The newly observed $X, Y, Z$ exotic states are definitely not in the standard $Q\bar{Q}$ structures, thus their existence composes a challenge to our understanding on the fundamental principles of hadron physics. Therefore the studies on their decay patterns which are determined by the non-perturbative QCD will definitely shed light on the concerned physics. Generally the four-quark states might be in a molecular state or tetraquark or their mixture. In this work, we adopt the suggestion that $Y(4630)$ is a charmonium-like tetraquark made of a diquark and an anti-diquark. If it is true, its favorable decay mode should be $Y(4630)$ decaying into an open-charm baryon pair, since such a transition occurs via strong interaction and is super-OZI-allowed. In this work, we calculate the decay width of $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$ in the framework of the quark pair creation (QPC) model. Our numerical results on the partial width computed in the tetraquark configuration coincide with the Belle data within a certain error tolerance.

I. INTRODUCTION

In 2007, the Belle collaboration reported that a $J^{PC} = 1^{−}$ resonance peak $Y(4630)$ with mass $M = 4634^{+12}_{−11}$ MeV and width $\Gamma = 92^{+41}_{−25}$ MeV appeared at the invariant mass spectra of the $e^+e^- \rightarrow \Lambda_c^+ \Lambda_c^−$ channel [1].

Besides an interpretation that the observed $Y(4630)$ is the $5^1S_1$ charmonium state [2, 3], there are many alternative suggestions for the observed peak, for example, $Y(4630)$ was considered to be induced by a threshold effect instead of being a genuine resonance [4], then it was also interpreted as a molecular state made of $\psi(2S)$ and $f_0(980)$ by another theoretical physics group [5]. Among those proposals, the suggestion that $Y(4630)$ is a tetraquark state is more favorable [6, 7]. In Ref. [6], the $Y(4630)$ is identified as the ground state with its orbital angular momentum $L = 1$. It is noted that the mass and width of $Y(4630)$ are consistent within errors with those for the $Y(4660)$ state ($M = 4652 \pm 10 \pm 8$ MeV, $\Gamma = 68 \pm 11 \pm 1$ MeV), which is found in the invariant mass spectrum of $\psi(2S)\pi^+\pi^−$ by the Belle collaboration [8, 9]. By analyzing the $\Lambda_c^+\bar{\Lambda}_c^-$ and $\psi(2S)\pi^+\pi^−$ spectra, Cotugno et al. suggested that the $Y(4630)$ and $Y(4660)$ could be the same tetraquark state, and is the first radial excitation of the $Y(4360)$ with $L = 1$ [7].

In fact, $Y(4630)$ as a $[cq][\bar{c}\bar{q}]$, tetraquark would more likely decay into charmed baryon-pair [5, 7], and the ratio $BR(Y \rightarrow \Lambda_c \bar{\Lambda}_c)/BR(Y \rightarrow \psi(2S)\pi^+\pi^-)$ = 25 ± 7 [7] suggests that the double baryon decay mode $\Lambda_c \bar{\Lambda}_c$ is strongly preferred.

However, there definitely may exist other decay modes beside of the $\Lambda_c \bar{\Lambda}_c$ pair, such as $D\bar{D}$, $D^*\bar{D}^*$, $D^*\bar{D}^*$, $J/\psi\eta$, $\psi(2S)\eta$, etc. Such processes occur via color rearrangements which in principle can be depicted by hadronic loops even though the propagators in the loops do not correspond to real color-singlet particles (see in text), so they suffer from a loop suppression. Even though the most promising tetraquark candidate $Z(4430)^+$ decays into the $[cq][\bar{c}\bar{q}]$ mode $\psi(2S)\pi^+\pi^−$ [10–13] with a broad width $\Gamma = 172 \pm 13$ MeV, this case is very different from $Y(4630)$. Since its mass is below the $\Lambda_c \bar{\Lambda}_c$ threshold it would overwhelmingly decay into open-charmed mesons. For $Y(4630)$ case, as its mass is above the double-baryon threshold, the strong decay of such tetraquark state is OZI-super allowed. Therefore, following the suggestions given by other groups here we will assume that the decay mode $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$ would be dominant, namely this partial width could be at the same order of the total width.

