On the well-posedness in the solution of the disturbance decoupling by dynamic output feedback with self bounded and self hidden subspaces

Fabrizio Padula, and Lorenzo Ntogramatzidis

Abstract

This paper studies the disturbance decoupling problem by dynamic output feedback with required closed-loop stability, in the general case of nonstrictly-proper systems. We will show that the extension of the geometric solution based on the ideas of self boundedness and self hiddenness, which is the one shown to maximize the number of assignable eigenvalues of the closed-loop, presents structural differences with respect to the strictly proper case. The most crucial aspect that emerges in the general case is the issue of the well-posedness of the feedback interconnection, which obviously has no counterpart in the strictly proper case. A fundamental property of the feedback interconnection that has so far remained unnoticed in the literature is investigated in this paper: the well-posedness condition is decoupled from the remaining solvability conditions. An important consequence of this fact is that the well-posedness condition written with respect to the supremal output nulling and infimal input containing subspaces does not need to be modified when we consider the solvability conditions of the problem with internal stability (where one would expect the well-posedness condition to be expressed in terms of supremal stabilizability and infimal detectability subspaces), and also when we consider the solution which uses the dual lattice structures of Basile and Marro.

I. INTRODUCTION

The disturbance decoupling problem (DDP) played a central role in the development of the geometric approach in systems and control theory. Indeed, from the pioneering papers [1], [16], it was recognized that geometry is a natural language for this type of problems; consequently, the solvability conditions of the first disturbance decoupling problems considered in the literature were expressed by means of inclusions involving certain subspaces.

The basic decoupling problem, consisting of the rejection of a disturbance from the output of a system by means of a static state-feedback, was solved in [1] and, independently, in [16], via the introduction of controlled invariant subspaces. These subspaces were then found to be powerful tools in the understanding of many system-theoretic properties of linear time-invariant (LTI)
systems and in the solution of several control problems. The disturbance decoupling problem by static state feedback with the extra requirement of internal stability of the closed-loop was taken into account in [16] with the introduction of stabilizability subspaces. An alternative solution to the same problem was suggested by Basile and Marro in [2], relying on the concept of self bounded controlled invariance, which, unlike the stabilizability subspaces of [16], does not require eigenspace computation; in other words, the solution with self boundedness remains at the fundamental level of finite arithmetics.

A key contribution to the understanding of the advantages deriving from the adoption of self bounded controlled invariant subspaces in the solution of the disturbance decoupling problem by static state-feedback was given in [9], where it was shown that in the solution of this problem there is a number of closed-loop eigenvalues that are fixed for any feedback matrix which solves the decoupling problem; these unassignable eigenvalues are called the fixed poles of the decoupling problem. It is shown in [9] that choosing a particular self bounded subspace, denoted by $\mathcal{V}_n$ in [3], is the best choice in terms of pole assignment, because it ensures that the maximum number of eigenvalues of the closed-loop can be freely assigned.

For systems whose state is not accessible, a state-feedback decoupling filter cannot be implemented. This led to the formulation of the disturbance decoupling problem by dynamic output feedback. The first paper which provided a solution to this problem is [12]. Around the same time, the same problem with the additional requirement of internal stability was addressed in [15] and [8]. In [4], an alternative geometric solution was proposed for this problem which uses self bounded subspaces, as well as their duals, the so-called self hidden subspaces. Again, the importance of this solution lies in the fact that it does not require eigenspace computation. Even more importantly, in [6] it was proved that this solution based on the idea of self boundedness and self hiddenness, is still the best in terms of assignability of the closed-loop dynamics, see also [5] and [7].

Most of the literature in geometric control has been developed for strictly proper systems, i.e., for those systems which have zero feedthrough between the input and the output. For a systematic and well-organized extension of the geometric approach for systems with a possibly non-zero direct feedthrough term we refer to the monograph [14]. The disturbance decoupling problem with dynamic output feedback and nonzero feedthrough has been completely solved in terms of stabilizability and detectability subspaces in [13]. More recently, the approach based on self boundedness and self hiddenness has been generalized in [10] for the disturbance decoupling problem with static state-feedback. In [10], the result of [9] on the fixed poles was also generalized to nonstrictly proper systems.

A significantly more challenging task is the solution of the disturbance decoupling problem by
dynamic output feedback for nonstrictly proper systems using the concepts of self boundedness and self hiddenness. An issue of well-posedness arises in the case where the feedthrough between the control input and the measurement output is non-zero. It was observed in [13] that the solvability conditions, when dealing with the problem in its full generality, need to take into account the well-posedness: this results in a condition that cannot be expressed as the typical subspace inclusion of most control/estimation problems for which a geometric solution is available. In this paper, we study the role that the well-posedness condition plays in the disturbance decoupling problem by dynamic output feedback. We prove, in particular, that this condition is invariant with respect to the stabilizing pair of self bounded and self hidden subspaces involved in the solution of the disturbance decoupling problem. In other words, we show that the well-posedness condition is disjoint, and therefore independent, from the remaining solvability conditions of the decoupling problem. This new property is the key to a full generalization of the solution of the disturbance decoupling problem by dynamic output feedback, as it shows that the fundamental requirement of stability does not reduce the set of well-posed feedback interconnections; therefore, choosing self bounded and self hidden subspaces does not impact on the solvability of the disturbance decoupling problem by dynamic output feedback. Furthermore, it also implies that the solution of [13] can be conveniently re-written with a well-posedness condition for the supremal output nulling and infimal input containing subspaces instead of the corresponding stabilizability and detectability subspaces.

**Notation.** Given a vector space $\mathcal{X}$, we denote by $0_{\mathcal{X}}$ the origin of $\mathcal{X}$. The image and the kernel of matrix $A$ are denoted by $\text{im}A$ and $\ker A$, respectively. When $A$ is square, we denote by $\sigma(A)$ the spectrum of $A$. If $A : \mathcal{X} \rightarrow \mathcal{Y}$ is a linear map and if $\mathcal{J} \subseteq \mathcal{X}$, the restriction of the map $A$ to $\mathcal{J}$ is denoted by $A|\mathcal{J}$. If $\mathcal{X} = \mathcal{Y}$ and $\mathcal{J}$ is $A$-invariant, the eigenstructure of $A$ restricted to $\mathcal{J}$ is denoted by $\sigma(A|\mathcal{J})$. If $\mathcal{J}_1$ and $\mathcal{J}_2$ are $A$-invariant subspaces and $\mathcal{J}_1 \subseteq \mathcal{J}_2$, the mapping induced by $A$ on the quotient space $\mathcal{J}_2/\mathcal{J}_1$ is denoted by $A|\mathcal{J}_2/\mathcal{J}_1$, and its spectrum is denoted by $\sigma(A|\mathcal{J}_2/\mathcal{J}_1)$. Given a map $A : \mathcal{X} \rightarrow \mathcal{X}$ and a subspace $\mathcal{S}$ of $\mathcal{X}$, we denote by $\langle A|\mathcal{S} \rangle$ the smallest $A$-invariant subspace of $\mathcal{X}$ containing $\mathcal{S}$ and by $\langle \mathcal{S}|A \rangle$ the largest $A$-invariant subspace contained in $\mathcal{S}$.

**II. Problem Statements**

In what follows, whether the underlying system evolves in continuous or discrete time makes only minor differences and, accordingly, the time index set of any signal is denoted by $\mathbb{T}$, on the understanding that this represents either $\mathbb{R}^+$ in the continuous time or $\mathbb{N}$ in the discrete time. The symbol $\mathbb{C}_g$ denotes either the open left-half complex plane $\mathbb{C}^-$ in the continuous time or the open unit disc $\mathbb{C}^+$ in the discrete time. A matrix $M \in \mathbb{R}^{n \times n}$ is said to be *asymptotically stable*.
if \( \sigma(M) \subset \mathbb{C}_r \). Finally, we say that \( \lambda \in \mathbb{C} \) is stable if \( \lambda \in \mathbb{C}_g \). The operator \( \mathcal{D} \) denotes either the time derivative in the continuous time, i.e., \( \mathcal{D} x(t) = \dot{x}(t) \), or the unit time shift in the discrete time, i.e., \( \mathcal{D} x(t) = x(t+1) \).

We consider the system \( \Sigma \) governed by

\[
\Sigma : \begin{cases}
\mathcal{D} x(t) = A x(t) + B u(t) + H w(t) \\
y(t) = C x(t) + D_y u(t) + G_y w(t) \\
z(t) = E x(t) + D_z u(t) + G_z w(t),
\end{cases}
\]

where, for all \( t \in \mathbb{T} \), the vector \( x(t) \in \mathcal{X} = \mathbb{R}^n \) denotes the state, \( u(t) \in \mathcal{U} = \mathbb{R}^m \) is the control input, \( w(t) \in \mathcal{W} = \mathbb{R}^q \) is the disturbance input, \( y(t) \in \mathcal{Y} = \mathbb{R}^p \) is the measurement output and \( z(t) \in \mathcal{Z} = \mathbb{R}^r \) is the to-be-controlled output. We consider also the regulator \( \Sigma_c \) ruled by

\[
\Sigma_c : \begin{cases}
\mathcal{D} p(t) = A_c p(t) + B_c y(t) \\
u(t) = C_c p(t) + D_c y(t),
\end{cases}
\]

where, for all \( t \in \mathbb{T} \), the vector \( p(t) \in \mathcal{P} = \mathbb{R}^s \) is the state of the regulator. We want to control the system \( \Sigma \) with the regulator \( \Sigma_c \) such that in the closed-loop system the output \( z \) does not depend on the disturbance input \( w \).

We say that the feedback interconnection of system \( \Sigma \) with the regulator \( \Sigma_c \) is well posed if the matrix \( I - D_y D_c \) is non-singular, see [14, Chpt. 3]. In such case, the closed-loop system \( \Sigma_{cl} \) can be written in state-space form as

\[
\Sigma_{cl} : \begin{cases}
\mathcal{D} \hat{x}(t) = \hat{A} \hat{x}(t) + \hat{H} w(t) \\
z(t) = \hat{C} \hat{x}(t) + \hat{G} w(t),
\end{cases}
\]

where \( \hat{x}(t) = [x(t) \ p(t)] \) is the extended state, and the matrices in (1) are defined by

\[
\hat{A} \overset{\text{def}}{=} \begin{bmatrix} A + BD_c WC & BC_c + BD_c WD_y C_c \\ B_c WC & A_c + B_c WD_y C_c \end{bmatrix}, \quad \hat{H} \overset{\text{def}}{=} \begin{bmatrix} H + BD_c WG_y \\ B_c WG_y \end{bmatrix},
\]

\[
\hat{C} \overset{\text{def}}{=} \begin{bmatrix} E + D_z D_c WC & D_z C_c + D_z D_c WD_y C_c \end{bmatrix}, \quad \hat{G} \overset{\text{def}}{=} G_z + D_z D_c WG_y,
\]

where \( W = (I - D_y D_c)^{-1} \).

The transfer function of the closed-loop system \( \Sigma_{cl} \) is

\[
G_{z,w}(\lambda) = \hat{C} (\lambda I - \hat{A})^{-1} \hat{H} + \hat{G},
\]

where \( \lambda \) represents the \( s \) variable of the Laplace transform in the continuous time or the \( z \) variable of the \( Z \)-transform in the discrete time.

In this paper we are concerned with two problems:
Problem 1: [DDP by Dynamic Output Feedback]
Find a compensator $\Sigma_c$ for $\Sigma$ such that the feedback interconnection of $\Sigma$ with $\Sigma_c$ is well posed and the transfer function matrix $G_{z,w}(\lambda)$ of the closed-loop system $\Sigma_{CL}$ is zero.

Problem 2: [DDP by Dynamic Output Feedback with Stability]
Find a compensator $\Sigma_c$ for $\Sigma$ such that the feedback interconnection of $\Sigma$ with $\Sigma_c$ is well posed, the transfer function matrix $G_{z,w}(\lambda)$ of the closed-loop system $\Sigma_{CL}$ is zero and all the eigenvalues of $\hat{A}$ are in $\mathbb{C}_g$.

III. Geometric Background

Consider a quadruple $(A,B,C,D)$ associated with the non-strictly proper state-space (continuous or discrete-time) system

\[
\begin{cases}
\mathcal{D}x(t) = Ax(t) + Bu(t) \\
y(t) = Cx(t) + Du(t)
\end{cases}
\]

We denote by $\mathcal{R}$ the reachable subspace of the pair $(A,B)$, which is the smallest $A$-invariant subspace containing the column-space of $B$, i.e., $\mathcal{R} = \langle A \mid \text{im}B \rangle$. We denote by $\mathcal{Q}$ the unobservable subspace of the pair $(C,A)$, which is the largest $A$-invariant subspace contained in the null-space of $C$, i.e., $\mathcal{Q} = \langle \text{ker}C \mid A \rangle$. A subspace $\mathcal{V}$ is said to be an $(A,B)$-controlled invariant subspace if, for any initial state $x_0 \in \mathcal{V}$, there exists a control function $u$ such that the state trajectory generated by the system remains identically on $\mathcal{V}$; equivalently, $\mathcal{V}$ is $(A,B)$-controlled invariant if the subspace inclusion $A\mathcal{V} \subseteq \mathcal{V} + \text{im}B$ holds. The control function that maintains the trajectory on $\mathcal{V}$ can always be expressed as a static state feedback $u(t) = Fx(t)$. The condition of $(A,B)$-controlled invariance can be equivalently expressed by saying that there exists a feedback matrix $F$ such that $(A+BF)\mathcal{V} \subseteq \mathcal{V}$. In this case, we say that $F$ is a controlled invariant friend of $\mathcal{V}$. A subspace $\mathcal{V}$ is said to be an $(A,B,C,D)$-output nulling subspace if, for any initial state $x_0 \in \mathcal{V}$, there exists a control function $u$ such that the state trajectory generated by the system
remains in \( \mathcal{V} \) and the output remains identically at zero; equivalently, \( \mathcal{V} \) is \((A,B,C,D)\)-output nulling if the subspace inclusion
\[
\begin{bmatrix}
  A \\
  C 
\end{bmatrix} \mathcal{V} \subseteq (\mathcal{V} \oplus 0_\mathcal{Y}) + \text{im} \begin{bmatrix}
  B \\
  D 
\end{bmatrix}
\]
holds. The control function that maintains the trajectory on \( \mathcal{V} \) can again be expressed as the static state feedback \( u(t) = F x(t) \). The condition of \((A,B,C,D)\)-output nullingness can be equivalently expressed by saying that there exists a feedback matrix \( F \) such that
\[
\begin{bmatrix}
  A + BF \\
  C + DF 
\end{bmatrix} \mathcal{V} \subseteq \mathcal{V} \oplus 0_\mathcal{Y}.
\]
In this case, we say that \( F \) is an output nulling friend of \( \mathcal{V} \). It is easy to see that if \( F \) is an \((A,B,C,D)\)-output nulling friend of \( \mathcal{V} \), we have also the inclusion (in the complexification of \( \mathcal{X} \))
\[(C + DF)(\lambda I - A - BF)^{-1}) \supseteq \mathcal{V}
\]for all \( \lambda \in \mathbb{C} \), see [13]. We denote by \( \mathcal{F}(A,B,C,D)(\mathcal{V}) \) the set of \((A,B,C,D)\)-output nulling friends of \( \mathcal{V} \).

It is easy to see that the set of \((A,B,C,D)\)-output nulling subspaces is closed under addition. Thus, we can define the largest \((A,B,C,D)\)-output nulling subspace \( \mathcal{V}^*_{(A,B,C,D)} \) (also referred to as the weakly unobservable subspace), which is the set of all initial states for which a control function exists that maintains the output identically at zero. The sequence of subspaces \( (\mathcal{V}_i)_{i \in \mathbb{N}} \) given by
\[
\begin{align*}
\mathcal{V}_0 &= \mathcal{X} \\
\mathcal{V}_{i+1} &= \left[ \begin{bmatrix}
  A \\
  C 
\end{bmatrix}\right]^{-1} \left((\mathcal{V}_i \oplus 0_\mathcal{Y}) + \text{im} \begin{bmatrix}
  B \\
  D 
\end{bmatrix}\right)
\end{align*}
\]
is monotonically non-increasing and converges to \( \mathcal{V}^*_{(A,B,C,D)} \) in at most \( n - 1 \) steps, i.e., \( \mathcal{V}_0 \supseteq \mathcal{V}_1 \supseteq \ldots \supseteq \mathcal{V}_h = \mathcal{V}_{h+1} = \ldots \) implies \( \mathcal{V}^*_{(A,B,C,D)} = \mathcal{V}_h \), with \( h \leq n - 1 \).

