Abstract  
Muscarinic acetylcholine receptor (mAChR) activation of pancreatic β-cells elevates intracellular Ca\(^{2+}\) and potentiates glucose-stimulated insulin secretion. In addition, it activates a number of signaling molecules, including ERK1/2, whose activation has been shown to play an important role in regulating pancreatic β-cell function and mass. The aim of this work was to determine how mAChR activation elevates intracellular Ca\(^{2+}\) concentration ([Ca\(^{2+}\)]\(_{i}\)) and activates ERK1/2 in the pancreatic β-cell line MIN6. We demonstrate that agonist-stimulated ERK1/2 activation is dependent on the activation of phospholipase C and an elevation in [Ca\(^{2+}\)]\(_{i}\), but is independent of the activation of diacylglycerol-dependent protein kinase C isoenzymes. Using a pharmacological approach, we provide evidence that agonist-induced increases in [Ca\(^{2+}\)]\(_{i}\) and ERK activity require (1) IP\(_3\) receptor-mediated mobilization of Ca\(^{2+}\) from the endoplasmic reticulum, (2) influx of extracellular Ca\(^{2+}\) through store-operated channels, (3) closure of K\(_{ATP}\) channels, and (4) Ca\(^{2+}\) entry via L-type voltage-operated Ca\(^{2+}\) channels. Moreover, this Ca\(^{2+}\)-dependent activation of ERK is mediated via both Ras-dependent and Ras-independent mechanisms. In summary, this study provides important insights into the multifactorial signaling mechanisms linking mAChR activation to increases in [Ca\(^{2+}\)]\(_{i}\) and ERK activity.

Introduction  
Acetylcholine (ACh) is released by intra-pancreatic vagal nerve endings and activates muscarinic acetylcholine receptors (mAChRs) on pancreatic β-cells during both the pre-absorptive (cephalic phase) and absorptive phases of nutrient intake [1–3]. mAChR activation in the pre-absorptive and absorptive phase potentiates subsequent insulin secretion [1, 2], and these different phases can be modulated independently of each other in both the diabetic and non-diabetic state [4]. Although multiple mAChR subtypes have been reported to be expressed in β-cells (i.e., M\(_1\), M\(_3\), and M\(_4\)) [3, 5–8], selective M\(_3\) mAChR knockout in mice has provided evidence that this receptor subtype is primarily responsible for cholinergic actions in β-cells [3, 9].

The M\(_3\) mAChR preferentially couples to the G\(_{q/11}\)-phospholipase Cβ (PLCβ) signaling pathway. Activation of PLCβ generates inositol 1,4,5-trisphosphate (IP\(_3\)) and diacylglycerol (DAG) through hydrolysis of phosphatidylinositol 4,5-bisphosphate (PIP\(_2\)) [10]. IP\(_3\) activates IP\(_3\) receptors expressed on the endoplasmic reticulum (ER), resulting in the release of Ca\(^{2+}\) from the ER and an increase in cytoplasmic Ca\(^{2+}\) concentration ([Ca\(^{2+}\)]\(_{i}\)). DAG is required for the activation of DAG-dependent kinases, including both conventional and novel isoenzyme subfamilies of PKC.

Stimulation of mAChRs in a variety of excitable and non-excitable cells has been shown to activate multiple signaling pathways, including the extracellular signal-regulated kinases, ERK1/2. For example, in the neuroblastoma cell line SK-N-BE2(C), M\(_3\) mAChR activation stimulates ERK1/2 phosphorylation via a PKCε-, Ras-, Raf- and MEK-dependent mechanism that is independent of [Ca\(^{2+}\)]\(_{i}\) [11, 12]. In contrast, the activation of ERK1/2 by M\(_3\) mAChR activation in human glial cells is dependent on

Ca²⁺ mobilization [13]. In rat islets of Langerhans, carbachol (carbamylcholine, a stable acetylcholine analog) stimulates ERK1/2 phosphorylation [14], and ERK1/2 activation has been reported to stimulate β-cell proliferation and gene transcription, and to influence cell survival and insulin secretion [15–18]. However, the signaling pathway connecting mAChR to ERK1/2 activation in β-cells is poorly understood. Therefore, the principal aim of this study was to determine the signaling mechanism(s) linking the mAChR to ERK1/2 activation in β-cells.

**Materials and methods**

**Chemicals**

Nifedipine and diazoxide were purchased from Calbiochem. All other chemicals (unless stated) were obtained from Sigma.