A tetraquark is assumed to be made of the diquark-antidiquark $[cq][\bar{c}\bar{q}]$, where $q$ is a light quark either $u$ or $d$ and $[cq]$ resides in a color anti-triplet whereas $[\bar{c}\bar{q}]$ is in a color triplet (in later calculations we do not distinguish between $u$ and $d$ at all). In this work, we suppose that $Y(4630)$ is a tetraquark in the dynamic picture suggested by Brodsky et al. [14]. In the tetraquark a diquark and an anti-diquark are bound together via the QCD confinement, but are separated by a substantial distance once they are created. Thus the $Y(4630)$ state can be considered as a two-body meson-like state. The picture we adopt in this work is slightly different from that proposed by Maiani et al. [6, 15], where the authors studied the tetraquark states by means of their spin structure of a Hamiltonian formalism [16], in fact, the two pictures are in principle consistent. Under this assignment, we study the strong decay of $Y(4630)$ by computing the width of $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$ in the quark pair creation (QPC) model. The corresponding reaction mechanism is that first the diquark-antidiquark bound state is dissociated into a “free” diquark-antidiquark system and a light quark-antiquark pair is created from the vacuum, then the quark and anti-quark would join the diquark and antidiquark respectively to constitute a baryon-anti-baryon pair. Indeed, this association can be viewed as that due to soft gluon emission a light-quark pair is created and the soft gluons tear off
the diquark-antidiquark bound state, then by absorbing light quark and antiquark respectively they transit into color singlet baryons. Moreover, $M_{\Lambda} + M_{\bar{\Lambda}}$ is only slightly below 4630 MeV, so that a suppression induced by matching different momenta as appearing at similar hadronic processes, does not exist. Surely the whole dissociation process is governed by non-perturbative QCD, so that one needs to introduce a few phenomenological factors which can only be obtained by fitting available data.

The paper is organized as follows: after this introduction, we calculate the rate of $Y(4630)$ decaying into the $\Lambda_{c}\bar{\Lambda}_{c}$ pair in section II A & II B and perform a numerical analysis in Sec. II C. The other decays of $Y(4630)$ are discussed in Sec. III. Sec. IV is devoted to our summary.

II. THE $Y(4630) \rightarrow \Lambda_{c}\bar{\Lambda}_{c}$ STRONG DECAY

In this work, we use the two-body wave function for the diquark-antidiquark bound system $Y(4630)$, since the constituents (diquark and antidiquark) are treated as two point-like color sources. In this structure, the diquark $Q\bar{q}$ of color-anti-triplet in the tetraquark is in analog to a heavy $\bar{Q}$ residing in a common meson $Q\bar{Q}$ while $Q\bar{Q}$ is similar to $Q$ by the same color configuration.

The spin wave functions of a $Y(J^{PC} = 1^{-+})$ state with $L = 1$ in the basis of $[S_{gq}, S_{\bar{g}\bar{q}}, S_{\text{total}}, L]_{J=1}$ can be assigned in four distinct states as [6]

$$
\begin{align*}
Y_1 &= |0, 0, 0, 1\rangle_1, \\
Y_2 &= 1/ \sqrt{2} (|0, 0, 1, 1\rangle_1 + |0, 1, 1, 1\rangle_1), \\
Y_3 &= |1, 0, 0, 1\rangle_1, \\
Y_4 &= |1, 1, 2, 1\rangle_1.
\end{align*}
$$

In the following, we present all the details of calculating $Y(4630) \rightarrow \Lambda_{c}\bar{\Lambda}_{c}$ in the QPC model.

A. Implementation in the QPC model

The QPC model [17–23] has been widely applied to calculate the rates of Okubo-Zweig-Iizuka (OZI) allowed strong decays [24–37], which obviously compose the dominant contributions to the total widths of the concerned hadrons.

As indicated in the introduction, we suppose $Y(4630)$ as a tetraquark in the diquark-antidiquark structure, thus in our case, the decay of $Y(4630)$ is a dissociation process where the diquark and antidiquark bound state is loosened by a quark-antiquark pair which is created in vacuum. Concretely, the quark and antiquark of the pair excited out from the vacuum would join the diquark and antidiquark respectively to compose a $\Lambda_{c}\bar{\Lambda}_{c}$ pair, and the process is graphically shown in Fig. 1.