Given an \((A,B,C,D)\)-output nulling subspace \( \mathcal{V} \), we can define the \((A,B,C,D)\)-reachability subspace \( \mathcal{R}_{\mathcal{V}} \) on \( \mathcal{V} \) as the set of points that can be reached from the origin by means of control functions that maintain the trajectory on \( \mathcal{V} \) and the output at zero. Given an output nulling friend \( F \) of \( \mathcal{V} \), we can determine \( \mathcal{R}_{\mathcal{V}} \) as
\[
\mathcal{R}_{\mathcal{V}} = \langle A + BF \mid \mathcal{V} \cap B \ker D \rangle.
\]
The eigenvalues of \( A + BF \), for \( F \) that varies in \( \mathcal{F}(A,B,C,D)(\mathcal{V}) \), can be divided into two multisets: the eigenvalues of the mapping \( A + BF \mid \mathcal{V} \) and the eigenvalues of \( A + BF \mid \mathcal{Y} \). In turn, the
The eigenvalues of $A + BF | \mathcal{Y}$ can be divided into two multi-sets: the eigenvalues of $A + BF | \mathcal{Y}$ are all freely assignable with a suitable choice of $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$, whereas the eigenvalues of $A + BF | \mathcal{Y}$ are independent from $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$. Likewise, the eigenvalues of $A + BF | \mathcal{Y}$ are all freely assignable with a suitable choice of $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$, whereas the eigenvalues of $A + BF | \mathcal{Y}$ are fixed for all $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$. The fixed poles of $\mathcal{Y}$ can be defined as the unassignable eigenvalues of $A + BF$ with $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$, i.e.,

$$\sigma_{\text{fixed}}(\mathcal{Y}) \doteq \sigma \left( A + BF \left| \frac{\mathcal{Y}}{\mathcal{R}} \right. \right) \cup \sigma \left( A + BF \left| \frac{\mathcal{Y}}{\mathcal{R}} \right. \right), \quad F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y}).$$

It is easy to see that $\sigma_{\text{fixed}}(\mathcal{Y})$ can be alternatively characterized as

$$\sigma_{\text{fixed}}(\mathcal{Y}) = \sigma \left( A + BF \left| \mathcal{R} \right. \right) \cup \sigma \left( A + BF \left| \mathcal{Y} \cap \mathcal{R} \right. \right), \quad F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y}),$$

see [6], [9]. We say that $\mathcal{Y}$ is

- **internally stabilizable** if there exists $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$ such that $\sigma(A + BF | \mathcal{Y}) \subset \mathbb{C}_g$, or, equivalently, if $\sigma(A + BF | \mathcal{Y}) \subset \mathbb{C}_g$;
- **externally stabilizable** if there exists $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$ such that $\sigma(A + BF | \mathcal{Y}) \subset \mathbb{C}_g$, or, equivalently, if $\sigma(A + BF | \mathcal{Y}) \subset \mathbb{C}_g$.

An $(A,B,C,D)$-output nulling subspace that is internally stabilizable is also referred to as an $(A,B,C,D)$-stabilizability output nulling subspace: specifically, an $(A,B,C,D)$-output nulling subspace $\mathcal{Y}$ is an $(A,B,C,D)$-stabilizability output nulling subspace if there exists $F \in \mathcal{F}_{(A,B,C,D)}(\mathcal{Y})$ such that $\sigma(A + BF | \mathcal{Y}) \subset \mathbb{C}_g$. The set of $(A,B,C,D)$-stabilizability output nulling subspaces is closed under addition, and thus it admits a maximum, that we denote by $\mathcal{Y}^*_\varepsilon(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$; this subspace can be interpreted as the set of all initial states for which an input function exists that maintains the output at zero and the state trajectory converges to the origin.

An $(A,B,C,D)$-output nulling subspace $\mathcal{R}$ for which an output nulling friend $F$ exists such that the spectrum of $A + BF | \mathcal{R}$ is arbitrary is called an $(A,B,C,D)$-reachability output nulling subspace. The set of $(A,B,C,D)$-reachability output nulling subspaces is closed under addition, and thus it admits a maximum, that we denote by $\mathcal{R}^*(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$: there holds

$$\mathcal{R}^*(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D}) \subseteq \mathcal{Y}^*_\varepsilon(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D}) \subseteq \mathcal{Y}^*_\varepsilon(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D}).$$

The subspace $\mathcal{R}^*(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$ is also the output nulling reachability subspace on $\mathcal{Y}^*_\varepsilon(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$, i.e., $\mathcal{R}^*(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D}) = \mathcal{R}^*(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$. This subspace can be interpreted as the set of all initial states that are reachable from the origin by control inputs that maintain the output at zero. The spectrum of $A + BF | \mathcal{Y}^*_\varepsilon(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$ is the invariant zero structure of the system, and it is denoted by $Z(\mathcal{A},\mathcal{B},\mathcal{C},\mathcal{D})$.

We say that an $(A,B,C,D)$-output nulling subspace $\mathcal{Y}$ is $(A,B,C,D)$-self bounded if, for any initial state $x_0 \in \mathcal{Y}$, any control that gives an identically zero output is such that the entire
state trajectory is forced to evolve on \( \mathcal{V} \). In terms of subspace inclusions, \( \mathcal{V} \) is \( (A,B,C,D) \)-self bounded if one of the following equivalent conditions holds:

1. \( \mathcal{V} \supseteq \mathcal{V}^{\star}_{(A,B,C,D)} \cap B \ker D; \)
2. \( \mathcal{V} \supseteq \mathcal{R}^{\star}_{(A,B,C,D)}. \)

It follows immediately that \( \mathcal{R}^{\star}_{(A,B,C,D)} \) and \( \mathcal{V}^{\star}_{(A,B,C,D)} \) are \( (A,B,C,D) \)-self bounded subspaces. If \( \mathcal{V}_1 \) and \( \mathcal{V}_2 \) are \( (A,B,C,D) \)-self bounded subspaces and \( \mathcal{V}_1 \subseteq \mathcal{V}_2 \), then every \( (A,B,C,D) \)-output nulling friend of \( \mathcal{V}_2 \) is also an \( (A,B,C,D) \)-output nulling friend of \( \mathcal{V}_1 \), i.e., \( \mathcal{F}_{(A,B,C,D)} \mathcal{V}_2 \subseteq \mathcal{F}_{(A,B,C,D)} \mathcal{V}_1 \). In particular, since \( \mathcal{R}^{\star}_{(A,B,C,D)} \subseteq \mathcal{V}^{\star}_{(A,B,C,D)} \), every \( (A,B,C,D) \)-output nulling friend of \( \mathcal{V}^{\star}_{(A,B,C,D)} \) is also an \( (A,B,C,D) \)-output nulling friend of \( \mathcal{R}^{\star}_{(A,B,C,D)} \).

Moreover, the intersection of \( (A,B,C,D) \)-self bounded subspaces is \( (A,B,C,D) \)-self bounded. Thus, if we define \( \Phi_{(A,B,C,D)} \) to be the set of \( (A,B,C,D) \)-self bounded subspaces, then \( \Phi_{(A,B,C,D)} \) admits both a maximum, which is \( \mathcal{V}^{\star}_{(A,B,C,D)} \), and a minimum, which is \( \mathcal{R}^{\star}_{(A,B,C,D)} \).

Most of the results on conditioned invariance are introduced by duality. We recall that the dual of a quadruple \( (A,B,C,D) \) is the quadruple \( (A^T, C^T, B^T, D^T) \). A subspace \( \mathcal{I} \) is said to be a \( (C,A) \)-conditioned invariant subspace if the subspace inclusion \( A(\mathcal{I} \cap \ker C) \subseteq \mathcal{I} \) holds. The \( (C,A) \)-conditioned invariance condition can be equivalently expressed by saying that there exists an output-injection matrix \( G \) such that \( (A+GC) \mathcal{I} \subseteq \mathcal{I} \). In this case, we say that \( G \) is a conditioned invariant friend of \( \mathcal{I} \). A subspace \( \mathcal{L} \) is \( (C,A) \)-conditioned invariant subspace if and only if \( \mathcal{L}^\perp \) is \( (A^T, C^T) \)-controlled invariant. A subspace \( \mathcal{I} \) is said to be an \( (A,B,C,D) \)-input containing subspace if the subspace inclusion

\[
\begin{bmatrix}
A & B
\end{bmatrix} \left((\mathcal{I} \oplus \mathcal{U}) \cap \ker \begin{bmatrix}
C & D
\end{bmatrix}\right) \subseteq \mathcal{I}
\]

holds. A subspace \( \mathcal{L} \) is \( (A,B,C,D) \)-input containing if and only if \( \mathcal{L}^\perp \) is \( (A^T, C^T, B^T, D^T) \)-output nulling. The condition of input containingness can be equivalently expressed by saying that there exists an output-injection matrix \( G \) such that

\[
\begin{bmatrix}
A+GC \\
B+GD
\end{bmatrix} (\mathcal{I} \oplus \mathcal{U}) \subseteq \mathcal{I}.
\]

In this case, we say that \( G \) is an \( (A,B,C,D) \)-input containing friend of \( \mathcal{I} \). It is easy to see that if \( G \) is an \( (A,B,C,D) \)-input containing friend of \( \mathcal{I} \), we have also

\[
\text{im}\left((\lambda I - A - GC)^{-1}(B + GD)\right) \subseteq \mathcal{I}
\]

for all \( \lambda \in \mathbb{C} \) in the complexification of \( \mathcal{I} \), see [13]. We denote by \( \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \) the set of \( (A,B,C,D) \)-input containing friends of \( \mathcal{I} \). The set of \( (A,B,C,D) \)-input containing subspaces is closed under intersection. Thus, we can define the smallest \( (A,B,C,D) \)-input containing subspace
The sequence of subspaces \( (\mathcal{I}_i)_{i \in \mathbb{N}} \) given by
\[
\begin{cases}
\mathcal{I}_0 = 0_{\mathcal{I}} \\
\mathcal{I}_{i+1} = [A \ B] \left( (\mathcal{I}_i \oplus \mathcal{U}) \cap \ker [C \ D] \right)
\end{cases}
\]
is monotonically non-decreasing and converges to \( \mathcal{I}^*_{(A,B,C,D)} \) in at most \( n-1 \) steps, i.e., \( \mathcal{I}_0 \subset \mathcal{I}_1 \subset \ldots \subset \mathcal{I}_h = \mathcal{I}_{h+1} = \ldots \) implies \( \mathcal{I}^*_{(A,B,C,D)} = \mathcal{I}_h \), with \( h \leq n-1 \). There holds also \( \mathcal{I}^*_{(A,B,C,D)} = \left( \mathcal{V}^*_{(A,C^\top,B^\top,D^\top)} \right)^\perp \).

Given an \((A,B,C,D)\)-input containing subspace \( \mathcal{I} \) and a corresponding \((A,B,C,D)\)-input containing friend \( G \), we define the \((A,B,C,D)\)-detectability subspace associated to it as
\[
\mathcal{D}_G = (\mathcal{I} + C^{-1} \text{im} D | A + GC),
\]
and is the orthogonal complement of the reachability subspace on \( \mathcal{I}^\perp \). The eigenvalues of \( A + GC \), for \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \), can be divided into the eigenvalues of the mapping \( A + GC | \mathcal{I} \) and the eigenvalues of \( A + GC | \mathcal{I}^\perp \). In turn, the eigenvalues of \( A + GC | \mathcal{I} \) can be divided into two multi-sets: the eigenvalues of \( A + GC | (\mathcal{I} \cap \mathcal{D}) \) are fixed, whereas the eigenvalues of \( A + GC | \mathcal{I}^\perp \) all freely assignable with a suitable choice of \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \). Likewise, the eigenvalues of \( A + GC | \mathcal{I}^\perp \) are fixed, while the eigenvalues of \( A + GC | \mathcal{I} \) are freely assignable with a suitable choice of \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \). The fixed poles of \( \mathcal{I} \) are defined as the unassignable eigenvalues of \( A + GC \) with \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \), i.e.,
\[
\sigma_{\text{fixed}}(\mathcal{I}) \overset{\text{def}}{=} \sigma \left( A + GC \middle| \frac{\mathcal{D}_G}{\mathcal{I}} \right) \cup \sigma \left( A + GC \middle| \mathcal{I} \cap \mathcal{D} \right),
\]
or, which is the same, as
\[
\sigma_{\text{fixed}}(\mathcal{I}) = \sigma \left( A + GC \middle| \frac{\mathcal{D}_G}{\mathcal{I}^\perp} \right) \cup \sigma \left( A + GC \middle| \mathcal{I} \cap \mathcal{D} \right), \quad G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}).
\]
We say that the \((A,B,C,D)\)-input containing subspace \( \mathcal{I} \) is

- **internally detectable** if there exists \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \) such that \( \sigma(A + GC | \mathcal{I} \cap \mathcal{D}) \subset \mathbb{C}_g \), or, equivalently, if \( \sigma(A + GC | \mathcal{I} \cap \mathcal{D}) \subset \mathbb{C}_g \);
- **externally detectable** if there exists \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \) such that \( \sigma(A + GC | \mathcal{I}^\perp) \subset \mathbb{C}_g \), or, equivalently, if \( \sigma(A + GC | \mathcal{I}^\perp) \subset \mathbb{C}_g \).

An \((A,B,C,D)\)-input containing subspace that is externally detectable is also referred to as an \((A,B,C,D)\)-detectability input containing subspace: specifically, an \((A,B,C,D)\)-input containing subspace \( \mathcal{I} \) is an \((A,B,C,D)\)-detectability input containing subspace if there exists \( G \in \mathcal{G}_{(A,B,C,D)}(\mathcal{I}) \) such that \( \sigma(A + GC | \mathcal{I}^\perp) \subset \mathbb{C}_g \).

The set of \((A,B,C,D)\)-detectability input containing subspaces admits a minimum, that we denote by \( \mathcal{I}^*_{(A,B,C,D),g} \); there holds \( \mathcal{I}^*_{(A,B,C,D),g} = \left( \mathcal{I}^*_{(A,C^\top,B^\top,D^\top),g} \right)^\perp \).
An input containing subspace $\mathcal{D}$ for which an $(A,B,C,D)$-input containing friend $G$ exists such that the spectrum of $A + GC\bigg|_{\mathcal{D}}$ is arbitrary is called an $(A,B,C,D)$-unobservability input containing subspace. The set of $(A,B,C,D)$-unobservability input containing subspaces is closed under intersection, and thus it admits a minimum, that we denote by $\mathcal{D}^*_{(A,B,C,D)}$; there holds

$$\mathcal{J}^*_{(A,B,C,D)} \subseteq \mathcal{J}^*_{(A,B,C,D)\setminus \mathcal{D}} \subseteq \mathcal{D}^*_{(A,B,C,D)}.$$  

There holds also $\mathcal{D}^*_{(A,B,C,D)} = \mathcal{D}^*_{(A,B,C,D)\setminus \mathcal{D}}$. The spectrum $A + GC\bigg|_{\mathcal{D}}$ coincides with the invariant zero structure of the system, so that $Z_{(A,B,C,D)} = \sigma(A + BF\bigg|_{\mathcal{D}}) = A + GC\bigg|_{\mathcal{D}}$. Finally, we recall that $\mathcal{D}^*_{(A,B,C,D)}$ is the dual of $\mathcal{D}^*_{(A,B,C,D)}$, i.e., $\mathcal{D}^*_{(A,B,C,D)} = (\mathcal{D}^*_{(A,B,C,D)})^\perp$. We say that an $(A,B,C,D)$-input containing subspace $\mathcal{I}$ is $(A,B,C,D)$-self hidden if one of the following equivalent conditions holds:

1) $\mathcal{I} \subseteq \mathcal{J}^*_{(A,B,C,D)} + C^{-1} \text{im} D$;

2) $\mathcal{I} \subseteq \mathcal{D}^*_{(A,B,C,D)}$.