**Cell culture**

MIN6 cells were used between passages 25 and 40 at ~80% confluence and grown as described previously [19].

**Cell treatments**

Prior to treatment, the medium was removed and cells washed twice with HEPES-balanced Krebs–Ringer bicarbonate (KRB) buffer (115 mM NaCl, 5 mM KCl, 10 mM NaHCO₃, 2.5 mM MgCl₂, 2.5 mM CaCl₂, 20 mM HEPES, pH 7.4). The cells were then incubated for 1 h at 37°C in KRB buffer prior to treatments for the times indicated in the figure legends. All inhibitors were added 30 min prior to treatments. All treatments were stopped by the addition of ice-cold lysis buffer (1% Triton-X100, 10 mM β-glycerophosphate, 50 mM Tris–HCl, pH 7.5, 1 mM EDTA, 1 mM EGTA, 1 mM sodium orthovanadate, 1 mM benzamidine HCl, 0.2 mM phenylmethylsulfonyl fluoride, 1 μg/mL each of leupeptin and pepstatin, 0.1% β-mercaptoethanol, and 50 mM sodium fluoride). The lysates were then centrifuged at 4°C for 10 min at 16,000 x g, supernatants kept, and total protein concentrations determined by the Bradford assay (Bio-Rad). The protein lysates were stored at −80°C until further analysis.

**Plasmid DNA constructs and transfections**

Transfections of MIN6 cells were carried out only for single-cell imaging studies. The DIER cameleon- [20], eGFP-PHPLCδ1- [21], and GFP-PKCε-containing plasmids were provided by Prof. Roger Tsien (University of California, USA), Prof. Stephen Ferguson (Roberts Research Institute, University of Ontario, Canada) and Prof. Tobias Meyer (Stanford University, USA), respectively. DNA was transfected using LipofectAMINE2000 (Invitrogen) according to the manufacturer’s instructions. Transfection efficiency was approximately 10–20% as determined by GFP expression.

**Adenoviral constructs and infection**

AdRasN17 was a gift from Prof. B. Kahn and Dr. C. Sutherland [22]. AdEmpty.eGFP has been described previously [23]. MIN6 cells were infected with the viruses for 48 h as previously described [23] prior to performing the experiments. We routinely obtained 90–100% transduction efficiency as assessed by GFP expression.

**SDS–polyacrylamide gel electrophoresis (PAGE) and immunoblotting**

SDS-PAGE and Western blotting were performed as previously described [24]. Rabbit anti-phospho-ERK1/2 and anti-ERK2 antibodies were purchased from Cell Signaling Technology. Detection was by horseradish peroxidase-linked anti-rabbit secondary antibodies and enhanced chemiluminescence (Cheshire Biosciences).

**Single-cell confocal Ca²⁺ imaging**

For Ca²⁺ imaging, MIN6 cells were loaded for 30 min at 20°C with 2 µM of Fluo-4-AM prepared in dye loading buffer (KRB supplemented with 1 mg/mL BSA and 0.1% Pluronic F-127). The cells were then washed in KRB and incubated for a further 10 min in KRB to allow de-esterification of the indicator. Measurement of changes in fluorescence, as an indicator of [Ca²⁺]i, was observed using a PerkinElmer UltraVIEW confocal microscope. Fluo-4 was excited using the 488-nm laser-line and 485-nm excitation filter, and the emitted fluorescence was captured at wavelengths >520 nm, with images collected at approximately 2-s intervals. Raw fluorescence data were expressed as F/F₀. Data are reported as the mean SEM from at least three individual experiments.

**Population NOVOstar Ca²⁺ imaging**

Population-based Ca²⁺ fluorescence measurements were taken using a NOVOstar microplate reader (BMG LabTechnologies, Offenburg, Germany). MIN6 cells were grown on a 96-well plate format, were washed twice with KRB buffer and then loaded and equilibrated with 2 µM Fluo-4-AM as described previously. Cells were excited at
488 nm, with emission recorded at 520 nm every 0.5 s. Raw fluorescence data were expressed as $F/F_0$ (stimulated fluorescence/basal fluorescence). Data are reported as the average SEM from at least three individual experiments.