The quantum number of the created quark pair is $0^{++}$ [17, 18]. In the non-relativistic limit, the transition operator is expressed as

$$
T = -3\gamma \sum_{m} \langle 1n; 1 - m|0 0 \rangle \int d\mathbf{k}_5 d\mathbf{k}_6 \delta^3(\mathbf{k}_5 + \mathbf{k}_6)
$$

$$
\times \mathcal{Y}_{lm} \left( \frac{\mathbf{k}_5 - \mathbf{k}_6}{2} \right) \chi_{1,m}^{66} \varphi_0^{56} \omega_0^{56} d_{i}^{j}(\mathbf{k}_5) b_{ij}^{*}(\mathbf{k}_6),
$$

where $i$ and $j$ are the SU(3)-color indices of the created quark and anti-quark. $\varphi_0^{56} = (ud + dd + ss)/\sqrt{3}$ and $\omega_0^{56} = \delta_{ij}$ are for flavor and color singlets, respectively. $\chi_{1,m}^{66}$ is a spin triplet. Here the indices 5 and 6 distinguish between the quark and antiquark respectively as shown in Fig. 1. $\mathcal{Y}_{lm}(\mathbf{k}) \equiv |\mathbf{k}|^{l} Y_{lm}(\theta_{k}, \phi_{k})$ denotes the $l$th solid harmonic polynomial. $\gamma$ is a dimensionless constant for the strength of quark pair creation from vacuum and is fixed by fitting data.

In the dynamical picture of tetraquark, the (anti)diquark is considered to be a point-like color source, then the two-body wave function(meson-like) should be a good approximation to describe the inner structure of $Y(4630)$. Including the color, spin, flavor and the spatial parts, the wave function is written as

$$
|Y_{\gamma}^{2S+1L} J \gamma J_{\gamma} M_{\gamma} \rangle(k_{Y})
$$

$$
= \sqrt{2E_{Y}} \sum_{M_{S_{Y}} M_{S_{F}}} \langle L_{Y} M_{L_{Y}} S_{Y} M_{S_{Y}} |J \gamma J_{\gamma} M_{\gamma}\rangle
$$

$$
\times \int d\mathbf{p}_1 d\mathbf{p}_2 \delta^3 (\mathbf{K}_{Y} - \mathbf{p}_1 - \mathbf{p}_2) \psi_{\gamma}^{[12][34]} \Omega_{Y}^{[12][34]} |[q_{1} q_{2}] (p_{1}, p_{2}) \rangle,
$$

where we use the (super)subscript 1~4 to mark the (anti)quark in the tetraquark as clearly shown in Fig 1. $K_{Y} = S_{\gamma}^{[q_{1} q_{2}]}$, $S_{\gamma}^{[\bar{q}_{1} \bar{q}_{2}]}$ is the total spin. $J_{Y} = L_{Y} + S_{Y}$ denotes the total angular momentum of $Y(4630)$.

We also consider the diquark-quark picture [38–42] for the $\Lambda_{c}$ baryon in where the internal degrees of freedom of the
diquark are neglected as in the tetraquarks, then we have
\[
\left| \Lambda_c(M_{\Lambda_c}, p_{\Lambda_c}) \right| = \sqrt{2E_{\Lambda_c}} \int dp_1 dp_2 d|k_{\Lambda_c}| d^3(k_{\Lambda_c} - p_1 - k_3) \\
\times \Psi_{\Lambda_c}(p_1, k_3) \chi_{\Lambda_c} \Psi_{\Lambda_c}^{1123} \chi_{\Lambda_c} \Psi_{\Lambda_c}^{1123} \\
\times \left\{ \left[ q_1 q_2 \right] (p_1) q_3 (k_3) \right\},
\]
where the (super)subscripts in the expressions correspond to the constituent quark and the diquark, and $\Lambda_c$ is the 3-momentum of $\Lambda_c$, $p_1(k_3)$ is the 3-momentum of the diquark (quark). The quantum numbers of $\Lambda_c$ are known as $J^P = \frac{1}{2}^+$ and $L = 0$, so we only use $M_{\Lambda_c} (= M_{I_{\Lambda_c}})$ to label the spin projection state.