Thus, $\mathcal{D}^*_{(A,B,C,D)}$ and $\mathcal{J}^*_{(A,B,C,D)}$ are $(A,B,C,D)$-self hidden subspaces. If $\mathcal{I}_1$ and $\mathcal{I}_2$ are $(A,B,C,D)$-self hidden subspaces and $\mathcal{I}_1 \subseteq \mathcal{I}_2$, then every $(A,B,C,D)$-input containing friend of $\mathcal{I}_1$ is also an $(A,B,C,D)$-input containing friend of $\mathcal{I}_2$, i.e., $\mathcal{G}_{(A,B,C,D)}(\mathcal{I}_1) \subseteq \mathcal{G}_{(A,B,C,D)}(\mathcal{I}_2)$. In particular,
every \((A,B,C,D)\)-input containing friend of \(\mathcal{S}_{(A,B,C,D)}^*\) is also an \((A,B,C,D)\)-input containing friend of \(\mathcal{D}_{(A,B,C,D)}^*\).

Moreover, the sum of \((A,B,C,D)\)-self hidden subspaces is \((A,B,C,D)\)-self hidden. Thus, if we define \(\Psi_{(A,B,C,D)}\) to be the set of \((A,B,C,D)\)-self hidden subspaces, then \(\Psi_{(A,B,C,D)}\) admits both a maximum, which is \(\mathcal{D}_{(A,B,C,D)}^*\), and a minimum, which is \(\mathcal{S}_{(A,B,C,D)}^*\).

We recall also the two well-known identities

\[
\mathcal{S}_{(A,B,C,D)}^* = \mathcal{V}_{(A,B,C,D)}^* \cap \mathcal{S}_{(A,B,C,D)},
\]

\[
\mathcal{D}_{(A,B,C,D)}^* = \mathcal{V}_{(A,B,C,D)}^* + \mathcal{S}_{(A,B,C,D)}^*.
\]

IV. DUAL LATTICE STRUCTURES

The following results extend the classic results that relate the concepts of output nullingness and input containingness, see [3] Chpt. 5.

**Lemma 1:** Let \(\mathcal{V}\) be an \((A,B,C,D)\)-output nulling subspace and let \(\mathcal{S}\) be an \((A,B,C,D)\)-input containing subspace. Then, \(\mathcal{S} \supseteq B \ker D\) and \(\mathcal{V} \subseteq C^{-1} \im D\).

**Proof:** We have

\[B \ker D = [A \ B] \left( (0_x \oplus \mathcal{W}) \cap \ker [C \ D] \right) \subseteq [A \ B] \left( \mathcal{S} \cap \ker [C \ D] \right) \subseteq \mathcal{S},\]

which proves the first. The second can be proved by duality. 

**Theorem 1:** Let \(\mathcal{V}\) be an \((A,B,C,D)\)-output nulling subspace and let \(\mathcal{S}\) be an \((A,B,C,D)\)-input containing subspace. Then:

- \(\mathcal{V} \cap \mathcal{S}\) is an \((A,B,C,D)\)-output nulling subspace;
- \(\mathcal{V} + \mathcal{S}\) is an \((A,B,C,D)\)-input containing subspace.

**Proof:** We prove the first. Let us consider \(x \in \mathcal{V} \cap \mathcal{S}\). Since \(x \in \mathcal{V}\), there exist \(x_v \in \mathcal{X}\) and \(\omega \in \mathcal{W}\) such that

\[
\begin{bmatrix} A \\ C \end{bmatrix} x = \begin{bmatrix} x_v \\ 0 \end{bmatrix} + \begin{bmatrix} B \\ D \end{bmatrix} \omega
\]

which can be written as the two equations

\[
Ax = x_v + B \omega, \quad (5)
\]

\[
Cx = D \omega. \quad (6)
\]

Since \(x \in \mathcal{S}\), there exist \(x_s \in \mathcal{X}\) and \(u \in \mathcal{W}\) such that

\[
\begin{bmatrix} A \\ B \end{bmatrix} \begin{bmatrix} x \\ u \end{bmatrix} = x_s
\]

and \(Cx + Du = 0\), which can be written as

\[
Ax + Bu = x_s, \quad (7)
\]

\[
Cx + Du = 0. \quad (8)
\]

Subtracting \((5)\) to \((7)\) gives \(x_v - x_s = B(\omega - u)\), and subtracting \((6)\) to \((8)\) gives \(D(\omega - u) = 0\), so that \(x_v - x_s \in B \ker D \subseteq \mathcal{S}\). It follows that \(x_v \in \mathcal{S}\). From \((5)(6)\), it follows that

\[
\begin{bmatrix} A \\ C \end{bmatrix} x \in \mathcal{V} \cap \mathcal{S}.
\]
\((\mathcal{V} \cap \mathcal{S}) \oplus \{0\}_x) + \text{im} \begin{bmatrix} B \\ D \end{bmatrix}\), and since \(x \in \mathcal{V} \cap \mathcal{S}\), the subspace \(\mathcal{V} \cap \mathcal{S}\) is \((A,B,C,D)\)-output nulling. The second can be proved by duality.

We now consider the two quadruples \((A,B,E,D)\) and \((A,[B \ H],E,[D_z \ G_z])\). We denote by \((\mathcal{V}_i)_{i \in \mathbb{N}}\) and \((\mathcal{S}_i)_{i \in \mathbb{N}}\) the two sequences that converge in at most \(n-1\) steps to \(\mathcal{V}_{A,B,E,D}^*\) and \(\mathcal{S}_{A,B,E,D}^*\), respectively. Similarly, we denote by \(\mathcal{I}_{A,B,E,D}^*\) and \(\mathcal{I}_{A,B,E,D}^*\) the corresponding smallest input containing subspaces, and by \((\hat{\mathcal{V}}_i)_{i \in \mathbb{N}}\) and \((\hat{\mathcal{S}}_i)_{i \in \mathbb{N}}\) the two sequences that converge in at most \(n-1\) steps to \(\mathcal{I}_{A,B,E,D}^*\) and \(\mathcal{I}_{A,B,E,D}^*\), respectively. In general, \(\mathcal{V}_{A,B,E,D}^* \subseteq \mathcal{V}_{A,B,E,D}^*\) and \(\mathcal{S}_{A,B,E,D}^* \subseteq \mathcal{S}_{A,B,E,D}^*\); indeed, \(\hat{\mathcal{V}}_i \subseteq \hat{\mathcal{V}}_i\) and \(\hat{\mathcal{S}}_i \subseteq \hat{\mathcal{S}}_i\) for all \(i \in \mathbb{N}\). However, when the inclusion \(\text{im} \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{V}_{A,B,E,D}^* \oplus \{0\}_x) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix}\) holds true, we have \(\hat{\mathcal{V}}_i = \hat{\mathcal{V}}_i\) for all \(i \in \mathbb{N}\). [10, Lemma 3]. Even if we still have \(\hat{\mathcal{V}}_i \subseteq \hat{\mathcal{V}}_i\) for all \(i \in \mathbb{N}\), the identity \(\hat{\mathcal{V}}_i + \hat{\mathcal{S}}_i = \hat{\mathcal{V}}_i + \hat{\mathcal{S}}_i = \hat{\mathcal{V}}_i + \hat{\mathcal{S}}_i\) holds for all \(i,j \in \mathbb{N}\), as the following result shows.

**Lemma 2:** Let \(\text{im} \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{V}_{A,B,E,D}^* \oplus \{0\}_x) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix}\) hold. Then,

\[
\hat{\mathcal{V}}_i + \hat{\mathcal{S}}_j = \hat{\mathcal{V}}_i + \hat{\mathcal{S}}_j
\]

for all \(i,j \in \mathbb{N}\).

**Proof:** We start proving by induction that \(\hat{\mathcal{S}}_j \subseteq \mathcal{V}_{A,B,E,D}^* + \mathcal{S}_j\) for all \(j \in \mathbb{N}\). The statement is trivially true for \(j = 0\). Suppose that \(\hat{\mathcal{S}}_j \subseteq \mathcal{V}_{A,B,E,D}^* + \mathcal{S}_j\) for a certain \(i \in \mathbb{N}\), and we prove that \(\hat{\mathcal{S}}_{i+1} \subseteq \mathcal{V}_{A,B,E,D}^* + \mathcal{S}_{i+1}\). Let \(x \in \hat{\mathcal{S}}_{i+1}\). There exist \(x_1 \in \hat{\mathcal{S}}_i\), \(u \in \mathcal{U}\) and \(w \in \mathcal{W}\) such that \(x = Ax_1 + Bu + Hw\) and \(Ex_1 + D_zu + G_zw = 0\). From \(\text{im} \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{V}_{A,B,E,D}^* \oplus \{0\}_x) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix}\), we can find two matrices \(M\) and \(N\) of suitable sizes such that \(H = VM + BN\) and \(G_z = D_zN\), where \(V\) is a basis matrix of \(\mathcal{V}_{A,B,E,D}^*\). We can rewrite the previous two identities as

\[
x = Ax_1 + Bu + (VM + BN)w
\]

and

\[
Ex_1 + D_zu + (D_zN)w = 0,
\]

i.e.,

\[
x = Ax_1 + B(u + Nw) + VMw
\]

and

\[
Ex_1 + D_z(u + Nw) = 0.
\]

Since \(x_1 \in \hat{\mathcal{S}}_i \subseteq \mathcal{V}_{A,B,E,D}^* + \mathcal{S}_i\), from the inductive assumption, we can write \(x_1 = x_v + x_s\), where \(x_v \in \mathcal{V}_{A,B,E,D}^*\) and \(x_s \in \mathcal{S}_i\), so that

\[
x = Ax_v + Ax_s + B(u + Nw) + VMw
\]

and

\[
Ex_v + Ex_s + D_z(u + Nw) = 0.
\]
Let $F \in \mathfrak{F}_{(A,B,E,D_z)}(V^*_y)$). Adding and subtracting $BF_{x_y}$ in the right hand-side of the first equation and $DF_{x_y}$ in the right hand-side of the second equation gives

$$
\begin{align*}
    x &= A x_y + B(u + N w - F_{x_y}) + (A + BF_{x_y}) x_y + V M w, \\
    0 &= E x_y + D_z(u + N w - F_{x_y}) + (E + D_z F)_{x_y}.
\end{align*}
$$

Clearly, $(A + BF)_{x_y} + V M w \in \mathcal{V}^*_y$ and $(E + D_z F)_{x_y} = 0$. Defining $\omega = u + N w - F_{x_y}$ and $\xi = A x_y + B \omega$, since $E x_y + D_z \omega = 0$ with $x_y \in \mathcal{H}_1$, it follows that $\xi \in \mathcal{H}_1$. Thus, $x \in \mathcal{H}_1 + \mathcal{V}^*_y$ as required. We have proved that $\mathcal{H}_j \subseteq \mathcal{V}^*_y + \mathcal{H}_j$ for all $j \in \mathbb{N}$. Clearly, $\mathcal{V}^*_y + \mathcal{H}_j \subseteq \mathcal{V}^*_y + \mathcal{H}_j$ for all $j \in \mathbb{N}$. Since $\mathcal{V}^*_y = \mathcal{V}^*_y \cap \mathcal{H}_j$, we have $\mathcal{V}^*_y + \mathcal{H}_j \supseteq \mathcal{V}^*_y + \mathcal{H}_j$, $\mathcal{V}^*_y + \mathcal{H}_j \supseteq \mathcal{V}^*_y + \mathcal{H}_j$, and $\mathcal{V}^*_y + \mathcal{H}_j \supseteq \mathcal{V}^*_y + \mathcal{H}_j$ for all $j \in \mathbb{N}$. Finally, since $\mathcal{H}_i \supseteq \mathcal{V}^*_y$ for all $i \in \mathbb{N}$, then $\mathcal{H}_i + \mathcal{H}_j = \mathcal{H}_i + \mathcal{H}_j$ for all $i, j \in \mathbb{N}$.

Following the notation of [3], we denote

$$
\mathcal{V}_m \overset{\text{def}}{=} \mathcal{V}^*_{(A,B,H,E,D_z)} = \mathcal{V}^*_{(A,B,H,E,D_z)} \cap \mathcal{H}_1 = \min \Phi_{(A,B,H,E,D_z)}.
$$

If $\im \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right] \subseteq (\mathcal{V}^*_{(A,B,E,D_z)} + 0_{X}) + \im \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right]$, then we have $\mathcal{V}_m = \mathcal{V}^*_{(A,B,E,D_z)} \cap \mathcal{H}_1$ in view of [9].

We now consider the two quadruples $(A,H,C,G_y)$ and $(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})$. We denote by $(\mathcal{Y}_i)_{i \in \mathbb{N}}$ and $(\mathcal{Y}_i)_{i \in \mathbb{N}}$ the two sequences that converge in at most $n - 1$ steps to $\mathcal{V}^*_{(A,H,C,G_y)}$ and $\mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})}$, respectively. Similarly, we denote by $(\mathcal{A}_i)_{i \in \mathbb{N}}$ and $(\mathcal{A}_i)_{i \in \mathbb{N}}$ the two sequences that converge in at most $n - 1$ steps to $\mathcal{V}^*_{(A,H,C,G_y)}$ and $\mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})}$, respectively. In general, $\mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})} \subseteq \mathcal{V}^*_{(A,H,C,G_y)}$ and $\mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})} \subseteq \mathcal{V}^*_{(A,H,C,G_y)}$. When the inclusion $\ker[ E \ G_z ] \supseteq (\mathcal{V}^* \oplus \mathcal{W}) \cap \ker[ C \ G_y ]$ holds, we have $\mathcal{V}_i = \mathcal{V}_i$ for all $i \in \mathbb{N}$ from the dual of [10] Lemma 3. The following result can be proved by dualizing the proof of Lemma 3.

**Lemma 3:** Let $\ker[ E \ G_z ] \supseteq (\mathcal{V}^*_{(A,H,C,G_y)} \oplus \mathcal{W}) \cap \ker[ C \ G_y ]$. For all $i, j \in \mathbb{N}$ there holds $\mathcal{V}_i \cap \mathcal{V}_j = \mathcal{V}_i \cap \mathcal{V}_j$.

Following the notation of [3], we denote

$$
\mathcal{M} \overset{\text{def}}{=} \mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})} = \mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})} + \max \Phi_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})}.
$$

If $\ker[ E \ G_z ] \supseteq (\mathcal{V}^* \oplus \mathcal{W}) \cap \ker[ C \ G_y ]$, we have $\mathcal{M} = \mathcal{V}^*_{(A,H,\begin{bmatrix} C \\ E \end{bmatrix}, \begin{bmatrix} G_y \\ G_z \end{bmatrix})} + \mathcal{V}^*_{(A,H,C,G_y)}$.

The proof of the following result is straightforward.
**Lemma 4:** The following inclusions hold:

- \( V_{(A,B,E,D_z)}^* \subseteq V_{(A,B,H,E,D_z)}^* \subseteq V_{(A,B,H,E,D_z)}^* \);
- \( \mathcal{S}^*_{(A,H,C,G_z)} \subseteq \mathcal{S}^*_{(A,H,E,D_z)} \subseteq \mathcal{S}^*_{(A,H,E,D_z)} \);
- \( \mathcal{S}^*_{(A,H,C,G_z)} \subseteq \mathcal{S}^*_{(A,H,E,D_z)} \Rightarrow \mathcal{S}^*_{(A,H,E,D_z)} \subseteq \mathcal{S}^*_{(A,H,E,D_z)} \).

**Lemma 5:** Let \( \mathcal{S}^*_{(A,H,C,G_z)} \subseteq \mathcal{S}^*_{(A,H,E,D_z)} \). Then, the subspace \( \mathcal{V}_m + \mathcal{M} \) is \((A, [ B \ H ], E, [ D_z G_z ])\)-self bounded, and the subspace \( \mathcal{V}_m \cap \mathcal{M} \) is \((A, H, [ C E ], [ G_z ])\)-self hidden.

