laval brand cream separator was used for the separation of raw milk and whey and Minisan brand small-sized churner was used for the churning of creams.

3. Starter Culture

CHN 11 and CHN 22 DVS (Chr. Hansen) coded mesophilic butter culture was used.

B. Methods

Butter production was carried out in three repetitions.

1. Butter production in laboratory conditions. Production of cream butter

Cream with 43% fat obtained by passing raw milk through separator was pasteurized by applying heat at 90 °C for 5 minutes. 2% mesophilic butter starter culture (Chr. Hansen CHN 11 and CHN 22) was added to the cream and it was matured till 5.0 -5.2 pH at 25 °C. Then, it was cooled to the churning temperature, and churning process was done at 8-10 °C. After the churning process was completed, buttermilk was emptied out and the processes of washing and malaxing were performed. Butter taken from the churner was placed in sterile 250-gram light-proof jars and stored at 4±1 °C for 2 days in the refrigerator, then chemical analyses and fatty acid analyses were performed.

2. Butter production from creams obtained from whey

During the production of cheddar cheese (Fig. 1), whey, which is separated during the extraction of the clot, is pasteurized by applying heat for 5 minutes at 90 °C after passing through the cream separator and 2% mesophilic butter starter culture (Chr. Hansen CHN 11 and CHN 22) was added to the cream and it was matured till 5.0 -5.2 pH at 25 °C. Then, it was cooled to the churning temperature, and churning process was done at 8-10 °C. After the churning process was completed, buttermilk was taken out and the processes of washing and malaxing were performed. Butter taken from the churner was placed in sterile 250-gram light-proof jars and stored at 4±1 °C for 2 days in the refrigerator, then chemical analyses and fatty acid analyses were performed.

Acceptance of milk (Cow milk)

Platform tests making

Cleaning of milk

Heating milk (up to 35 °C)

Fermentation (Rennet, clot formation in 60 minutes)

Fracture of the clot

Straining the clot, separating the whey

Suppression of curd

Curd ripening (pH 5-5.2)

chopping of curd

Boiling (2-3 minutes at 72-78 °C)

Kneading and belly tying

Molding (12 hours)

Removing from mold (Pre-ripening)

Storage (3-6 months at 2-8 °C, relative humidity 75%)

Selling

Fig. 1. Kashar cheese production flow chart.

C. Chemical Analyses

The fat contents of raw milk, whey, cream, and butter were detected by the Gerber method [21]-[23] and the
acidity was detected by titration method and the results were stated in % lactic acid [23], [24]. Protein determination in samples was determined by the Kjeldahl method [25]. Protein content was calculated by multiplying the total nitrogen amount by factor of 6.38.

1. Determination of fatty acid composition

Fatty acid composition of the samples was determined according to the fatty acid methyl ester method (FAME) (AOAC 996.01) [26]. According to the method, approximately 0.1 g of fat, which was taken from fat samples obtained as a result of the lipid assay in line with Gerber method, was rinsed with 10 mL of n-hexane and re-mixed with 0.5 mL of 2 N methanolic potassium hydroxide solution. After having been kept in a dark environment for 1-2 hours, 1 µL was taken from the supernatant and directly injected into the gas chromatograph.

2. GC Conditions for fatty acid composition analysis

FAME composition in fat was analyzed by using Restek RTX-2330 capillary column (60 m, 0.25 mm i.d.0.1 µm film thickness, Bellefonte, PA, USA) and flame ionization detector (FID) in a Shimadzu brand gas chromatograph (model QP2010 Plus). The device was given 1 µL of RTX solution. After having been mixed with 0.5 mL of 2 N methanolic potassium hydroxide the samples obtained as a result of the lipid assay in line with fatty acid methyl ester method (FAME) composition in fat was analyzed by using Restek RTX-2330 capillary column (60 m, 0.25 mm i.d.0.1 µm film thickness, Bellefonte, PA, USA) and flame ionization detector (FID) in a Shimadzu brand gas chromatograph (model QP2010 Plus). The device was given 1 µL of injection volume from the sample. Column furnace temperature was increased to 240 °C with 4 °C min-1 increase after being kept for 3 min at 100 °C and was programmed to wait 18 mins at the final temperature. The injection temperature was set to 250 °C and the detector temperature to 255 °C. Helium was used as carrier gas in the device. Injection split ratio was used at 1:80 ratio. To control the GC/FID system, LabSolution computer program was used and FAME mix 37 standard (Restek) as standard. FAME peaks were specified by comparing the chain lengths and retention times of the fatty acids specified in FAME standard.

D. Statistical Analyses

In the evaluation of the obtained results, the mean value and standard deviation of the samples were determined by using the SPSS package program and the differences between the samples were examined by the Duncan test.

III. RESULTS AND DISCUSSION

A. Study Results

The results of fat, protein and titration acidity of cow's milk, whey, cream, and butter are presented in Table I. The fatty acids composition belongs to the cream and whey butter samples is presented in Table II and Table III.