The wave functions respect the normalizations conditions
\[
\langle Y(K_Y) | Y(K_Y') \rangle = 2E_Y \delta^3(K_Y - K_Y'),
\]
\[
\langle \Lambda_c(K_{\Lambda_c}) | \Lambda_c(K_{\Lambda_c}') \rangle = 2E_{\Lambda_c} \delta^3(K_{\Lambda_c} - K_{\Lambda_c}').
\]

For $Y(4630) \to \Lambda_c + \bar{\Lambda}_c$ process, the transition hadronic matrix element is written as
\[
\langle \Lambda_c, \bar{\Lambda}_c | S | Y(4630) \rangle = 1 - i2\pi\delta(E_f - E_i) \langle \Lambda_c, \bar{\Lambda}_c | T | Y(4630) \rangle.
\]
In the center of the mass frame of $Y(4630)$, $K_Y = 0$ and $K_\Lambda = -K_{\bar{\Lambda}} = K$. Then, we have
\[
\langle \Lambda_c, \bar{\Lambda}_c | T | Y(4630) \rangle = -3\gamma \sqrt{8E_{\Lambda_c}E_{\Lambda_c'}} \\
\times \sum_{M_{\Lambda_c}M_{\bar{\Lambda}_c}m} \sum_{M_{K_{\Lambda_c}}M_{K_{\bar{\Lambda}_c}}} \left( 1 \| 1 \| 0 0 \right) \\
\times \langle S_{\Lambda_c} M_{\Lambda_c} S_{\bar{\Lambda}_c} M_{\bar{\Lambda}_c} \rangle \langle S_{K_{\Lambda_c}} M_{K_{\bar{\Lambda}_c}} \rangle \langle S_{K_{\bar{\Lambda}_c}} M_{K_{\Lambda_c}} \rangle \\
\times \langle \Lambda_c | \bar{\Lambda}_c | Y(4630) \rangle \langle \bar{\Lambda}_c \Lambda_c | \bar{\Lambda}_c \Lambda_c \rangle \\
\times \langle \bar{\Lambda}_c \Lambda_c | \bar{\Lambda}_c \Lambda_c | Y(4630) \rangle \\
\times \langle \bar{\Lambda}_c \Lambda_c | \bar{\Lambda}_c \Lambda_c | Y(4630) \rangle \\
\times \langle \bar{\Lambda}_c \Lambda_c | \bar{\Lambda}_c \Lambda_c | Y(4630) \rangle.
\]

The expressions of Eq. (6) for $Y_{1,2,3,4}$ states are explicitly written out in terms of $I^{M_{I_{\bar{\Lambda}_c}}, m_{I_{\bar{\Lambda}_c}}}(K)$ as listed in the Appendix A. The spatial integral $I^{M_{I_{\bar{\Lambda}_c}}, m_{I_{\bar{\Lambda}_c}}}(K)$ manifests an overlap between the spacial parts of the initial state (including the created light quark pair) and the final state, and is expressed as
\[
I^{M_{I_{\bar{\Lambda}_c}}, m_{I_{\bar{\Lambda}_c}}}(K) = \int dp_1 dp_2 d|k_{\bar{\Lambda}_c}| d^3(k_{\bar{\Lambda}_c} - p_1 - k_3) \\
\times \delta^3(p_1 + p_2) \delta^3(K_{\bar{\Lambda}_c} - p_1 - k_3) \\
\times \delta^3(k_3 - k_6) \Psi_{\Lambda_c}(p_1, k_3) \bar{\Psi}_{\Lambda_c}(p_2, k_6) \\
\times \Psi_{\sigma_1 \Lambda_c} \left( \frac{p_1 - p_2}{2} \right) \bar{\Psi}_{\Lambda_c} \left( \frac{k_3 - k_6}{2} \right) \\
= \int dp_1 \Psi_{\Lambda_c}(p - \mu K) \bar{\Psi}_{\Lambda_c}(-p + \nu K) \\
\times \Psi_{\sigma_1 \Lambda_c} \left( \frac{p - \mu K}{2} \right) \bar{\Psi}_{\Lambda_c} \left( \frac{k_3 - k_6}{2} \right),
\]
where $\mu = m_{[cq]}(m_{[cq]} + m_\Lambda)$ and $\nu = m_{[cq]}(m_{[cq]} + m_\Lambda)$. Following the literature in this field, we employ the simple harmonic oscillator (SHO) wavefunctions to stand for the spacial parts of the two-body wave functions of $Y(4630)$. Their explicit forms are collected in the appendix B. The wavefunction of $\Lambda_c$ will be considered in the next section.