**Proof:** We find

\[
\mathcal{V}_m + \mathcal{M} = (\mathcal{V}^*_{(A,B,H,E,D_z)} \cap \mathcal{S}^*_{(A,B,H,E,D_z)}) + (\mathcal{S}^*_{(A,H,E,D_z)} \cap \mathcal{S}^*_{(A,H,E,D_z)}) + (\mathcal{S}^*_{(A,H,E,D_z)} \cap \mathcal{S}^*_{(A,H,E,D_z)}) + (\mathcal{S}^*_{(A,H,E,D_z)} \cap \mathcal{S}^*_{(A,H,E,D_z)})
\]

in view of the modular rule [14], p. 16] and Lemma [4]. We show that \( \mathcal{V}_m + \mathcal{M} \) is \((A, [ B \ H ], E, [ D_z G_z ])\)-output nulling. The inclusion

\[
\begin{bmatrix}
A \\
C \\
E
\end{bmatrix} \mathcal{V}^*_{(A,H,E,D_z)} \subseteq (\mathcal{V}^*_{(A,H,E,D_z)} + 0_{E}) + \text{im} \begin{bmatrix}
H \\
G_y \\
G_z
\end{bmatrix}
\]

implies

\[
\begin{bmatrix}
A \\
E
\end{bmatrix} \mathcal{V}^*_{(A,H,E,D_z)} \subseteq (\mathcal{V}^*_{(A,H,E,D_z)} + 0_{E}) + \text{im} \begin{bmatrix}
H \\
G_y \\
G_z
\end{bmatrix}
\]

which in turn leads to

\[
\begin{bmatrix}
A \\
E
\end{bmatrix} \mathcal{V}_m \subseteq (\mathcal{V}_m + 0_{E}) + \text{im} \begin{bmatrix}
B \\
D_z \\
G_z
\end{bmatrix}
\]

Adding this to

\[
\begin{bmatrix}
A \\
E
\end{bmatrix} \mathcal{V}^*_{(A,H,E,D_z)} \subseteq (\mathcal{V}^*_{(A,H,E,D_z)} + 0_{E}) + \text{im} \begin{bmatrix}
B \\
D_z \\
G_z
\end{bmatrix}
\]

yields

\[
\begin{bmatrix}
A \\
E
\end{bmatrix} \mathcal{V}_m \subseteq (\mathcal{V}_m + 0_{E}) + \text{im} \begin{bmatrix}
B \\
D_z \\
G_z
\end{bmatrix}
\]

Thus, \( \mathcal{V}_m + \mathcal{M} \) is \((A, [ B \ H ], E, [ D_z G_z ])\)-output nulling. The fact that \( \mathcal{V}_m + \mathcal{V}^*_{(A,H,E,D_z)} \) is self bounded follows immediately from the inclusion \( \mathcal{V}_m + \mathcal{V}^*_{(A,H,E,D_z)} \geq \mathcal{V}_m \supseteq \mathcal{V}^*_{(A,B,H,E,D_z)} \cap [ B \ H ] \text{ker}[ D_z G_z ] \). The second statement follows by duality. ■
**Corollary 1:** Let \( S_{(A,H,C,G_y)}^* \subseteq S_{(A,B,E,D_z)}^* \). The following results hold:

- If \( \text{im} \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right] \subseteq (S_{(A,B,E,D_z)}^* + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \), then \( S_{m} + S_{M} \) is \( (A,B,E,D_z) \)-self bounded.
- If \( \ker \left[ \begin{bmatrix} E \\ G_z \end{bmatrix} \right] \supseteq (S_{(A,H,C,G_y)}^* + S) \cap \ker \left[ \begin{bmatrix} C \\ G_y \end{bmatrix} \right] \), then \( S_{m} + S_{M} \) is \( (A,H,C,G_y) \)-self hidden.

**Proof:** Recall that \( \text{im} \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right] \subseteq (S_{(A,B,E,D_z)}^* + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \) implies \( \text{im} \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right] \subseteq (S_{m} + \mathcal{X}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \) from Theorem 9. Using this inclusion into (10) we obtain

\[
\begin{bmatrix}
A \\
E
\end{bmatrix}
\begin{bmatrix}
S_{m} + S_{(A,H,C,G_y)}^* \\
G_z
\end{bmatrix}
\subseteq \left( (S_{m} + S_{(A,H,C,G_y)}^* + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \right) + \text{im} \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right]
\]

\[
= \left( (S_{m} + S_{(A,H,C,G_y)}^* + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \right) + (S_{m} + 0_{\mathcal{X}})
\]

\[
= \left( (S_{m} + S_{(A,H,C,G_y)}^* + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \right)
\]

We also need to prove that \( S_{m} + S_{M} \supseteq S_{(A,B,E,D_z)}^* \cap B \ker D_z \): this follows from \( S_{m} + S_{M} \supseteq S_{(A,B,E,D_z)}^* \cap \left[ \begin{bmatrix} B \\ H \end{bmatrix} \right] \ker \left[ \begin{bmatrix} D_z \\ G_z \end{bmatrix} \right] \). The second can be proved by duality. \( \blacksquare \)

### V. Problem Solution

We begin by first presenting the following result, see [13] Lemma 3.2. The proof can be carried out along the same lines of the proof of [14] Lemma 5.3. The next few preliminary results involve integers \( n_1, n_2, m, p \in \mathbb{N} \setminus \{0\} \), a field \( \mathbb{F} \), a subspace \( \mathcal{M} \) of \( \mathbb{F}^{n_2} \) and a subspace \( \mathcal{N} \) of \( \mathbb{F}^{n_1} \). We also consider the matrices \( \bar{A} \in \mathbb{F}^{n_1 \times n_2}, \bar{B} \in \mathbb{F}^{n_1 \times m} \) and \( \bar{C} \in \mathbb{F}^{p \times n_2} \).

**Lemma 6:** There holds \( \bar{A} \mathcal{M} \subseteq \mathcal{N} + \text{im} \bar{B} \) and \( \bar{A} (\mathcal{M} \cap \ker \bar{C}) \subseteq \mathcal{N} \) if and only if there exists \( K \in \mathbb{F}^{m \times p} \) such that \( (\bar{A} + \bar{B} \bar{K} \bar{C}) \mathcal{M} \subseteq \mathcal{N} \).

**Lemma 7:** Let \( \mathcal{V} \) be an \( (A,B,E,D_z) \)-output nulling subspace and let \( S \) be an \( (A,H,C,G_y) \)-input containing subspace. If

(a) \( \text{im} \left[ \begin{bmatrix} H \\ G_z \end{bmatrix} \right] \subseteq (\mathcal{V} + 0_{\mathcal{X}}) + \text{im} \left[ \begin{bmatrix} B \\ D_z \end{bmatrix} \right] \),

(b) \( \ker \left[ \begin{bmatrix} E \\ G_z \end{bmatrix} \right] \supseteq (S + \mathcal{W}) \cap \ker \left[ \begin{bmatrix} C \\ G_y \end{bmatrix} \right] \),

(c) \( S \subseteq \mathcal{V} \).

then there exists an output feedback matrix \( K \) such that

\[
\begin{bmatrix}
A + BKC \\
E + D_zKC
\end{bmatrix}
\begin{bmatrix}
H + BKG_y \\
G_z + D_zKG_y
\end{bmatrix}
\left( \mathcal{V} + \mathcal{W} \right) \subseteq \mathcal{V} + 0_{\mathcal{X}}.
\]

(11)
Conversely, if \( K \) exists such that (11) holds, then (a-b) hold.

**Proof:** We prove that if (a-c) hold, then \( K \) exists such that (11) holds. Since \( \mathcal{Y} \) is \((A,B,E,D_z)\)-output nulling, we have \( \begin{bmatrix} A & H \\ E & G_z \end{bmatrix} \mathcal{Y} \subseteq \mathcal{Y} \oplus 0_x + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix} \). Combining this inclusion with (a) yields \( \begin{bmatrix} A & H \\ E & G_z \end{bmatrix} (\mathcal{Y} \oplus \mathcal{W}) \subseteq \mathcal{Y} \oplus 0_x + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix} \). From (c), we also have

\[
\begin{bmatrix} A & H \\ E & G_z \end{bmatrix} (\mathcal{Y} \oplus \mathcal{W}) \subseteq \mathcal{Y} \oplus 0_x + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix}.
\]

Similarly, since \( \mathcal{I} \) is \((A,H,C,G_y)\)-input containing, we have \( \begin{bmatrix} A & H \\ E & G_z \end{bmatrix} (\mathcal{I} \oplus \mathcal{W} \cap \ker \begin{bmatrix} C & G_y \end{bmatrix}) \subseteq \mathcal{I} \). Taking (b) into account gives \( \begin{bmatrix} A & H \\ E & G_z \end{bmatrix} (\mathcal{I} \oplus \mathcal{W} \cap \ker \begin{bmatrix} C & G_y \end{bmatrix}) \subseteq \mathcal{I} \oplus 0_x \). Again, from (c) we obtain

\[
\begin{bmatrix} A & H \\ E & G_z \end{bmatrix} (\mathcal{I} \oplus \mathcal{W} \cap \ker \begin{bmatrix} C & G_y \end{bmatrix}) \subseteq \mathcal{I} \oplus 0_x.
\]

We can now apply Lemma 6 considering the two inclusions (12) and (13), i.e., by considering \( A \rightarrow \begin{bmatrix} A & H \\ E & G_z \end{bmatrix}, B \rightarrow \begin{bmatrix} B \\ D_z \end{bmatrix}, C \rightarrow \begin{bmatrix} C & G_y \end{bmatrix} \), as well as the subspaces \( \mathcal{M} = \mathcal{I} \oplus \mathcal{W} \) and \( \mathcal{N} = \mathcal{Y} \oplus 0_x \).

Thus, there exists \( K \in \mathbb{R}^{p \times m} \) such that

\[
\left( \begin{bmatrix} A & H \\ E & G_z \end{bmatrix} + \begin{bmatrix} B \\ D_z \end{bmatrix} K \begin{bmatrix} C & G_y \end{bmatrix} \right) (\mathcal{I} \oplus \mathcal{W}) \subseteq \mathcal{I} \oplus 0_x,
\]

which is exactly (11). We now prove the converse. Let \( K \) be such that (11) holds. Let \( S \) be a basis matrix of \( \mathcal{I} \) and \( V \) be a basis matrix of \( \mathcal{Y} \). We can re-write (11) as

\[
\begin{bmatrix} A & BK C \\ E + D_z K C & G_z + D_z K G_y \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & I \end{bmatrix} = \begin{bmatrix} V \\ 0 \end{bmatrix} X
\]

for some matrix \( X \) of suitable size, which gives the two equations \( H + B K G_y = V X \) and \( G_z + D_z K G_y = 0 \). These can be rewritten together as \( H G_z = \begin{bmatrix} S \\ 0 \end{bmatrix} X + \begin{bmatrix} 0 \\ V \end{bmatrix} D_z (-K G_y) \), so that (a) holds.

From (14) we also find

\[
\begin{bmatrix} E & G_z \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & I \end{bmatrix} + D_z K \begin{bmatrix} C & D_y \end{bmatrix} \begin{bmatrix} S & 0 \\ 0 & I \end{bmatrix} = 0.
\]

Let \( \begin{bmatrix} y \\ y \end{bmatrix} \in \mathcal{I} \oplus \mathcal{W} \cap \ker \begin{bmatrix} C & D_y \end{bmatrix} \). Then there exists \( \eta \) such that \( \begin{bmatrix} y \\ y \end{bmatrix} = \begin{bmatrix} S \\ 0 \end{bmatrix} \eta \). Multiplying (15) by \( \eta \), since \( \begin{bmatrix} y \\ y \end{bmatrix} \in \ker \begin{bmatrix} C & D_y \end{bmatrix} \), we find \( \begin{bmatrix} E & G_z \end{bmatrix} \begin{bmatrix} y \\ y \end{bmatrix} = 0 \), so that (b) holds.

**Example 5.1:** The existence of a matrix \( K \) satisfying (11) for an \((A,B,E,D_z)\)-output nulling subspace \( \mathcal{Y} \) and an \((A,H,C,G_y)\)-input containing subspace \( \mathcal{I} \) does not imply the condition \( \mathcal{I} \subseteq \mathcal{Y} \). Consider for example

\[
A = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & -1 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} -1 & 0 \\ 1 & 0 \\ 0 & 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 \\ 1 \\ 0 \end{bmatrix},
\]

\[
C = \begin{bmatrix} 1 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad D_y = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad G_y = \begin{bmatrix} -1 \\ 0 \end{bmatrix},
\]

\[
E = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}, \quad D_z = \begin{bmatrix} 0 & 1 \end{bmatrix}, \quad G_z = 1.
\]
with the subspaces \( \mathcal{V} = \text{span}\left\{ \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \\ 0 \end{bmatrix} \right\} \) and \( \mathcal{I} = \text{span}\left\{ \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix} \right\} \). One can easily verify that \( K = \begin{bmatrix} 1 & -1 \\ 1 & -1 \end{bmatrix} \) satisfies (11), and that \( \mathcal{V} \) and \( \mathcal{I} \) are, respectively, \((A,B,E,D_\varepsilon)\)-output nulling and \((A,H,C,G_y)\)-input containing; in addition, \( \mathcal{V} \) satisfies (a) and \( \mathcal{I} \) satisfies (b) of Lemma 7. However, clearly (c) is not satisfied in this case.

The following result contains the generalization of a fundamental property to the case where all the feedthrough matrices are allowed to be nonzero. The major technical difficulty is the fact that in this case, the well-posedness needs to be taken into account. In other words, while showing the feedthrough matrices are allowed to be nonzero. The major technical difficulty is the fact that the conditions of the following theorem are sufficient for the existence of a decoupling filter only requires more convoluted matrix manipulations with respect to the strictly proper case, the necessity needs to be addressed more carefully.

**Theorem 2:** Problem [1] is solvable if and only if there exist an \((A,B,E,D_\varepsilon)\)-output nulling subspace \( \mathcal{V} \), an \((A,H,C,G_y)\)-input containing subspace \( \mathcal{I} \) and a matrix \( K \in \mathbb{R}^{m \times p} \) such that

\[
(i) \ \text{im} \begin{bmatrix} H \\ G_\varepsilon \end{bmatrix} \subseteq (\mathcal{V} \oplus 0_y) + \text{im} \begin{bmatrix} B \\ D_\varepsilon \end{bmatrix};
(ii) \ \ker \begin{bmatrix} E & G_\varepsilon \end{bmatrix} \supseteq (\mathcal{I} \oplus \mathcal{W}) \cap \ker \begin{bmatrix} C & G_y \end{bmatrix};
(iii) \ \mathcal{I} \subseteq \mathcal{V}';
(iv) \ I + KD_y \text{ is non-singular, and } K \text{ satisfies}
\[
\begin{bmatrix}
A + BKC & H + BKG_y \\
E + D_\varepsilon KC & G_\varepsilon + D_\varepsilon K G_y
\end{bmatrix}
(\mathcal{I} \oplus \mathcal{W}) \subseteq \mathcal{V} \oplus 0_y. \tag{16}
\]

**Proof:** (If). We define the compensator matrices as

\[
A_c = A + GC + (B + GD_y) (I + KD_y)^{-1} (F - KC), \\
B_c = (B + GD_y) (I + KD_y)^{-1} K - G, \\
C_c = (I + KD_y)^{-1} (F - KC), \\
D_c = (I + KD_y)^{-1} K.
\]

where \( F \in \mathcal{F}_{(A,B,E,D_\varepsilon)}(\mathcal{V}) \), so that \( \begin{bmatrix} A + BF \\ E + D_\varepsilon F \end{bmatrix} \mathcal{V} \subseteq \mathcal{V} \oplus 0_y \), and where \( G \in \mathcal{G}_{(A,H,C,G_y)}(\mathcal{I}) \), so that \( \begin{bmatrix} A + GC \\ H + G G_y \end{bmatrix} (\mathcal{I} \oplus \mathcal{W}) \subseteq \mathcal{I} \). Using these matrices in (11) and using the matrix inversion lemma\(^1\) after some lengthy but standard matrix manipulations we obtain

\[
\begin{aligned}
\hat{A} &= \begin{bmatrix} A + BKC & B(F - KC) \\
(BK - G)C & A + GC + BF - BKC \end{bmatrix}, \\
\hat{H} &= \begin{bmatrix} H + BKG_y \\
(BK - G)G_y \end{bmatrix}, \\
\hat{C} &= \begin{bmatrix} E + D_\varepsilon KC \\ D_\varepsilon(F - KC) \end{bmatrix}, \\
\hat{G} &= G_\varepsilon + D_\varepsilon K G_y.
\end{aligned}
\]

\(^1\)Given matrices \( P,Q,R,S \) of conformable sizes such that \( P,R \) and \( P+QRS \) are invertible, there holds \( (P + QRS)^{-1} = P^{-1} - P^{-1} Q (R^{-1} + SP^{-1} Q)^{-1} SP^{-1} \).
Defining \( e = x - p \), we obtain
\[
\left[ \begin{array}{c}
\mathcal{D}x(t) \\
\mathcal{D}e(t)
\end{array} \right] = \left[ \begin{array}{cc}
A + BF & B(KC - F) \\
0 & A + GC
\end{array} \right] \left[ \begin{array}{c}
x(t) \\
e(t)
\end{array} \right] + \left[ \begin{array}{c}
H + BKG_y \\
H + GG_y
\end{array} \right] w(t),
\]
\[
z(t) = \left[ E + DzF \quad Dz(KC - F) \right] \left[ \begin{array}{c}
x(t) \\
e(t)
\end{array} \right] + (G_z + DzKG_y) w(t).
\]