**Measurement of [3H]IP$_x$**

For the determination of [3H]-labeled inositol mono-, bis-, and trisphosphates ([3H]IP$_x$), MIN6 cells were pre-labeled with 2.5 Ci/mL myo-[3H]inositol (86 Ci/mmol) for 48 h in 24-well multidishes. Medium was then removed, and the cell monolayers washed and incubated for 30 min in 1 mL of KRB in the absence or presence of 10 mM LiCl (see "Results" section). Carbachol was added as indicated and incubations terminated by rapid aspiration and addition of ice-cold 0.5 M trichloroacetic acid. Samples were neutralized as described previously and the neutral extract applied to Dowex (AG1-X8) formate columns, which was then washed with 20 mL of water and 10 mL of 25 mM ammonium formate. The [3H]IP$_x$ fraction was eluted with 10 mL of 1 M ammonium formate/0.1 M formic acid and quantified by liquid scintillation spectrometry.

**Measurement of [3H]phosphoinositides**

[3H]Glycerophosphoinositol phosphates (GroPI, GroPI(4)P and GroPI(4,5)P$_2$), as indices of PI, PI(4)P, and PI(4,5)P$_2$, were prepared from cell monolayers based on previously described methods [25]. After removal of the acidified aqueous phase for the determination of [3H]IP$_x$ as described above, lipids were extracted into 0.94 mL of acidified chloroform/methanol (40:80:1 v/v, 10 M HCl). Chloroform (0.31 mL) and 0.1 M HCl (0.56 mL) were then added to induce phase partition. A sample of the lower phase (450 μL) was removed and dried in a stream of N$_2$. Dried samples were dissolved in 1 mL of chloroform and 0.2 mL of methanol and hydrolyzed by the addition of 0.4 mL of 0.5 M NaOH in methanol/water (19:1, v/v). Samples were vortex-mixed at regular intervals during a 20-min incubation at 25°C. Chloroform (1 mL), methanol (0.6 mL), and water (0.6 mL) were then added, and the samples were mixed and centrifuged (3,000 × g, 10 min). A 1-mL aliquot of the upper phase was neutralized using 1-mL bed volume of Dowex-50 (H$^+$ form) columns that were washed with 2 × 2 mL of water. The pooled eluate was brought to pH 7 by the addition of NaHCO$_3$ and applied to a Dowex (AG1-X8) formate anion exchange column. The [3H]Gro-PI, [3H]GroPI(4)P, and [3H]GroPI(4, 5)P$_2$ were then eluted as described elsewhere [25] and quantified by liquid scintillation spectrometry.

**Statistical analysis**

Statistical differences between multiple groups were analyzed via either single-factor or two-way analysis of variance (ANOVA), followed by post hoc analysis as described in figure legends. A statistical test was only carried out when the experiments have at least $n = 3$. Statistical analyses were performed in GraphPad Prism, and significance was only confirmed when $P < 0.05$ (*$P < 0.05$; **$P < 0.01$; ***$P < 0.001$).

**Results**

Characterization of carbachol-stimulated ERK1/2 phosphorylation in the pancreatic β-cell line MIN6

Carbachol addition caused a rapid, transient increase in the phosphorylation of ERK1/2 (peaking at 2 min and rapidly returning to basal levels within 10 min; Fig. 1a). The carbachol-stimulated phosphorylation of ERK1/2 at 2 min was concentration dependent, yielding an EC$_{50}$ value of approx. 7 μM (Fig. 1b). Carbachol addition also stimulated a rapid, concentration-dependent increase in [Ca$^{2+}$], (EC$_{50}$ value approx. 0.9 μM) (Fig. 1c). To confirm that carbachol
was mediating these actions via mAChR activation, MIN6 cells were treated with carbachol, or the mAChR-selective agonist methacholine, in the absence and presence of the mAChR antagonist atropine. Both the carbachol- and methacholine-stimulated phosphorylations of ERK1/2 were completely inhibited in the presence of atropine (Fig. 1d).

To examine the role of PLC in carbachol-stimulated ERK1/2 phosphorylation, MIN6 cells were treated with carbachol at the concentrations indicated for 2 min. Proteins were separated by SDS–PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. Data shown in lower panel are means SEM (n = 3); ns no significance, ***P < 0.001 by Dunnett’s range test following one-way ANOVA comparing to no carbachol addition. e MIN6 cells were pre-treated with U73122 (1 μM) for 30 min prior to treatment with carbachol (1 mM, 2 min). Proteins were separated by SDS–PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. Lower panel are means SEM (n = 3). Data were analyzed by a Student’s 2-tailed t test; ***P < 0.001. All immunoblots shown are representative of three independent experiments.