With the transition amplitude given in Eq. (6), the matrix element can be rewritten in terms of the helicity amplitude $M^{M_{\Lambda_c}, M_{\bar{\Lambda}_c}}$ as
\[
\langle \Lambda_c, \bar{\Lambda}_c | T | Y(4630) \rangle = \delta^3(K_{\Lambda_c} + K_{\bar{\Lambda}_c} - K_Y) M^{M_{\Lambda_c}, M_{\bar{\Lambda}_c}}.
\]

The decay width of $Y(4630) \to \Lambda_c \bar{\Lambda}_c$ is then
\[
\Gamma_Y = \frac{\pi^2 |K|}{M^2_Y} \frac{1}{2J + 1} \sum_{M_{\Lambda_c}M_{\bar{\Lambda}_c}} \left| M^{M_{\Lambda_c}, M_{\bar{\Lambda}_c}} \right|^2,
\]
where $|K|$, as aforementioned, is the 3-momentum of the final states in the center of mass frame.

B. Baryon wavefunction

The charmed baryon $\Lambda_c$ is considered as the $[cq]q$ picture in our scenario, then a two body wavefunction, which can be gained by solving the Schrödinger equation, could be a reasonable approximation.

For our concrete calculation, we employ a non-relativistic Cornell-like potential where the concerned free parameters are fixed by fitting the mass spectra of charmed baryons. By solving the Schrödinger equation we obtain the wave function of $\Lambda_c$. The general Hamiltonian of a diquark-quark system (i.e. a two body system) can be written as
\[
H = \frac{p_{[cq]}^2}{2m_{[cq]}} + m_{[cq]} + \frac{p_q^2}{2m_q} + m_q + V(r),
\]
where the $m_{[cq]}(p_{[cq]})$ and $m_q(p_q)$ are the masses(3-momenta) of the diquark $[cq]$ and quark $q$ respectively.

It is worth of pointing out that in literature, the diquark-quark structure might be different, namely the two light quarks make a light diquark and the heavy quark stands as a color source. Instead the baryon still might be in $[Qq_1q_2]$ structure [43], especially in our case the diquark (anti-diquark) does not have time to recombine into $Q_1(q_1q_2)$ by color rearrangement, namely the original diquark structure would remain to make a color singlet baryon by absorbing a light quark. The interaction potential is
\[
V(r) = -\frac{4\alpha_s}{3} \frac{\alpha_s}{r} + br^* + c,
\]
where $-4/3$ is the color factor specific to $3\bar{3}$ attraction, $b$ is the string tension and $c$ is a global zero-point energy. Here we take the $br^* + c$ part as the confinement which is slightly different form the usual Cornell $br^* + c$ potential. $\alpha_s$ is the phenomenological strong coupling constant.

In this work, since only the wave function of $\Lambda_c^+(2286)$ which is in S-wave is needed, the hyperfine interactions including the spin-spin interaction, the spin-orbit interaction and the color tensor interaction [30] are not included.
With the diquark mass $m_{c_{qg}} = 1.86$ GeV which is calculated by the QCD sum rules [44] and the light constituent quark mass $m_q = 0.33$ GeV, the parameters are fixed to be: $\alpha_s = 0.45, b = 0.135$ GeV$^2, \kappa = 0.84, c = 0.333$ GeV. Here, as theoretical inputs, we ignore possible inaccuracies of the parameters.

The fitted spectra are presented in Table. I, and a comparison with the experimental data and other theoretical predictions in literature are also listed in the table. The radial wave function of $\Lambda_c(2286)$ is plotted in Fig. 2.