We now show that the transfer function \( G_{e,w}(\lambda) \) is zero:
\[
G_{e,w}(\lambda) = \left[ E + DzF \quad Dz(KC - F) \right] \left[ \begin{array}{cc}
\lambda I - A - BF & -B(KC - F) \\
0 & \lambda I - A - GC
\end{array} \right]^{-1} \left[ \begin{array}{c}
H + BKG_y \\
H + GG_y
\end{array} \right] + G_z + DzKG_y
\]
\[
= (E + DzF)(\lambda I - A - BF)^{-1}(H + BKG_y) + (E + DzF)((\lambda I - A - BF)^{-1}(BK - BF)(\lambda I - A - GC)^{-1}(H + GG_y)
\]
\[
+ Dz(KC - F)(\lambda I - A - GC)^{-1}(H + GG_y) + G_z + DzKG_y
\]
\[
= (E + DzF)(\lambda I - A - BF)^{-1}(H + BKG_y) + (E + DzF)((\lambda I - A - BF)^{-1}(BK - BF)(\lambda I - A - GC)^{-1}(H + GG_y)
\]
\[
+ Dz(KC - F)(\lambda I - A - GC)^{-1}(H + GG_y) + G_z + DzKG_y
\]
\[
= (E + DzF)(\lambda I - A - BF)^{-1}(H + BKG_y) + E(\lambda I - A - GC)^{-1}(H + GG_y)
\]
\[
+ Dz(KC - F)(\lambda I - A - GC)^{-1}(H + GG_y) + G_z + DzKG_y
\]
\[
= (E + DzF)(\lambda I - A - BF)^{-1}(H + BKG_y) + (E + DzKC)(\lambda I - A - GC)^{-1}(H + GG_y)
\]
\[
+ Dz(KC - F)(\lambda I - A - GC)^{-1}(H + GG_y) + G_z + DzKG_y,
\]
where we have used the identity \( BK - BF = (\lambda I - A - BF) - (\lambda I - A - BK) \). Now, (16) is equivalent to
\[
(A + BK) \mathcal{S} \subseteq \mathcal{Y},
\]
\[
(E + DzKC) \mathcal{S} = 0, \quad \text{(18)}
\]
\[
\text{im}(H + BKG_y) \subseteq \mathcal{Y}, \quad \text{(19)}
\]
\[
G_z + DzKG_y = 0. \quad \text{(20)}
\]

Eq. (20), together with the inclusion
\[
\ker((E + DzF)(\lambda I - A - BF)^{-1}) \supseteq \mathcal{Y}, \quad \text{(21)}
\]
see (2), yields \( \text{im}(E + D_z F)(\lambda I - A - BF)^{-1}(H + BK G_y) \subseteq (E + D_z F)(\lambda I - A - BF)^{-1} \mathcal{V} = 0_x \), which proves that \( T_1(\lambda) \) is zero. Similarly, (19) with

\[ \text{im}(\lambda I - A - GC)^{-1}(H + GG_y) \subseteq \mathcal{V}, \]

see (4), yields \((E + D_z KC)(\lambda I - A - GC)^{-1}(H + GG_y) \subseteq (E + D_z KC) \mathcal{V} = 0_x \), so that \( T_2(\lambda) \) is zero. From (18) and \( \mathcal{V} \subseteq \mathcal{V} \) we find \( (\lambda I - A - BK C) \mathcal{V} \subseteq \mathcal{V} \). Using this with (22) and (23) gives

\[
(E + D_z F)(\lambda I - A - BF)^{-1}(\lambda I - A - BK C)(\lambda I - A - GC)^{-1}(H + GG_y)
\subseteq (E + D_z F)(\lambda I - A - BF)^{-1}(\lambda I - A - BK C) \mathcal{V} \subseteq (E + D_z F)(\lambda I - A - BF)^{-1} \mathcal{V} = 0_x.
\]

Thus, \( T_3(\lambda) \) is zero. Finally, from (21) we find \( T_4 = G_z + D_z K G_y = 0 \). It follows that \( G_{z,w}(\lambda) = 0 \).

(Only if). Let \( A_c, B_c, C_c \) and \( D_c \) exist such that \( I - D_z D_c \) is non-singular and \( G_{z,w}(\lambda) = 0 \). This implies that \( \hat{G} = 0 \), and there exists an \( \hat{A} \)-invariant subspace \( \hat{\mathcal{V}} \) such that \( \text{im}\hat{H} \subseteq \hat{\mathcal{V}} \subseteq \ker\hat{C} \), see [14] Thm. 4.6. We start proving that \( \mathcal{V} = p(\hat{\mathcal{V}}) \) is \((A, B, E, D_z)\)-output nulling, where \( p \) denotes the projection on \( \hat{\mathcal{V}} \) (see Appendix A). Let \( x \in \mathcal{V} \). There exists \( p \in \mathcal{Y} \) such that \([x]_p \in \hat{\mathcal{V}} \). Since \( \hat{\mathcal{V}} \) is \( \hat{A} \)-invariant, we have \( \hat{A} [x]_p \in \hat{\mathcal{V}} \), i.e.

\[
\begin{bmatrix}
A x + B D_c W C x + B C_c p + B D_c W D_y C_c p \\
B_c W C x + A_c p + B_c W D_y C_c p
\end{bmatrix} \in \hat{\mathcal{V}},
\]

which implies \( A x + B D_c W C x + B C_c p + B D_c W D_y C_c p \in p(\hat{\mathcal{V}}) \). On the other hand, since \( \hat{\mathcal{V}} \subseteq \ker\hat{C} \), we have also \( \hat{C} [x]_p = E x + D_z D_c W C x + D_z C_c p + D_z D_c W D_y C_c p = 0_x \). We can write these two equations together as

\[
\begin{bmatrix}
A \\
E
\end{bmatrix} x + \begin{bmatrix}
B \\
D_z
\end{bmatrix} (D_z W C x + C_c p + D_c W D_y C_c p) \in p(\hat{\mathcal{V}}) + 0_x,
\]

so that \( \begin{bmatrix}
A \\
E
\end{bmatrix} x \in p(\hat{\mathcal{V}}) + 0_x + \text{im} \begin{bmatrix}
B \\
D_z
\end{bmatrix} \). Thus \( \mathcal{V} = p(\hat{\mathcal{V}}) \) is \((A, B, E, D_z)\)-output nulling as required.

Now we prove that \( \mathcal{S} = i(\hat{\mathcal{S}}) \) is \((A, H, C, G_y)\)-input containing, where \( i \) denotes the intersection (see Appendix A). Let \([x]_w \in \mathcal{S} \oplus \mathcal{W} \cap \ker[ C \ G_y ] \). We need to prove that \([A \ H] [x]_w \in \mathcal{S}\). Since \( x \in \mathcal{S} = i(\hat{\mathcal{S}}) \), we obtain \([0]_w \in \hat{\mathcal{S}} \), and since \( \hat{\mathcal{S}} \) is \( \hat{A} \)-invariant, we find \( \hat{A} [x]_w = [Ax + BD_c W C x]_{B_c W C x} \in \hat{\mathcal{S}} \). Since \( \hat{\mathcal{S}} \subseteq \text{im}\hat{H} \), we can write \( \hat{H} w \in \hat{\mathcal{S}} \), i.e., \([H + BD_c W G_y] w \in \hat{\mathcal{S}} \). From the last two relations we find

\[
\begin{bmatrix}
Ax + BD_c W C x + H w + BD_c W G_y w \\
B_c W C x + B_c W G_y w
\end{bmatrix} \in \hat{\mathcal{S}}.
\]

Since \([x]_w \in \ker[ C \ G_y ] \), the latter can be simplified to \([Ax + H w]_0 \in \hat{\mathcal{S}} \), i.e., \([A \ H] [x]_w \in i(\hat{\mathcal{S}}) = \mathcal{S} \), as required.
Now our aim is to show that (i-iii) are satisfied. Since \( \hat{\mathcal{J}} \supseteq \text{im}\hat{H} \), it follows that \( p(\hat{\mathcal{J}}) \supseteq p(\text{im}\hat{H}) \), see Lemma 9 which can be rewritten as \( \mathcal{V} \supseteq \text{im}(H + B D_c W G_y) \). This inclusion together with \( \hat{G} = 0 \) leads to \( \mathcal{V} \supseteq \text{im}(H + B \Phi) \) and \( G_z + D_c \Phi = 0 \), where \( \Phi = D_c W G_y \). Denoting by \( V \) a basis matrix of \( \mathcal{V} \), in view of the these equations there exists a matrix \( X \) such that \( H + B \Phi = VX \) and \( G_z + D_c \Phi = 0 \), i.e., \( \begin{bmatrix} H \\ G_z \end{bmatrix} = \begin{bmatrix} V \\ 0 \end{bmatrix} X + \begin{bmatrix} B \\ D_c \end{bmatrix} \Phi \), so that (i) is satisfied. Since \( \hat{C} \hat{\mathcal{J}} = 0 \) and then \( (E + D_c D_c W C) i(\hat{\mathcal{J}}) = 0 \), see Lemma 9. Since \( \hat{G} = 0 \) then \( (E + \Psi C) \mathcal{J} = 0 \) and \( G_z + \Psi G_y = 0 \). Let \( Q \) be a full row-rank matrix such that \( \text{ker} Q = \mathcal{J} \); we obtain \( \text{ker} Q \subseteq \text{ker}(E + \Psi C) \), so that a matrix \( K \) of suitable size exists such that \( \Theta Q = E + \Psi C \). Thus \( E + \Psi C = \Theta Q \) and \( G_z + \Psi G_y = 0 \), i.e., \( \begin{bmatrix} E & G_z \end{bmatrix} = \Theta \begin{bmatrix} Q & 0 \end{bmatrix} - \Psi \begin{bmatrix} C & G_y \end{bmatrix} \), which another way of writing \( \text{ker} \begin{bmatrix} E & G_z \end{bmatrix} \supseteq \text{ker} \begin{bmatrix} Q & 0 \end{bmatrix} \cap \text{ker} \begin{bmatrix} C & G_y \end{bmatrix} \). Since \( \text{ker} \begin{bmatrix} Q & 0 \end{bmatrix} = \mathcal{J} \oplus \mathcal{W} \), we obtain \( \text{ker} \begin{bmatrix} E & G_z \end{bmatrix} \supseteq (\mathcal{J} \oplus \mathcal{W}) \cap \text{ker} \begin{bmatrix} C & G_y \end{bmatrix} \). We have proved (i-ii). The proof of (iii) follows from \( i(\hat{\mathcal{J}}) \subseteq p(\hat{\mathcal{J}}) \).

From Lemma 7 there exists \( K \in \mathbb{R}^{m \times p} \) such that (11) holds. We show that one of such \( K \) is also such that \( I + KD_y \) is non-singular. Let \( K = D_c W \). From the matrix inversion lemma, \( I + KD_y \) is non-singular. It remains to prove that \( K \) satisfies (11). Rewriting (11) using \( K = D_c W \) gives

\[
\begin{bmatrix}
A + BD_c W C & H + BD_c W G_y \\
E + D_c D_c W C & G_z + D_c W G_y
\end{bmatrix} \quad (\mathcal{J} \oplus \mathcal{W}) \subseteq \mathcal{V} \oplus 0_x.
\]

Let \( \begin{bmatrix} v \\ w \end{bmatrix} \in \mathcal{J} \oplus \mathcal{W} \). We want to prove that

\[
\begin{bmatrix}
A v + BD_c W C v + H w + BD_c W G_y w \\
E v + D_c D_c W C v + G_z w + D_c W G_y w
\end{bmatrix} \in \mathcal{V} \oplus 0_x.
\]

(24)

Since \( v \in \mathcal{J} = i(\hat{\mathcal{J}}) \), we have \( \begin{bmatrix} v \\ 0 \end{bmatrix} \in \hat{\mathcal{J}} \). Since \( \hat{\mathcal{J}} \) is \( \hat{A} \)-invariant, we find \( \begin{bmatrix} v \\ 0 \end{bmatrix} = \begin{bmatrix} A v + BD_c W C v \\ E v + D_c D_c W C v \end{bmatrix} \in \hat{\mathcal{J}} \). It follows that \( A v + BD_c W C v \in p(\hat{\mathcal{J}}) = \mathcal{V} \). Moreover, since \( \text{im}\hat{H} \subseteq \hat{\mathcal{J}} \), we have

\[
\begin{bmatrix} H w + BD_c W G_y w \\
B_c W G_y w
\end{bmatrix} \in \hat{\mathcal{J}}.
\]

In particular, \( H w + BD_c W G_y w \in p(\hat{\mathcal{J}}) = \mathcal{V} \). We have proved that, in (24), there holds \( A v + BD_c W C v + H w + BD_c W G_y w \in p(\hat{\mathcal{J}}) = \mathcal{V} \). Since the system is disturbance decoupled, the feedthrough \( G_z + D_c D_c W G_y \) is zero. Hence, it remains to show that \( E v + D_c D_c W C v = 0 \). This follows from the fact that \( \hat{C} \hat{\mathcal{J}} = 0 \), so that \( \hat{C} \begin{bmatrix} v \\ 0 \end{bmatrix} = 0 \), which gives \( E v + D_c D_c W C v = 0 \).

Remark 1: The statement of Theorem 2 involves conditions that are not independent. Indeed, Lemma 7 showed the relationship between (i-iii) and condition (11) in (iv). Thus, if the necessity and the sufficiency statements are kept separate, some of the conditions in the statement of Theorem 2 are absorbed into the others. However, we prefer this way of presenting this result, because it displays the symmetry between the two implications of the statement.
Remark 2: The well-posedness condition on the invertibility of the matrix $I + KD_y$ is essential in the nonstrictly proper case. Indeed, there are cases where the entire set of all possible $K$ matrices satisfying (11) renders $I + KD_y$ singular. Consider for example

$$
A = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix}, \quad B = \begin{bmatrix} 0 \\ -1 \\ 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 \\ 0 \\ 1 \end{bmatrix}, \quad C = \begin{bmatrix} -1 \\ 0 \\ 1 \end{bmatrix}, \quad D_y = \begin{bmatrix} 1 \\ 0 \\ -1 \end{bmatrix}, \quad G_y = \begin{bmatrix} 0 \\ 0 \\ -1 \end{bmatrix}, \\
E = \begin{bmatrix} 0 & 0 & 1 \end{bmatrix}, \quad D_z = [-1 0], \quad G_z = [0 0], \quad \mathcal{S} = \text{span}\left\{\begin{bmatrix} 1 \\ -1 \end{bmatrix}\right\},
$$

and $\mathcal{V} = \mathbb{R}^3$. Subspace $\mathcal{V}$ is $(A,B,E,D_z)$-output nulling and $\mathcal{S}$ is $(A,H,C,G_y)$-input-input containing, and they satisfy (i-iii) of Theorem 2. Thus, a matrix $K$ exists that satisfies (11). One can easily see that the set of all matrices $K$ for which (11) is fulfilled is given by $K = \begin{bmatrix} -1 & 0 \\ \alpha & \beta \end{bmatrix}$, where $\alpha, \beta$ are free parameters. Clearly, $I + KD_y = \begin{bmatrix} 0 \\ \alpha \\ -\beta \end{bmatrix}$, which is singular for every choice of $\alpha, \beta$.