### Table I: Results of Chemical Analysis of Milk, Whey, Cream and Butter Used in Butter Production (n=3)

| Characteristic          | Milk   | Whey   | Cream | Milk | Whey butter | Cream butter |
|-------------------------|--------|--------|-------|------|-------------|--------------|
| Titratable acidity (%)  | 0.17±0.00 | 0.13±0.01 | 0.22±0.01 | 0.26±0.00 | 0.26±0.00 | 0.25±0.01    |
| Fat                     | 3.50±0.14 | 0.60±0.19 | 39.0±0.34 | 43.0±0.35 | 80.0±0.46 | 84.0±0.42    |
| Protein                 | 3.30±0.19 | 0.68±0.03 | 0.93±0.12 | 0.54±0.03 | 0.51±0.02 | 0.58±0.00    |

### Table II: Fatty Acid Content of Cream and Butter Made From Milk and Whey (%)

B. Discussion

The fat values of cow’s milk were lower than those determined by [7] and [27] in the milk used in butter production, the acidity value was similar to the value determined by [7] and higher than the value determined by [27] in the milk used in churned butter production.

In butters presented to consumption in Adana, the average fat content was detected as 79.5% and the titration acidity value was detected as 0.16% in l.a % [28], [29] stated that the fat content in butters presented to consumption in Trabzon is 79.5-87.5% and the acidity value is 0.22-1.47% l.a. [30] detected that the fat content of butters purchased from the markets in Van was between 76-83%.

The amount of fat detected in cream butters is within the range of values determined by [29] and higher than the values determined by [30] and [28] in butter samples. It is thought that factors such as the composition of the used milk, the cream-making method, the fat content of the creams and the butter-processing method are effective in differences between butter samples.

The acidity value detected in cream butter differs from the values of other researchers. Increases and decreases in the amount of dry matter cause a change in the titration acidity of the milk [31]. The fact that the fat-free dry matter elements are transferred to the buttermilk to a large extent during the churning process is one of the factors that cause the low titration acidity of butter.

Fat and protein values of butter samples made from whey are lower than the amount detected by [13] in the butter that they produced from whey. It can be stated that factors such as the fat content of the whey and the butter-processing method play a role in the differences between whey butter samples.

Ten saturated and 7 unsaturated fatty acids were detected in butters. The most common fatty acids are palmitic, stearic, myristic, and oleic acid.

The fact that palmitic, stearic, and myristic acid are the most common fatty acids found in butter has been reported by other researchers, too [2], [27], [32]. Oleic acid, which is the main unsaturated fatty acid in milk, is used as an energy source and in the reserves of body fat. It is believed that the consumption of monounsaturated fatty acids, such as oleic acid, which is one of the precursors of very long-chain fatty acids used in the structure of brain tissue, particularly in myelin, and relatively neutral in terms of cardiovascular aspect, is useful in reducing low-density lipoprotein (LDL) (bad cholesterol) levels in the blood [33], [34].

69.56% of fatty acids detected in cream butter was composed of saturated fatty acids (SFAs) (47.86% palmitic, 17.30% stearic, 17.29% myristic acid), 29.00% was composed of monounsaturated fatty acids (MUFAs), 2.12% was composed of polyunsaturated fatty acids (PUFAs).

[35] detected as 66.01% ΣSFAs, 25.62% ΣMUFAs and 1.47 ΣPUFAs in butter made from creams obtained from cow’s milk.

[30] found the values as ΣSFAs 61-74 g/100g, ΣMUFAs 1116-7061 mg/kg and ΣPUFAs 40-667 mg/kg in the butters they collected from the markets in Van.

67.77% of fatty acids detected in whey butter was composed of saturated fatty acids (SFAs) (49.48% palmitic, 17.72% stearic, 15.97% myristic acid), 30.33% was composed of monounsaturated fatty acids (MUFAs), 2.07% was composed of polyunsaturated fatty acids (PUFAs). Total saturated fatty acids and polyunsaturated fatty acid values of whey butters were found lower than cream butters, but monounsaturated fatty acid values were found higher.

In butter samples, total short-chain fatty acid amounts in whey butter were detected as 3.59%, medium-chain fatty acid amounts as 18.54%, long-chain fatty acid amounts as 77.04%, very long chain fatty acids 0.86% and in cream.

Butter; total short-chain fatty acid amounts were detected as 3.61%, medium-chain fatty acid amounts as 20.56%, long-chain fatty acid 73.74% and very long chain fatty acids amounts as 0.91% (Table III).

In the study conducted to determine the fatty acids of Trabzon butters; the total short-chain fatty acid levels of the samples were detected as 1.43-2.17%, medium-chain fatty acid levels as 0.09-12.00%, long-chain fatty acids as 0.01-34.24% and very long chain fatty acid 0.02-1.01% [2].