TABLE I: The fitted spectra of charmed baryons with different quantum numbers, including a comparison with the experimental data and other theoretical predictions in literature. Here, the masses of the baryons are in units of MeV.

| States       | PDG [45] | This work | Ref. [30] | Ref.[46] | Ref.[47] |
|--------------|----------|-----------|-----------|-----------|-----------|
| $|S, 1/2^+|$ 2286.46 | 2286.1    | 2265      | 2286      | 2286      |
| $|S, 1/2^-$ | 2766.6   | 2768.5    | 2775      | 2769      | 2766      |

We first compute the decay width of $Y(4630) \rightarrow \Lambda_c\bar{\Lambda}_c$ with the $n_r = 1$ assignment. The left panel of Fig. 3 shows the dependence of the calculated width $\Gamma$ on $R_T$ within a range (1 ~ 6) GeV$^{-1}$. The colored curves correspond to the four spin states $Y_{1,2,3,4}$ which are marked on the figures. As discussed before, the decay mode $Y(4630) \rightarrow \Lambda_c\bar{\Lambda}_c$ should be dominant, so we compare this calculated partial width with the total width of $Y(4630)$. In the plot one can find the predicted width for the $Y_{1,2,3,4}$ assignments do coincide with the data and the error band of 1$\sigma$ (gray region) given by the Belle collaboration ($\Gamma = 92^{+41}_{-32}$ MeV).

For the $Y_3$ case the figure shows that the values of the curves are obviously lower than the data $\Gamma = 92^{+41}_{-32}$ MeV. This suppression is caused by the relatively small overlap between the spin wave functions of initial and final states (one can see the appendix A for some details). Therefore it is concluded that the data do not favor $Y(4630)$ to be a ground state with $Y_3$ spin structure.

Next, as $Y(4630)$ being assigned as the first radial excitation state, our numerical results are shown at the right panel of Fig. 3 for all the four spin assignments. The results show that the $Y_{1,2}$ states can meet with the experimental data as long as $R_T$ lies in a range of 1.5 ~ 3 GeV$^{-1}$ and/or around 5 GeV$^{-1}$. The values correspond to the $Y_4$ state are slightly lower, however, they are still of the same order as the total width. Again, for $Y_3$ state, the situation is similar to that for $n_r = 1$, the computed width are much below the data.

In a brief summary, our numerical results indicate that within certain regions of the parameter $R_T$, the partial width of $Y(4630) \rightarrow \Lambda_c\bar{\Lambda}_c$ can be comparable with the Belle data. Given the fact that the peak of $Y(4630)$ has only been observed at the invariant spectrum of $\Lambda_c\bar{\Lambda}_c$, one is tempted to assume that the $\Lambda_c\bar{\Lambda}_c$ mode dominates the decay of $Y(4630)$.
Moreover our calculation indicates that this predicted partial width is comparable with the total width of $Y(4630)$. This consistency supports the assumption that the $Y(4630)$ is a P-wave tetraquark in the diquark-antidiquark configuration and decays mainly into double charmed baryons. We will make more discussions on this issue in the next section.

Also $Y(4630)$ could be in either the radial ground state with $n_t = 1$ or the first excited state with $n_t = 2$. In other words, the present data cannot rule out any of the two possible configurations. So definitely it needs to be studied with more experimental information in the future to decide the more accurate nature of $Y(4630)$, so as the spin structures.

III. DISCUSSIONS ON OTHER DECAY MODES

As discussed in the introduction, beside the dominant $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$, there may exist other decay modes, such as $D\bar{D}^*$, $D^*\bar{D}^*$, $\psi(2S)\pi^+\pi^-$, $\psi(2S)\eta$, etc. For instance, if one considers the both observed $Y(4630)$ and $Y(4660)$ to be tetraquark states [7], $Y(4630(4660)) \rightarrow \psi(2S)\pi^+\pi^-$ occurs through a quark rearrangement process.

For the tetraquark structure, this decay mode requires a quark-antiquark rearrangement which is also a color exchange process. In the process a quark and an antiquark which belong to different clusters are switched round to produce the final states.