Remark 3: The if part of the proof of Theorem 2 offers a compensator structure which involves a feedback matrix $K$ such that (11) is satisfied, an $(A,B,E,D_z)$-output-nulling friend $F$ of $\mathcal{V}$ and an $(A,H,C,G_y)$-input containing friend $G$ of $\mathcal{S}$. This, however, does not constitute a parameterization of all the decoupling filters. Consider for example a system described by the matrices

$$
A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}, \quad B = \begin{bmatrix} -1 \\ 0 \end{bmatrix}, \quad H = \begin{bmatrix} 1 \\ 0 \end{bmatrix}, \quad C = [1 0], \\
D_y = G_y = 1, \quad E = [0 -1], \quad D_z = G_z = 0.
$$

One can verify that the compensator described by $A_c = \begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}, \quad B_c = \begin{bmatrix} 0 \\ 10 \end{bmatrix}, \quad C_c = [0 3], \quad D_c = 6$ solves the disturbance decoupling problem. Inverting the last three equations of (17) we obtain

$$
K = D_c (I - D_y D_c)^{-1} = -6/5
$$

$$
F = (I - D_c D_y)^{-1} C_c + KC = \begin{bmatrix} -6/5 & -3/5 \end{bmatrix}
$$

$$
G = (I - D_c D_y)^{-1} (B D_c - B_c) = \begin{bmatrix} 6/5 \\ 2 \end{bmatrix}.
$$

However, when using these values in the first of (17) we obtain $A + GC + (B + GD_y) (I + KD_y)^{-1} (F - KC) = \frac{1}{5} \begin{bmatrix} 11 & 3 \\ 10 & 35 \end{bmatrix}$, which does not coincide with $A_c$. Hence, the decoupling filter proposed here does not fall in the category of those obtainable as in the proof of Theorem 2. Nevertheless, it is still true that a compensator in the desired form can always be found. Indeed,

\footnote{Note also that matrix $G$ is not an input containing friend of $\mathcal{S}$.}
any \((1 \times 1)\) matrix \(K\) satisfies (11). For example, choosing \(K = 1/2\) and the friends \(F = \begin{bmatrix} 1 & 0 \end{bmatrix}\) and \(G = 0\), we obtain

\[
A_{c,1} = A + GC + (B + GD_y)(I + KD_y)^{-1}(F - KC) = \begin{bmatrix} 2/3 & 0 \\ 0 & 1 \end{bmatrix},
\]

\[
B_{c,1} = (B + GD_y)(I + KD_y)^{-1}K - G = -\begin{bmatrix} 1/3 \\ 0 \end{bmatrix},
\]

\[
C_{c,1} = (I + KD_y)^{-1}(F - KC) = \begin{bmatrix} 1/3 \\ 0 \end{bmatrix},
\]

\[
D_{c,1} = (I + KD_y)^{-1}K = 1/3.
\]

In other words, if there exists a compensator that solves the decoupling problem, it may not be obtainable in the way described in the proof of Theorem 2. However, we know that we can always find \(\mathcal{S}\) and \(\mathcal{V}\) as the intersection and projection of an invariant for the extended system contained in \(\ker \hat{C}\) and containing \(\text{im} \hat{H}\) and matrix \(K\), and determining the friends of \(\mathcal{V}\) and \(\mathcal{S}\) we can construct an alternative compensator that may not be the one we had originally. It is now possible to better appreciate the role of condition (iv) in Theorem 2 which guarantees that, even if the parameterization of the decoupling filters is not exhaustive, every controller is associated to at least one feasible matrix \(K\).

The solvability conditions of Theorem 2 can be also stated in terms of \(\mathcal{V}^{*\cap \mathcal{S}}_{(A,B,E,D,\mathcal{G}_y)}\) and \(\mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)}\).

**Corollary 2:** Problem 1 is solvable if and only if there exist a matrix \(K \in \mathbb{R}^{m \times p}\) such that

\[(i) \; \text{im} \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{V}^{*\cap \mathcal{S}}_{(A,B,E,D,\mathcal{G}_y)} \oplus \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)}) \cap \ker \begin{bmatrix} C \\ G_y \end{bmatrix};
\]

\[(ii) \; \ker \begin{bmatrix} E \\ G_z \end{bmatrix} \supseteq (\mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)} \oplus \mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)}) \cap \ker \begin{bmatrix} C \\ G_y \end{bmatrix};
\]

\[(iii) \; \mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)} \subseteq \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)};
\]

\[(iv) \; I + KD_y\text{ is non-singular, and } K\text{ satisfies}
\]

\[
A + BKC & H + BKG_y \\
E + DzKC & Gz + DzKG_y
\]

\[
(\mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)} \oplus \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)}) \subseteq \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)} \oplus \mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)}.
\]

**Proof:** The sufficiency is obvious from Theorem 2. Let us prove the necessity. Let the problem be solvable. In view of Theorem 2, there exist two subspaces \(\mathcal{V}\) and \(\mathcal{S}\) and a matrix \(K\) satisfying all the conditions in its statement. We find

\[
\text{im} \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{V} \oplus 0_x) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix} \subseteq (\mathcal{V}^{*\cap \mathcal{S}}_{(A,B,E,D,\mathcal{G}_y)} \oplus 0_x) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix},
\]

\[
\ker \begin{bmatrix} E \\ G_z \end{bmatrix} \supseteq (\mathcal{S} \oplus \mathcal{V}) \cap \ker \begin{bmatrix} C \\ G_y \end{bmatrix},
\]

\[
(\mathcal{S}_{(A,H,C,G_y)}^{*\cap \mathcal{V}} \subseteq \mathcal{V} \subseteq \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)}; \mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)} \subseteq \mathcal{V} \subseteq \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)};
\]

\[
A + BKC & H + BKG_y \\
E + DzKC & Gz + DzKG_y
\]

\[
(\mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)} \oplus \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)}) \subseteq \mathcal{V}^{*\cap \mathcal{S}}_{(A,H,C,G_y)} \oplus \mathcal{S}^{*\cap \mathcal{V}}_{(A,H,C,G_y)}.
\]
VI. SOLUTION OF PROBLEM 2

We now consider Problem 2. Two necessary solvability conditions are the asymptotic stabilizability of the pair \((A,B)\) and the asymptotic detectability of the pair \((C,A)\) [14, Thm. 3.40]. These are, therefore, standing assumptions for this section. The following result provides a solution to Problem 2 in terms of the largest \((A,B,E,D_z)\)-stabilizability subspace and of the smallest \((A,H,C,G_y)\)-detectability subspace, see [13, Thm. 4.1].

**Theorem 3:** Problem 2 is solvable if and only if there exist a matrix \(K \in \mathbb{R}^{m \times p}\) such that

1. \(\text{im } \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq (\mathcal{Y}^{(A,B,E,D_z)}; \mathcal{W}) \oplus 0_x + \text{im } \begin{bmatrix} B \\ D_z \end{bmatrix} ;\)

2. \(
\begin{bmatrix} E & G_z \end{bmatrix} \left( (\mathcal{S}^{(A,H,C,G_y)}; \mathcal{W}) \cap \ker[ C \ G_y ] \right) = 0_x ;
\)

3. \(\mathcal{S} \subseteq \mathcal{Y} ;\)

4. \(I + K D_y \) is non-singular, and \(K\) satisfies

\[
\begin{bmatrix}
A + BKC & H + BKG_y \\
E + D_z KG_y & G_z + D_z KG_y
\end{bmatrix} (\mathcal{S}^{(A,H,C,G_y)}; \mathcal{W}) \subseteq \mathcal{Y}^{(A,B,E,D_z)}; \mathcal{W} \oplus 0_x .
\]

An immediate consequence is the following result.

**Corollary 3:** Problem 2 is solvable if and only if there exist an \((A,B,E,D_z)\)-stabilizability output nulling subspace \(\mathcal{V}\) and an \((A,H,C,G_y)\)-detectability input containing subspace \(\mathcal{S}\) and a matrix \(K \in \mathbb{R}^{m \times p}\) such that

1. \(\text{im } \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq \mathcal{V} \oplus 0_x + \text{im } \begin{bmatrix} B \\ D_z \end{bmatrix} ;\)

2. \(
\begin{bmatrix} E & G_z \end{bmatrix} \left( (\mathcal{S}; \mathcal{W}) \cap \ker[ C \ G_y ] \right) = 0_x ;
\)

3. \(\mathcal{S} \subseteq \mathcal{V} ;\)

4. \(I + K D_y \) is non-singular, and \(K\) satisfies

\[
\begin{bmatrix}
A + BKC & H + BKG_y \\
E + D_z KG_y & G_z + D_z KG_y
\end{bmatrix} (\mathcal{S}; \mathcal{W}) \subseteq \mathcal{V} \oplus 0_x .
\]

**Proof:** (Only if). It follows directly from Theorem 3 by taking \(\mathcal{V} = \mathcal{Y}^{(A,B,E,D_z)}; \mathcal{W}\) and \(\mathcal{S} = \mathcal{S}^{(A,H,C,G_y)}; \mathcal{W} \).

(If). Since \(\mathcal{V}\) is internally stabilizable, in view of the stabilizability of the pair \((A,B)\), \(\mathcal{V}\) is also externally stabilizable; thus, there exists an output nulling friend \(F\) of \(\mathcal{V}\) such that \(A + BF\) is asymptotically stable. Likewise, since \(\mathcal{S}\) is externally detectable, the detectability of the pair \((C,A)\) ensures that \(\mathcal{S}\) is also internally detectable; it follows that there exists an input containing friend \(G\) of \(\mathcal{S}\) such that \(A + GC\) is asymptotically stable. We can therefore follow the same steps of the proof of Theorem 2 and we obtain that a matrix \(K\) exists such that (26) holds. Defining the compensator matrices in the same way as in the proof of Theorem 2 we obtain
that the eigenvalues of the closed-loop system are $\sigma(A+B F) \cup \sigma(A+G C)$, and $G_{z,w}(\lambda)$ is zero.

We now generalize the solvability stated in terms of self bounded and self hidden subspaces, namely $\mathcal{Y}_m + \mathcal{M}$ in place of $\mathcal{S}_{(A,H,C,G_y)}^\star$ and $\mathcal{Y}_m$ in place of $\mathcal{S}_{(A,B,E,D_z)}^\star$. The first and more important step, which arises in the nonstrictly proper case, is to prove that the well-posedness condition does not change if we choose these self bounded and self hidden subspaces instead of $\mathcal{S}_{(A,H,C,G_y)}^\star$ and $\mathcal{S}_{(A,B,E,D_z)}^\star$.

**Theorem 4:** Let Problem [1] be solvable. The set of matrices $K$ that satisfy (25) coincides with the set of matrices $K$ that satisfy

$$\begin{bmatrix} A+BKC & H+BKG_y \\ E+D_zKG_y & G_z+D_zKG_y \end{bmatrix} (\mathcal{S}_{(A,H,C,G_y)} \oplus \mathcal{Y}) \subseteq \left( \mathcal{S}_{(A,H,C,G_y)} + \mathcal{Y}_m \right) \oplus 0_x. \quad (27)$$

**Proof:** Since $\mathcal{S}_{(A,H,C,G_y)}^\star \subseteq \mathcal{S}_{(A,H,C,G_y)}$ and $\mathcal{S}_{(A,B,E,D_z)}^\star \subseteq \mathcal{S}_{(A,B,E,D_z)}$, if $K$ satisfies (27), it also satisfies (25) since

$$\begin{bmatrix} A+BKC & H+BKG_y \\ E+D_zKG_y & G_z+D_zKG_y \end{bmatrix} (\mathcal{S}_{(A,H,C,G_y)}^\star \oplus \mathcal{Y}) \subseteq \left( \mathcal{S}_{(A,H,C,G_y)}^\star + \mathcal{Y}_m \right) \oplus 0_x \subseteq \mathcal{S}_{(A,B,E,D_z)}^\star \oplus 0_x.$$ 

We now prove that if $K$ satisfies (25), it also satisfies (27). Let $K$ be such that (25) holds. Proving that $K$ also satisfies (27) amounts to proving the four inclusions

$$\begin{align*}
(A+BKC) \mathcal{S}_M & \subseteq \mathcal{S}_M + \mathcal{Y}_m, \quad (28) \\
\operatorname{im}(H+BKG_y) & \subseteq \mathcal{S}_M + \mathcal{Y}_m, \quad (29) \\
(E+D_zKG_y) \mathcal{S}_M &= 0, \quad (30) \\
G_z+D_zKG_z &= 0. \quad (31)
\end{align*}$$

Note that (31) trivially holds because $K$ solves Problem [1] (see proof of Theorem 2). Consider (30). We show that $(E+D_zKG_y) \mathcal{S}_{(A,H,C,G_y)} = 0_x$ implies $(E+D_zKG_y) \mathcal{S}_M = 0_x$. Recall that

$$\mathcal{S}_M = \mathcal{S}_{(A,H,[E],[G_y])}^\star \mathcal{S}_{(A,H,C,G_y)}^\star = \mathcal{S}_{(A,H,C,G_y)}^\star + \mathcal{Y}_{(A,H,[E],[G_y])},$$

where the last equality follows from the fact that Problem [1] is solved. From $(E+D_zKG_y) \mathcal{S}_{(A,H,C,G_y)} = 0_x$, we have

$$(E+D_zKG_y) \mathcal{S}_M = (E+D_zKG_y) \mathcal{S}_{(A,H,C,G_y)}^\star \mathcal{Y}_{(A,H,[E],[G_y])} \subseteq (E+D_zKG_y) \left( \begin{bmatrix} C \\ E \end{bmatrix}^{-1} \operatorname{im} \begin{bmatrix} G_y \\ G_z \end{bmatrix} \right).$$

We prove that

$$(E+D_zKG_y) \left( \begin{bmatrix} C \\ E \end{bmatrix}^{-1} \operatorname{im} \begin{bmatrix} G_y \\ G_z \end{bmatrix} \right) = 0,$$
i.e., 
\[
\left[ C \right]^{-1} \text{im} \left[ G_y \right] \subseteq \ker(E + D_z K G_y).
\]
Let \( x \) be a vector of the left hand-side, so that \( \left[ C \right] x \in \text{im} \left[ G_y \right] \), so that there exists \( w \) such that \( Cx = Gyw \) and \( Ex = Gzw \). Thus,
\[
(E + D_z K G_y) x = Gzw + D_z K Gyw = (G_z + D_z K G_z)w = 0,
\]
as required. Consider (29). We need to prove that \( \text{im}(H + BK G_y) \subseteq \mathcal{V}_{(A,B,E,D_z)}^* \) implies \( \text{im}(H + BK G_y) \subseteq \mathcal{S}_M + \mathcal{V}_m \). Using the last inclusion \( \mathcal{S}_M + \mathcal{V}_m \supseteq \mathcal{V}_{(A,B,E,D_z)}^* \cap \left[ \begin{array}{c} B \\ H \end{array} \right] \ker \left[ \begin{array}{c} D_z \\ G_z \end{array} \right] \) in the proof of Corollary II we only need to prove that \( \text{im}(H + BK G_y) \subseteq \left[ \begin{array}{c} B \\ H \end{array} \right] \ker \left[ \begin{array}{c} D_z \\ G_z \end{array} \right] \). Let \( x \in \text{im}(H + BK G_y) \). There exists \( w \) such that \( x = (H + BK G_y)w \). Let \( g = KGyw \), so that \( x = Hw + Bg \) and from (iv) we also have \( G_z + D_z K G_z = 0 \). Multiplying this by \( w \) gives \( Gzw + D_z g = 0 \). Therefore, \( x = \left[ \begin{array}{c} B \\ H \end{array} \right] \left[ \begin{array}{c} w \\ g \end{array} \right] \), where \( Gzw + D_z g = 0 \). Thus \( x \in \left[ \begin{array}{c} B \\ H \end{array} \right] \ker \left[ \begin{array}{c} D_z \\ G_z \end{array} \right] \) as required. We now prove (28). We have to prove that \( (A + BK C) \mathcal{V}_{(A,H,C,G_y)}^* \subseteq \mathcal{V}_{(A,B,E,D_z)}^* \) implies \( (A + BK C) \mathcal{S}_M \subseteq \mathcal{S}_M + \mathcal{V}_m \). Recall again that, since Problem I is solved,
\[
\mathcal{S}_M = \mathcal{V}_{(A,H,C,G_y)}^* + \mathcal{V}_{(A,H,C,G_y)}^* = \mathcal{V}_{(A,H,C,G_y)}^* + \mathcal{V}_{(A,H,C,G_y)}^* \]
and
\[
\mathcal{S}_M + \mathcal{V}_m \mathcal{V}_m = \mathcal{V}_m + \mathcal{V}_{(A,H,C,G_y)}^* \]
from the proof of Lemma 5. Thus
\[
\mathcal{S}_M + \mathcal{V}_m
\]
\[
= (\mathcal{S}_{(A,B,H,E,D_z,G_z)}^* \cap \mathcal{V}_{(A,B,H,E,D_z,G_z)}^*) + \mathcal{V}_{(A,H,C,G_y)}^* \]
\[
= (\mathcal{S}_{(A,B,H,E,D_z,G_z)}^* \cap \mathcal{V}_{(A,B,H,E,D_z,G_z)}^*) \cap \mathcal{V}_{(A,B,E,D_z)}^* \]
Using these, we need to show that
\[
(A + BK C) \mathcal{V}_{(A,H,C,G_y)}^* \subseteq \mathcal{S}_{(A,B,H,E,D_z,G_z)}^* \cap \mathcal{V}_{(A,B,E,D_z)}^* \]
This reduces to the four inclusions
(a) \( (A + BK C) \mathcal{V}_{(A,H,C,G_y)}^* \subseteq \mathcal{S}_{(A,B,H,E,D_z,G_z)}^* \cap \mathcal{V}_{(A,H,C,G_y)}^* \)
(b) \( (A + BK C) \mathcal{V}_{(A,H,C,G_y)}^* \subseteq \mathcal{V}_{(A,B,E,D_z)}^* \)
(c) \( (A + BK C) \mathcal{S}_{(A,H,C,G_y)}^* \subseteq \mathcal{S}_{(A,B,H,E,D_z,G_z)}^* \cap \mathcal{V}_{(A,B,E,D_z)}^* \)
(d) \( (A + BK C) \mathcal{S}_{(A,H,C,G_y)}^* \subseteq \mathcal{V}_{(A,B,E,D_z)}^* \)