[30] detected the short-chain fatty acids as 37-4593 mg/kg, medium-chain fatty acids as 348-4499 mg/kg and long-chain fatty acids as 2027-17470 mg/kg in the butters presented for consumption in Van.

The short-chain fatty acid rates of whey butter and cream butter samples are higher than the values detected by [2] in Trabzon butter and lower than the values determined by [30] in the butters presented for consumption in Van. The amount of medium-chain and long-chain fatty acids is in the value range detected by [2] in Trabzon butter.

The amounts of palmitic, stearic, oleic acid and the amount of unsaturated fatty acids in whey butter are higher than those of cream butter. It is thought that this difference may be effective in the enzymes of the microorganisms that develop in the cold during the waiting process of the cream becoming active in the later phases and accelerate the lipolysis [36].

The values detected in experimentally produced butter
samples are higher than the ones detected by [35] and [30]. Factors such as the composition of raw material milk used in butter production, the fat content of the cream, the buttermaking method and the production period constitute the differences between the results obtained. The amount of long-chain fatty acids in both butter samples is higher than short and medium-chain fatty acids.

The water solubility of fatty acids is related to the number of carbons. As the number of carbon increases, volatility and water solubility decreases and carbon fatty acids of which carbon number is 10 more are insoluble in water [37, 38]. Thus, fatty acids which are soluble in the fatty phase don't segregate with the buttermilk and the concentration of the high molecular fatty acids at a higher level in the fatty phase of the fatty acid compared to short-chain fatty acids is the main cause of the detected increase.

It was found that the short-chain fatty acids rates were lower in the total fatty acids in butters. It is thought that this situation results from the dissolution of nearly all of the butyric acid and partially caproic acid, which are among the fatty acids, in water.

[39] stated that the low rates of short-chain fatty acids in the total fatty acids in the butters presented for sale in Urfa may result from the dissolution of butyric acid and partially the caproic acid in water or vaporizing with water vapor.

The amount of high molecular saturated fatty acids detected in the samples is higher than the sum of both low molecular fatty acids and unsaturated fatty acids. It is thought that the distribution of fatty acids in fat globules is effective in obtaining this result. The high molecular fatty acids exhibit a sequence associated with the membrane of the fat globules. The fact that this fraction is in solid form at room temperature gives the fat globules a certain resistance. Low molecular saturated fatty acids and unsaturated fatty acids found in liquid form at room temperature are located at the center of the fat globulin [36].

AI [40] states that the ratio of unsaturated fatty acids and short-chain fatty acids in butter obtained from whey separated from Ras and Mozzarella cheese is higher than cream butter. In particular, considering that the linoleic acid ratio increased by more than 50% in both whey fats provides an advantage to the nutritional values of these fats, as well as the risk of atherosclerosis caused by the consumption of animal fats containing high saturated long chain fatty acid.

In this study, it was determined that the ratio of unsaturated fatty acids in butter made from whey is higher than butter made from milk cream, and the ratio of saturated fatty acids is lower than butter made from milk cream. Our results are in agreement with the results of this researcher.

IV. CONCLUSIONS

In conclusion, 10 saturated and 7 unsaturated fatty acids were detected in cream and whey butter samples. The most common fatty acids were palmitic, stearic, myristic and oleic acid.

The amount of free fatty acids in dairy products not only has an important effect on the taste and structure of dairy products, but they also have potential effects on nutrition and health. Fatty acid composition of milk may vary due to reasons such as type of the milk, genetic and physiological factors of animals, lactation, season, feed, and geographic location. Therefore, the fatty acid content of butter, like other dairy products, is highly affected by these factors. The concentration of short-chain fatty acids such as butyric, caproic, caprylic and capric acids can have an impact on the flavor properties of butter. The variety of aroma components that affect consumer appreciation is an indication of product quality.

Whey is an important dairy by-product, and about 85% of the milk used in cheese production is obtained from whey.

Considering the factors such as the high nutritional value of whey in terms of its composition and its disposal without utilization leading to economic loss along with causing environmental pollution, these dairy products should be evaluated in order for dairy production to be profitable, to reduce the cost and to prevent waste. Since the endurance period of skimmed milk powder is longer than that of fatty milk powder, during whey powder production, whey cream can be separated and processed into whey, and the cream separated during the process can be an alternative raw material in butter production.

When the butter made from whey cream and the butter made from cream are compared, not much difference is observed. It can be said that whey butter is an aromatic product because it contains fatty acids which have an important effect on the taste and aroma of milk and dairy products.

Also, we can state that since butter production with whey cream can be less costly than butter production with sweet cream, it can be used as an alternative raw material in butter production.

Cetinkaya A. is an asistant professor at the Department of Food Engineering, Kafkas University, Kars, Turkey. More recently, she has worked in the field of fatty acids and flavor compounds of dairy products. Her research interests also include the production and chemistry of different types of cheese, their biochemistry, lactic acid bacteria in dairy products, traditional cheeses and their properties, and packaging materials in cheeses.