In the figure 4, tracing the diquark (antiquark) flow lines, one can draw an effective hadronic Feynman diagram as a diquark (scalar or vector) which brings a color-content (color-triplet 3 or anti-triplet $\bar{3}$) is exchanged between the diquark $[cq]$ and antidiquark $[c\bar{q}]$, and results in the final state to be in color-singlet.

![FIG. 4: Effective diagram for the decay of $Y(4630)$ to $\psi(2S)\eta$, etc.](image)

In figure, such processes occur via a hadronic loop, therefore is suffering from a loop suppression. This Feynman diagram is similar to the final state interaction where all lines corresponding to (no matter inside the loop or outside finally produced hadrons) color-singlet hadrons, thus only difference between the quark rearrangement and final state interaction is their color configurations. But both of them are suppressed. In our another paper, we estimated the rates of $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c \rightarrow pp, DD, D\bar{D}^*, \pi\pi, K^+K^-$ etc. through hadronic rescattering and found that such as final states could be observed by much more accurate measurements [49]. Similarly, we may conjecture that the color-re-arrangement which proceeds along similar way should have comparable rates.

In fact, such quark exchange mechanism was investigated by some authors for meson decays [50–52], but since it is completely induced by the non-perturbative QCD effect, the estimate in terms of the present theories cannot be accurate, or at the best can be valid to the order of magnitude if one can find an appropriate model to carry out numerical computations.

IV. SUMMARY

To evaluate the hadronic matrix elements which are governed by the non-perturbative QCD, phenomenological models are needed. For the OZI-allowed strong decays, the QPC model, flux tube model, QCD sum rules and lattice QCD, etc. have been successfully used to estimate the decay rates, even though except the lattice calculation none of them can be directly derived from quantum field theory. We are assured that all of those models have certain reasonability and they are in parallel somehow. In this work, we employed the QPC model to study the strong decay of $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$.

First we assume that $Y(4630)$ is a tetraquark which is a bound state of a diquark and an anti-diquark. As its mass is slightly above the threshold of two charmed baryons, it would favorably decay into $\Lambda_c \bar{\Lambda}_c$ pair, therefore the fact that $Y(4630)$ is only observed at the invariant spectrum of $\Lambda_c \bar{\Lambda}_c$ is understandable.

There could be different quantum structures for the diquark-anti-diquark bound state, and we try to assign it with various radial quantum numbers and spin assignments and then calculate the decay width of $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$ in all possible cases.

The numerical results show that, within certain parameter range of $R_y$, one can gain proper decay width $\Gamma_y$ that agrees with the experimental data if we assign $Y(4630)$ as either the radial ground state $n_t = 1$ or the first radially excited state $n_t = 2$. Whereas for the case of $Y_3$, the obtained partial width are suppressed by the small overlap between the spin wave functions, so the $Y_3$ spin state is ruled out. Our analysis provides a strong support to the postulate that $Y(4630)$ is the diquark-antidiquark bound state whose mainly decay channel should be $Y(4630) \rightarrow \Lambda_c \bar{\Lambda}_c$.

We are looking forward to getting more information from the Belle-II, LHCb experiments, especially we will pay more attention to, such as $D\bar{D}, D\bar{D}^*, D^*\bar{D}^*, \psi(2S)\pi^+\pi^-$, $\psi(2S)\eta$ etc. decay modes, which may shed more light on the structure of $Y(4630)$. In particular, we suspect if there is a mixing between the tetraquark and molecular states to result in $Y(4630)$ and $Y(4660)$, it would be an interesting picture. Indeed in the near future, with the accumulated data at various accelerators, our understanding on the XYZ states will be improved and the observations of new states are expected.

Note added. When we make changes to our manuscript, we notice that another work [53] which suggests to use $Y(4630)$ as a window to the landscape of tetraquarks appears, by J.
Sonnenshein and D. Weissman, and we cite it at the end of this modified manuscript.

Acknowledgement

We would like to thank Prof. Hai-Yang Cheng for helpful and inspired discussions. We would also thank Kan Chen, Yuan Sun and Hao-Kai Sun who help us with programming for the numerical computations. This project is supported by the National Natural Science Foundation of China under Grants No. 11375128 No. 1135009, No. 11222547, No. 11175073. Xiang Liu is also supported by the National Youth Top-notch Talent Support Program ("Thousands-of-Talents Scheme").