September 18, 2018 DRAFT
Clearly (d) is satisfied because Problem 1 is solvable. We prove (b). The subspace $\mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})}$ satisfies
$$\begin{bmatrix} A \\ C \\ E \end{bmatrix} \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \left( \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \oplus 0_{\mathcal{Y}} \oplus 0_{\mathcal{X}} \right) + \text{im} \begin{bmatrix} H \\ G_y \\ G_z \end{bmatrix}.$$  
Let $\tilde{V}$ be a basis matrix of $\mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})}$, so the latter inclusion ensures in particular the existence of matrices $\Xi$ and $\Theta$ of suitable sizes such that $C \tilde{V} = G_y \Theta$ and $A \tilde{V} = \tilde{V} X + H \Theta$. It follows that $(A + B KC) \tilde{V} = \tilde{V} X + (H + B KG_y) \Theta$, so that
$$(A + B KC) \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} + \text{im}(H + B KG_y).$$

The inclusion $\mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \mathcal{Y}^*_{(A,B,E,D_2)}$, together with $\text{im}(H + B KG_y) \subseteq \mathcal{Y}^*_{(A,B,E,D_2)}$, so that $(A + B KC) \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \mathcal{Y}^*_{(A,B,E,D_2)}$. Now we prove (a). We have already shown that $\text{im}(H + B KG_y) \subseteq [B \ H] \ker[D_z \ G_z]$. Since $\mathcal{S}^*_{(A|B,H,E|D_2,G_z)} \supseteq [B \ H] \ker[D_z \ G_z]$, we have $\text{im}(H + B KG_y) \subseteq \mathcal{S}^*_{(A,B,H,E,D_2,G_z)}$. Adding to both member of this inclusion the subspace $\mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})}$ gives
$$\mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} + \text{im}(H + B KG_y) \subseteq \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} + \mathcal{S}^*_{(A,B,H,E,D_2,G_z)}.$$  
We have also shown that
$$(A + B KC) \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} + \text{im}(H + B KG_y),$$
which readily gives
$$(A + B KC) \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} \subseteq \mathcal{Y}^*_{(A,H,[C,E]^{[G_y]}_{[G_z]})} + \mathcal{S}^*_{(A,B,H,E,D_2,G_z)}.$$  
Finally, we prove (c). We show in particular that
$$(A + B KC) \mathcal{S}^*_{(A,H,C,G_y)} \subseteq \mathcal{S}^*_{(A,B,H,E,D_2,G_z)}, \quad (32)$$

The inclusion (b) can be written as
$$\begin{bmatrix} A^T + C^T K^T B^T \end{bmatrix} \mathcal{S}^*_{(A^T,E^T,B^T,D_2^T)} \subseteq \mathcal{S}^*_{(A^T,[C^T,E^T,H^T,G_y^T,G_z^T])}.$$  
and (33) is equivalent to (32). From (32), it is trivial to see that (b) holds as well.  

**Theorem 5:** Problem 2 is solvable if and only if there exist a matrix $K \in \mathbb{R}^{m \times p}$ such that
$$(A) \ im \begin{bmatrix} H \\ G_z \end{bmatrix} \subseteq \left( \mathcal{Y}^*_{(A,B,E,D_2)} \oplus 0_{\mathcal{Y}} \right) + \text{im} \begin{bmatrix} B \\ D_z \end{bmatrix};$$

3Recall that, if $A \in \mathbb{R}^{m \times n}$, $\mathcal{Y}$ is a subspace of $\mathbb{R}^n$ and $\mathcal{H}$ is a subspace of $\mathbb{R}^m$, then $A \mathcal{Y} \subseteq \mathcal{H}$ is equivalent to $A^T \mathcal{H}^\perp \subseteq \mathcal{Y}^\perp$.

DRAFT
(B) \( \ker[ E \ G_z ] \supseteq \left( (\mathcal{P}^*_{(A,H,C,G_y)} \oplus \mathcal{W}) \cap \ker[ C \ G_y ] \right) \);

(C) \( \mathcal{P}^*_{(A,H,C,G_y)} \subseteq \mathcal{P}^*_{(A,B,E,D_2)} \);

(D) \( \mathcal{P}_m + \mathcal{P}_M \) is an internally stabilizable \((A,B,E,D_2)\)-output nulling subspace;

(E) \( \mathcal{P}_M \) is an externally detectable \((A,H,C,G_y)\)-input containing subspace;

(F) \( I + KD_z \) is non-singular, and \( K \) satisfies

\[
\begin{bmatrix}
A + BKC & H + BKG_y \\
E + DzKG_y & G_z + DzKG_y
\end{bmatrix} \left( \mathcal{P}^*_{(A,H,C,G_y)} \oplus \mathcal{W} \right) \subseteq \mathcal{P}^*_{(A,B,E,D_2)} \oplus 0_x.
\]

\( (34) \)

**Proof:** (If) In view of Corollary 1, the subspace \( \mathcal{P}_m + \mathcal{P}_M \) is \((A,B,E,D_2)\)-output nulling, while \( \mathcal{P}_M \) is obviously \((A,H,C,G_y)\)-input containing. Since, from (D)-(E), \( \mathcal{P}_m + \mathcal{P}_M \) is an internally stabilizable \((A,B,E,D_2)\)-output nulling subspace and \( \mathcal{P}_M \) is an externally detectable \((A,H,C,G_y)\)-input containing subspace, we can chose as \((A,B,E,D_2)\)-stabilizability output nulling subspace the subspace \( \mathcal{P} = \mathcal{P}_m + \mathcal{P}_M \) and as \((A,H,C,G_y)\)-detectability input containing subspace the subspace \( \mathcal{P} = \mathcal{P}_M \). We show that the condition of Corollary 3 are satisfied with this choice of \( \mathcal{P} \) and \( \mathcal{P} \). Condition (iii) is true by construction. Theorem 4 guarantees that condition (iv) is also satisfied. Finally, in view of Lemma 7 the existence of a matrix \( K \) satisfying (iv) implies that also conditions (i) and (ii) hold.

(Only if). We assume that Problem 2 is solvable. In view of Corollary 3, there exist an \((A,B,E,D_2)\)-stabilizability output nulling subspace \( \mathcal{P} \) and an \((A,H,C,G_y)\)-detectability input containing subspace \( \mathcal{P} \) such that conditions (i-iv) in Corollary 3 hold. Since \( \mathcal{P}^*_{(A,H,C,G_y)} \subseteq \mathcal{P} \) (minimality), \( \mathcal{P} \subseteq \mathcal{P}^*_{(A,B,E,D_2)} \) (maximality), and \( \mathcal{P} \subseteq \mathcal{P} \), we find that \((A),(B),(C)\) and \((F)\) are satisfied. Now we prove (D) and (E). To this end, we show that there exists an internally stabilizable \((A,B,E,D_2)\)-self bounded subspace \( \mathcal{P} \) such that \( \mathcal{P}_m \subseteq \mathcal{P} \subseteq \mathcal{P}_m + \mathcal{P}_M \) and an externally detectable \((A,H,C,G_y)\)-self hidden subspace \( \mathcal{P} \) such that \( \mathcal{P}_m \cap \mathcal{P}_M \subseteq \mathcal{P} \subseteq \mathcal{P}_M \). Indeed, consider

\[
\mathcal{P} \overset{\text{def}}{=} \mathcal{P} \cap (\mathcal{P}_m + \mathcal{P}_M) + \mathcal{P}_m = (\mathcal{P} + \mathcal{P}_m) \cap (\mathcal{P}_m + \mathcal{P}_M),
\]

\[
\mathcal{P} \overset{\text{def}}{=} (\mathcal{P} \cap (\mathcal{P}_m + \mathcal{P}_M)) \cap \mathcal{P}_M = (\mathcal{P} \cap \mathcal{P}_M) + (\mathcal{P}_m \cap \mathcal{P}_M).
\]

Since \( \text{im} \left[ H_{G_z} \right] \subseteq (\mathcal{P}^*_{(A,B,E,D_2)} \oplus 0_x) + \text{im} \left[ B_{D_2} \right] \), from Corollary 1 the subspace \( \mathcal{P}_m + \mathcal{P}_M \) is \((A,B,E,D_2)\)-self bounded. Moreover, since \( \ker[ E \ G_z ] \supseteq (\mathcal{P}^*_{(A,H,C,G_y)} \oplus \mathcal{W}) \cap \ker[ C \ G_y ] \), then \( \mathcal{P}_m \cap \mathcal{P}_M \) is \((A,B,C,G_y)\)-self hidden. From [10], Thm. 2], \( \mathcal{P}_m \) is an internally stabilizable \((A,B,E,D_2)\)-output nulling subspace, and, dually, \( \mathcal{P}_M \) is an externally detectable \((A,H,C,G_y)\)-input containing subspace, so that (i) is proved. Since both \( \mathcal{P} \) and \( \mathcal{P}_m \) are \((A,B,E,D_2)\)-output nulling subspaces, so is also their sum \( \mathcal{P} + \mathcal{P}_m \). Moreover, \( \mathcal{P} + \mathcal{P}_m \) is also \((A,B,E,D_2)\)-self bounded; it follows that the intersection \( \mathcal{P} = (\mathcal{P} + \mathcal{P}_m) \cap (\mathcal{P}_m + \mathcal{P}_M) \) is \((A,B,E,D_2)\)-self bounded. Since \( \mathcal{P} + \mathcal{P}_m \) is \((A,B,E,D_2)\)-self bounded and contains \( \mathcal{P} \), which is also \((A,B,E,D_2)\)-self bounded, an output nulling friend \( F \) of \( \mathcal{P} + \mathcal{P}_m \) is also an output nulling friend of \( \mathcal{P} \). Since we can choose \( F \) so that \( \mathcal{P} + \mathcal{P}_m \) is internally stabilized, the same \( F \) stabilizes \( \mathcal{P} \) internally, i.e., \( \mathcal{P} \) is an
internally stabilizable \((A,B,E,D_2)\)-output nulling subspace. Dually, since both \(\mathcal{I}\) and \(\mathcal{I}_M\) are externally detectable \((A,H,C,G_y)\)-input containing subspaces, their intersection \(\mathcal{I} \cap \mathcal{I}_M\) is also externally detectable. Moreover, \(\mathcal{I} \cap \mathcal{I}_M\) is also \((A,H,C,G_y)\)-self hidden; thus, their sum \(\tilde{\mathcal{I}} = (\mathcal{I} \cap \mathcal{I}_M) + (\mathcal{I}_m \cap \mathcal{I}_M)\) is \((A,H,C,G_y)\)-self hidden. Since \(\mathcal{I} \cap \mathcal{I}_M\) is \((A,H,C,G_y)\)-self hidden and contained in \(\tilde{\mathcal{I}}\), which is also \((A,H,C,G_y)\)-self hidden, an input containing friend \(G\) of \(\mathcal{I} \cap \mathcal{I}_M\) is also an input containing friend of \(\tilde{\mathcal{I}}\). Since we can choose \(G\) so that \(\mathcal{I} \cap \mathcal{I}_M\) is externally detected, the same \(G\) renders \(\tilde{\mathcal{I}}\) detected externally, so that \(\tilde{\mathcal{I}}\) is externally detectable.

From Theorem 2, \(\text{im} \left[ \frac{H}{G_z} \right] \subseteq (\mathcal{V}^{*}_{(A,E,D_2)} \oplus 0_x) + \text{im} \left[ \frac{B}{D_2} \right]\) implies \(\text{im} \left[ \frac{H}{G_z} \right] \subseteq (\mathcal{V}_m \oplus 0_x) + \text{im} \left[ \frac{B}{D_2} \right]\), and from its dual ker \([E \quad G_z] \supseteq (\mathcal{I}^{*}_{(A,H,C,G_y)} \oplus \mathcal{W}) \cap \ker [C \quad G_y]\) implies \(\ker [E \quad G_z] \supseteq (\mathcal{I}_M \oplus \mathcal{W}) \cap \ker [C \quad G_y]\). It follows that \(\text{im} \left[ \frac{H}{G_z} \right] \subseteq (\mathcal{V}_m \oplus 0_x) + \text{im} \left[ \frac{B}{D_2} \right] \subseteq (\tilde{\mathcal{V}} \oplus 0_x) + \text{im} \left[ \frac{B}{D_2} \right]\) and \(\ker [E \quad G_z] \supseteq (\mathcal{I}_M \oplus \mathcal{W}) \cap \ker [C \quad G_y]\). Finally, from \(\mathcal{I} \subseteq \mathcal{V}\) we also have the following obvious inclusions

\[
\mathcal{I} \cap \mathcal{I}_M \subseteq \mathcal{I} \subseteq \mathcal{V} \subseteq \mathcal{V} + \mathcal{V}_m,
\]
\[
\mathcal{I} \cap \mathcal{I}_M \subseteq \mathcal{I}_M \subseteq \mathcal{I}_M + \mathcal{V}_m,
\]
which imply that \(\mathcal{I} \cap \mathcal{I}_M\) is contained in the intersection \((\mathcal{V} + \mathcal{V}_m) \cap (\mathcal{I}_M + \mathcal{V}_m) = \tilde{\mathcal{V}}\); likewise

\[
\mathcal{I}_M \cap \mathcal{V}_m \subseteq \mathcal{V}_m \subseteq \mathcal{V} + \mathcal{V}_m\]
\[
\mathcal{I}_M \cap \mathcal{V}_m \subseteq \mathcal{V}_m \subseteq \mathcal{V}_m + \mathcal{I}_M\]

imply that \(\mathcal{I}_M \cap \mathcal{V}_m\) is contained in the intersection \(\tilde{\mathcal{V}} = (\mathcal{V} + \mathcal{V}_m) \cap (\mathcal{I}_M + \mathcal{V}_m)\). Their sum \(\tilde{\mathcal{I}} = (\mathcal{I} \cap \mathcal{I}_M) + (\mathcal{I}_M \cap \mathcal{V}_m)\) is therefore also contained in \(\mathcal{V}\). Thus, \(\tilde{\mathcal{I}} \subseteq \mathcal{V}\).

We already observed that \(\mathcal{I}_M\) is externally detectable. We now prove that \(\mathcal{V}_m + \mathcal{I}_M\) is internally stabilizable. We use the change of coordinate given by a matrix \(T = \begin{bmatrix} T_1 & T_2 & T_3 & T_4 \end{bmatrix}\) such that \(\text{im} T_1 = \mathcal{V}_m \cap \mathcal{I}_M\), \(\text{im} [T_1 \quad T_2] = \mathcal{V}_m\), \(\text{im} [T_1 \quad T_3] = \mathcal{I}_M\), \(\text{im} [T_1 \quad T_2 \quad T_3] = \mathcal{I}_M + \mathcal{V}_m\). We now show that it is always possible to choose \(T_3\) in such a way that \(\text{im} T_3 \subseteq C^{-1} \text{im} G_y\). To this end, we prove that \(\text{im} [T_1 \quad T_3] \supseteq C^{-1} \text{im} G_y + \text{im} T_1\), which means that it is always possible to choose \(T_3\) in such a way that \(\text{im} T_3 \subseteq C^{-1} \text{im} G_y\). We have by definition

\[
\mathcal{I}_M = \mathcal{I}^*(A_H,E,C,G_Y)\]
\[
= \mathcal{V}^*(A_H,E,C,G_Y) + \mathcal{I}^*(A_H,E,C,G_Y)
\]
\[
= \mathcal{V}^*(A_H,E,C,G_Y) + \mathcal{I}^*(A_H,C,G_Y),
\]
where the equality $\mathcal{J}^*_{(A,H,G)} = \mathcal{J}^*_{(A,H,C,G)}$ is a consequence of Theorem 14. In view of Lemma 1, we have $\mathcal{Y}^*_{(A,H,E,G)} \subseteq \mathcal{Y}^*_{(A,H,C,G)} \subseteq \mathcal{Y}^*_{(A,B,H,E,D_G)} \cap \mathcal{J}^*_{(A,H,C,G)}$. We find
\[
\mathcal{Y}_m \cap \mathcal{J}_M = \mathcal{J}^*_{(A,B,H,E,D_G)} \cap (\mathcal{Y}^*_{(A,H,E,G)} \cap \mathcal{J}^*_{(A,H,C,G)}),
\]
where the equality comes from Theorem 1 and since $\mathcal{Y}^*_{(A,H,C,G)} \subseteq \mathcal{Y}^*_{(A,B,H,E,D_G)}$, we find $\mathcal{Y}^*_{(A,H,E,G)} \subseteq \mathcal{Y}^*_{(A,H,C,G)}$. We use this in (35) and obtain
\[
\mathcal{Y}_m \cap \mathcal{J}_M = \mathcal{J}^*_{(A,H,C,G)} \subseteq \mathcal{Y}^*_{(A,B,H,E,D_G)} \cap \mathcal{J}^*_{(A,H,C,G)}.
\]
Consider the other inclusion (together with Theorem 14) $\mathcal{J}^*_{(A,H,C,G)} = \mathcal{Y}^*_{(A,H,E,G)} \subseteq \mathcal{Y}^*_{(A,B,H,E,D_G)} \cap \mathcal{J}^*_{(A,H,C,G)}$. We can use the modular rule on (36) to obtain
\[
\mathcal{Y}_m \cap \mathcal{J}_M = \mathcal{J}^*_{(A,H,C,G)} \subseteq \mathcal{Y}^*_{(A,B,H,E,D_G)} \cap \mathcal{J}^*_{(A,H,C,G)}.
\]
where $\mathcal{J}^*_{(A,B,H,E,D_G)} \cap \mathcal{Y}^*_{(A,H,E,G)} \subseteq C^{-1} \text{im} G_y$. Adding $C^{-1} \text{im} G_y$ to both sides of (37) yields
\[
\text{im} \begin{bmatrix} T_1 & T_3 \end{bmatrix} = \mathcal{J}_M \subseteq C^{-1} \text{im} G_y + \mathcal{J}^*_{(A,H,C,G)},
\]
so that it is always possible to choose $T_3$ in such a way that $\text{im} T_3 \subseteq C^{-1} \text{im} G_y$.

Recall that $\mathcal{Y}_m + \mathcal{J}_M$ is $(A,B,E,D_G)$-output nulling, see Lemma 5, if we denote by $\mathcal{Y}^*_{(A,B,E,D_G)}$ the output nulling reachability subspace on $\mathcal{Y}_m + \mathcal{J}_M$, there holds $(\mathcal{J}_M + \mathcal{Y}_m) \cap B \ker D_z = \mathcal{Y}^*_{(A,B,E,D_G)} \cap B \ker D_z$. Again, since $\mathcal{Y}_m + \mathcal{J}_M$ is $(A,B,E,D_G)$-output nulling, the subspace $\mathcal{Y}^*_{(A,B,E,D_G)}$ is contained in $\mathcal{Y}^*_{(A,B,E,D_G)}$, which in turn is contained in $\mathcal{Y}_m$. Thus, $\text{im} \begin{bmatrix} T_1 & T_2 & T_3 \end{bmatrix} \cap B \ker D_z = \text{im} \begin{bmatrix} T_1 & T_2 & T_3 \end{bmatrix} \cap B \ker D_z$. Then, we can also choose $T_4$ so that $\text{im} \begin{bmatrix} T_1 & T_2 & T_4 \end{bmatrix} \supseteq B \ker D_z$. Let $A_1 = T^{-1} A T$, where $A_1$ is a matrix in $\text{im} H$. Let $A_1 = T^{-1} A T$,
Since \( \mathcal{V}_m \subseteq \mathcal{V} \subseteq \mathcal{S}_M + \mathcal{V}_m \), we can write \( \mathcal{V} = \text{im} \begin{bmatrix} T_1 & T_2 \end{bmatrix} + T_3 X \) for a certain matrix \( X \). In the new basis, we can write
\[
\mathcal{V} = \text{im} \begin{bmatrix} I & 0 & 0 \\ 0 & I & 0 \\ 0 & 0 & X \\ 0 & 0 & 0 \end{bmatrix}.
\]

Since \( \mathcal{V} \) is \((A_1 + B_1 F_1)\) invariant, there exists a matrix \( M \) partitioned conformably such that
\[
\begin{bmatrix}
I & 0 & 0 \\
0 & I & 0 \\
0 & 0 & X \\
0 & 0 & 0
\end{bmatrix} = \begin{bmatrix}
I & 0 & 0 \\
0 & I & 0 \\
0 & 0 & X \\
0 & 0 & 0
\end{bmatrix} \begin{bmatrix}
M_{11} & M_{12} & M_{13} \\
M_{21} & M_{22} & M_{23} \\
M_{31} & M_{32} & M_{33}
\end{bmatrix},
\]
from which we find \( A_{33} X = XM_{33} \). Hence, \( \text{im} X \) is \( A_{3,3} \)-invariant, and since \( \mathcal{V} \) is internally stabilizable, then \( \text{im} X \) is an internally stable \( A_{3,3} \)-invariant.

Similarly, choosing a friend \( G \) of \( \mathcal{V}_m \cap \mathcal{S}_M \) we obtain
\[
A_1 + G_1 C_1 = \begin{bmatrix}
* & * & A_{13} + G_{11} C_{13} & * \\
0 & * & 0 & * \\
0 & * & A_{33} & * \\
0 & * & 0 & *
\end{bmatrix}.
\]

Since \( \mathcal{S}_M \cap \mathcal{V}_m \subseteq \mathcal{S} \subseteq \mathcal{S}_M \), we can write \( \mathcal{S} = \text{im} T_1 + T_3 Y \) for a certain matrix \( Y \). Since \( \mathcal{S} \subseteq \mathcal{V} \), then \( T_3 Y \subseteq T_3 X \); thus \( \text{im} Y \subseteq \text{im} X \). In the new basis, we can write
\[
\mathcal{S} = \text{im} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix}.
\]

From the \((A_1 + G_1 C_1)\)-invariance of \( \mathcal{S} \), there exists a matrix \( N \) partitioned conformably such that
\[
\begin{bmatrix}
* & * & A_{13} + G_{11} C_{13} & * \\
0 & * & 0 & * \\
0 & * & A_{33} & * \\
0 & * & 0 & *
\end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} = \begin{bmatrix} I & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} N_{11} & N_{12} \\ N_{21} & N_{22} \end{bmatrix}.
\]
which yields $A_{33}Y = YN_{22}$. Hence, $\text{im}Y$ is $A_{33}$-invariant, and it is externally stabilizable since $\mathscr{S}$ is externally detectable. Now consider a further change of basis for $A_{33}$ given by $\tilde{T} = [\tilde{T}_1 \ \tilde{T}_2 \ \tilde{T}_3 ]$, where $\tilde{T}_1$ is a basis for $\text{im} Y$, and $[\tilde{T}_1 \ \tilde{T}_2]$ is a basis for $\text{im} X$. Then

$$\tilde{T}^{-1}A_{33}\tilde{T} = \begin{bmatrix} A_{33}^1 & * & * \\ 0 & A_{33}^2 & * \\ 0 & 0 & A_{33}^3 \end{bmatrix}.$$ 

Since $\text{im} X$ is internally stabilizable, $A_{33}^1$ and $A_{33}^2$ are stable; Since $\text{im} Y$ is externally stabilizable, $A_{33}^2$ and $A_{33}^3$ are stable. It follows that $A_{33}$ is stable, so that $\mathscr{S}_M + \mathscr{Y}_m$ is internally stabilizable.

**Concluding Remarks**

In this paper, we have developed a geometric solution to the disturbance decoupling by dynamic output feedback for systems which are not necessarily strictly proper, using the notions of self boundedness and self hiddenness. The building blocks of this solution do not require eigenspace computations that are at the basis of a solution involving stabilizability and detectability subspaces: the solution given here remains in the realm of finite arithmetics. The crucial issue in the extension of the classical theory to the nonstrictly proper case is the well-posedness of the closed-loop, which has to be handled separately from the other solvability conditions. Importantly, in this paper we have showed that checking this condition for the pair of subspaces $\mathscr{Y}_{(A,B,E,D),g}^\star$ and $\mathscr{S}_{(A,H,C,G),g}^\star$, or for the pair of subspaces $\mathscr{Y}_m + \mathscr{S}_M$ and $\mathscr{S}_M$, is equivalent to checking the same condition for the pair of subspaces $\mathscr{Y}_{(A,B,E,D),g}^\star$ and $\mathscr{S}_{(A,H,C,G),g}^\star$.

Appendix A: Projection and Intersection

Consider two vector spaces $\mathcal{X}$ and $\mathcal{P}$. Let $\mathcal{I}$ be a subspace of $\mathcal{X} \oplus \mathcal{P}$. The linear operators $p, i$ are defined as

$$p(\mathcal{I}) \stackrel{\text{def}}{=} \left\{ x \in \mathcal{X} \left| \exists p \in \mathcal{P} : \begin{bmatrix} x \\ p \end{bmatrix} \in \mathcal{I} \right. \right\},$$

$$i(\mathcal{I}) \stackrel{\text{def}}{=} \left\{ x \in \mathcal{X} \left| \begin{bmatrix} x \\ 0 \end{bmatrix} \in \mathcal{I} \right. \right\},$$

where $p(\mathcal{I})$ is referred to as the projection of $\mathcal{I}$ on $\mathcal{X}$ and $i(\mathcal{I})$ is the intersection of $\mathcal{I}$ with $\mathcal{X}$. It is easy to see that $p(\mathcal{I})$ and $i(\mathcal{I})$ are subspaces of $\mathcal{X}$. Both operators preserve addition and intersection, and $p(W) \cap i(W) = (i(W))\perp$, see [3] Prop. 5.1.3.

Lemma 8: Let $W \supseteq \text{im} \begin{bmatrix} H_1 \\ H_2 \end{bmatrix}$. Then, $p(W) \supseteq \text{im} H_1$.

Lemma 9: Let $W \subseteq \ker \begin{bmatrix} C_1 \\ C_2 \end{bmatrix}$. Then, $i(W) \subseteq \ker C_1$.

Appendix B

In this Appendix, we recall some fundamental geometric results for a quadruple $(A,B,C,D)$. These are restatements or dualizations of the results in [6] Appx. A] and [10] Lemma 3], see also [11] Sec. 5. We begin by studying the inclusion $\text{im} L \subseteq \mathcal{V}^{* A,B,C,D}$. The following results hold:

Theorem 6: [10] Lemma 3] Let $\text{im} L \subseteq \mathcal{V}^{* A,B,C,D}$. The following results hold:

i) $\mathcal{V}^{* A,B,C,D} = \mathcal{V}^{* A[ B L ],C[ D 0 ]}$; 

ii) $\Phi_{A[ B L ],C[ D 0 ]} \subseteq \Phi_{A,B,C,D}$; 

iii) $\text{im} L \subseteq \mathcal{V}$ \forall $\mathcal{V} \in \Phi_{A[ B L ],C[ D 0 ]}$.

Theorem 7: [6, Prop. A.1] $\text{im} L \subseteq \mathcal{V}^{* A,B,C,D}$ if and only if $\text{im} L \subseteq \mathcal{R}^{* A[ B L ],C[ D 0 ]}$.
Theorem 8: [6, Prop. A.3] If \( \text{im} L \subseteq \mathcal{Y}_{(A,B,C,D)}^* \), the subspace \( \mathcal{R}^*_{(A,B,L_1,C,D_2)} \) is the smallest of all the \((A,B,C,D)\)-self bounded subspaces \( \mathcal{Y} \) satisfying \( \text{im} L \subseteq \mathcal{Y} \).

The following three results are a generalization of the last three: they are concerned with a geometric condition in the form \( \text{im} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \subseteq \left( \mathcal{Y}_{(A,B,C,D)}^* + 0_\mathcal{Y} \right) + \text{im} \begin{bmatrix} B \\ D \end{bmatrix} \) which arises in the solution of the decoupling of a measurable disturbance.

Theorem 9: Let \( \text{im} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \subseteq \left( \mathcal{Y}_{(A,B,C,D)}^* + 0_\mathcal{Y} \right) + \text{im} \begin{bmatrix} B \\ D \end{bmatrix} \). The following results hold:
- \( \mathcal{Y}_{(A,B,C,D)}^* = \mathcal{Y}_{(A,B,L_1,C,D_2)}^* \);
- \( \Phi_{(A,B,L_1,C,D_2)} \subseteq \Phi_{(A,B,C,D)} \);
- \( \text{im} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \subseteq \mathcal{Y} + 0_\mathcal{Y} + \text{im} \begin{bmatrix} B \\ D \end{bmatrix} \) \( \forall \mathcal{Y} \in \Phi_{(A,B,L_1,C,D_2)} \).

Theorem 10: If \( \text{im} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \subseteq \left( \mathcal{Y}_{(A,B,C,D)}^* + 0_\mathcal{Y} \right) + \text{im} \begin{bmatrix} B \\ D \end{bmatrix} \), the subspace \( \mathcal{R}^*_{(A,B,L_1,C,D_2)} \) is the smallest of all the \((A,B,C,D)\)-self bounded subspaces \( \mathcal{Y} \) satisfying \( \text{im} \begin{bmatrix} L_1 \\ L_2 \end{bmatrix} \subseteq \left( \mathcal{Y} + 0_\mathcal{Y} \right) + \text{im} \begin{bmatrix} B \\ D \end{bmatrix} \).

We now dualize all the previous results. The first three involve an inclusion \( \mathcal{J}_{(A,B,C,D)}^* \subseteq \ker M \), for some matrix \( M \).

Theorem 12: Let \( \mathcal{J}_{(A,B,C,D)}^* \subseteq \ker M \). The following hold:
- \( \mathcal{J}_{(A,B,C,D)}^* = \mathcal{J}_{(A,B,L_1,C,D_2)}^* \);
- \( \Psi_{(A,B,L_1,C,D_2)} \subseteq \Psi_{(A,B,C,D)} \);
- \( \mathcal{J} \subseteq \ker M \) \( \forall \mathcal{J} \in \Psi_{(A,B,L_1,C,D_2)} \).

Theorem 13: \( \mathcal{J}_{(A,B,C,D)}^* \subseteq \ker M \iff \mathcal{J}_{(A,B,L_1,C,D_2)}^* \subseteq \ker M \).

Theorem 14: If \( \mathcal{J}_{(A,B,C,D)}^* \subseteq \ker M \), the subspace \( \mathcal{J}_{(A,B,L_1,C,D_2)}^* \) is the largest of all the \((A,B,C,D)\)-self hidden subspaces \( \mathcal{J} \) satisfying \( \mathcal{J} \subseteq \ker M \).

Finally, we consider the generalization \((\mathcal{J}_{(A,B,C,D)}^* + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \) of the condition \( \mathcal{J}_{(A,B,C,D)}^* \subseteq \ker M \).

Theorem 15: Let \( \mathcal{J}_{(A,B,C,D)}^* + \mathcal{U} \) \( \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \). The following results hold:
- \( \mathcal{J}_{(A,B,C,D)}^* = \mathcal{J}_{(A,B,L_1,C,D_2)}^* \);
- \( \Psi_{(A,B,L_1,C,D_2)} \subseteq \Psi_{(A,B,C,D)} \);
- \( (\mathcal{J} + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \) \( \forall \mathcal{J} \in \Psi_{(A,B,L_1,C,D_2)} \).

Theorem 16: \((\mathcal{J}_{(A,B,C,D)}^* + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \iff (\mathcal{J}_{(A,B,L_1,C,D_2)}^* + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \).

Theorem 17: If \((\mathcal{J}_{(A,B,C,D)}^* + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \), the subspace \( \mathcal{J}_{(A,B,L_1,C,D_2)}^* \) is the largest of all the \((A,B,C,D)\)-self hidden subspaces \( \mathcal{J} \) satisfying \((\mathcal{J} + \mathcal{U}) \cap \ker[ C \ D ] \subseteq \ker[ M_1 \ M_2 ] \).