Appendix A: Explicit formulae for the matrix elements

\[ M_{M_{I\lambda \kappa},M_{I\lambda \kappa}} = -\frac{1}{\sqrt{6}} \gamma \sqrt{E_1 E_2 E_3} M_{M_{I\lambda \kappa},M_{I\lambda \kappa}} \]  
(A1)

For spin state \( Y_1 \):

\begin{align*}
  \mathcal{A}^{z+}_{1} &= \frac{1}{\sqrt{3}} (I^{1+1} + I^{01} + I^{11}) \\
  \mathcal{A}^{z-}_{1} &= \mathcal{A}^{1z}_{1} = -\frac{1}{\sqrt{6}} (I^{10} + I^{00} + I^{10}) \\
  \mathcal{A}^{1z}_{1} &= \frac{1}{\sqrt{3}} (I^{1+1} + I^{01} + I^{11}) \\
\end{align*}  
(A2)

For spin state \( Y_2 \):

\begin{align*}
  \mathcal{A}^{z+}_{2} &= \frac{1}{3} (I^{1-1} + I^{10} + I^{00} + I^{11}) \\
  \mathcal{A}^{z-}_{2} &= \mathcal{A}^{1z}_{2} = \frac{1}{3} \sqrt{2} (I^{01} + 2I^{1-1} + I^{00}) \\
  \mathcal{A}^{1z}_{2} &= \frac{1}{3} (I^{1-1} - I^{01} + I^{11}) \\
\end{align*}  
(A3)

For spin state \( Y_3 \):

\begin{align*}
  \mathcal{A}^{z+}_{3} &= \frac{1}{9} (I^{1-1} + I^{00} + I^{11}) \\
  \mathcal{A}^{z-}_{3} &= \mathcal{A}^{1z}_{3} = \frac{1}{9} \sqrt{2} (I^{10} + I^{00} + I^{10}) \\
  \mathcal{A}^{1z}_{3} &= \frac{1}{9} (I^{11} + I^{01} + I^{11}) \\
\end{align*}  
(A4)

For spin state \( Y_4 \):

\begin{align*}
  \mathcal{A}^{z+}_{4} &= \frac{1}{9} \sqrt{5} (I^{1-1} + 3I^{10} - 2I^{00} - 3I^{00} + 7I^{1-1}) \\
  \mathcal{A}^{z-}_{4} &= \mathcal{A}^{1z}_{4} = \frac{1}{9} \sqrt{10} (2I^{10} - 3I^{00} - 4I^{00} - 3I^{00} + 6I^{10} + 2I^{10}) \\
  \mathcal{A}^{1z}_{4} &= \frac{1}{9} \sqrt{5} (I^{11} + 3I^{10} - 2I^{01} - 3I^{00} + 7I^{1-1}) \\
\end{align*}  
(A5)

Appendix B: Wave functions

In this work, we employ the SHO wave functions for \( Y(4630) \) as the input wave functions. For the decay channels of interest, we need a P-wave two-body wave function for the \( Y(4630) \).

For the two-body wave function with quantum numbers \( n_r \) and \( l \) [54]:

\[ \Psi_{\alpha,1,l,1}(k) = -i2 \sqrt{\frac{2}{3}} \pi^{3/4} \sqrt{\frac{11}{15}} \sqrt{\frac{2}{15}} \pi^{1/4} \gamma(m,k) \exp\left(-\frac{R^2k^2}{2}\right) \],  
(B1)

\[ \Psi_{\alpha,2,l,1}(k) = i \frac{2}{\sqrt{3}} \sqrt{\frac{2}{15}} \sqrt{\frac{11}{15}} \gamma(m,k) \exp\left(-\frac{R^2k^2}{2}\right) \],  
(B2)

where \( \gamma(m,k) = \sqrt{\frac{3}{4\pi}} \left(\epsilon_{m} - \epsilon_{0}\right) \cdot k \) is the solid harmonic polynomial, with \( \epsilon_{\pm 1} = (\pm 1/\sqrt{2}, -i/\sqrt{2}, 0) \) and \( \epsilon_{0} = (0, 0, 1) \).