Carbachol-stimulated ERK1/2 activation is MEK dependent and occurs via both Ras-dependent and Ras-independent mechanisms.
recombinant adenovirus expressing dominant-negative Ras (RasN17), and 48 h post-infection, cells were treated with carbachol, EGF (which activate ERK1/2 in a Ras-dependent manner) or GLP1 (which activates ERK1/2 in a Ras-independent manner) [23]. As expected, RasN17 completely inhibited EGF-stimulated ERK1/2 phosphorylation and was without effect on the GLP1-stimulated response (Fig. 2a). mAChR-mediated phosphorylation of ERK1/2 was only partially inhibited, indicating that carbachol can activate ERK1/2 by both Ras-dependent and Ras-independent mechanisms (Fig. 2a). To determine whether carbachol-stimulated ERK1/2 phosphorylation is mediated by MEK, MIN6 cells were treated with carbachol in the absence or presence of two structurally distinct MEK inhibitors, PD184352 and U0126. Either inhibitor completely abolished carbachol-stimulated ERK1/2 phosphorylation (Fig. 2b).

Carbachol-stimulated ERK1/2 phosphorylation is independent of the activation of both conventional and novel isoenzymes of PKC.

Activation of PLCβ by the M₃ mAChR results in the hydrolysis of PIP₂ to generate IP₃ and DAG [10, 26]. DAG is required for the activation of DAG-dependent kinases, including conventional and novel PKC isoenzymes [27], which have been implicated in mAChR activation of ERK1/2 [11, 12]. To confirm that carbachol activates the PLC-DAG-PKC pathway in β-cells, MIN6 cells were transfected with GFP-tagged PKCε (GFP-PKCε). Translocation of this biosensor to the plasma membrane is indicative of an increase in the concentration of DAG and the activation of PKC. Both carbachol (Fig. 3a) and 12-o-tetradecanoylphorbol-13-acetate (TPA, a DAG-mimetic, used as a positive control; Fig. 3b) treatment resulted in translocations of GFP-PKCε from the cytosol to the plasma membrane. To investigate the role of DAG-dependent PKCs in carbachol-stimulated ERK1/2 activation, MIN6 cells were treated with carbachol or TPA in the absence or presence of the PKC inhibitors, bisindolylmaleimide I (BIM I), Ro 32-0432 and Gö 6976, which inhibit both conventional and novel PKCs [28–30]. In addition, MIN6 cells were stimulated with TPA overnight to down-regulate the expression of all DAG-dependent PKCs [24, 27] before treatment with carbachol or TPA. None of the PKC inhibitors, or chronic TPA pre-treatment, significantly inhibited carbachol-induced ERK1/2 activation (Fig. 3c), whereas each manipulation substantially inhibited acute TPA-stimulated ERK1/2 activation (Fig. 3d).

Increases in [Ca²⁺], are essential for carbachol-stimulated ERK1/2 phosphorylation.

Carbachol stimulated concentration-dependent increases in [Ca²⁺], that paralleled ERK1/2 activation (Fig. 1b, c). To determine whether this increase in [Ca²⁺], was essential for ERK1/2 activation, MIN6 cells were loaded with the Ca²⁺ chelator BAPTA-AM prior to carbachol addition. BAPTA-AM substantially attenuated carbachol-induced ERK1/2 activation (Fig. 4a) and abolished the agonist-stimulated change in [Ca²⁺], (Fig. 4b). Incubation of MIN6 cells in EGTA-buffered KRB (resulting in a [Ca²⁺] of approx. 100
nM abolishing the transmembrane \([Ca^{2+}]\) gradient) inhibited both carbachol-stimulated ERK1/2 activation (Fig. 4c) and the increase in \([Ca^{2+}]_i\) (Fig. 4d). Therefore, carbachol-stimulated ERK1/2 activation is dependent on an increase in \([Ca^{2+}]_i\), which is primarily dependent on Ca\(^{2+}\) influx.

Investigating the mechanism of carbachol-induced increases in \([Ca^{2+}]_i\) and ERK1/2 phosphorylation

To investigate how carbachol elicits an increase in \([Ca^{2+}]_i\) and to gain an insight into how this may lead to ERK1/2 activation, MIN6 cells were pre-incubated for 1 h in KRB-minus-glucose prior to treatment with a carbachol (1 mM) or TPA (1 \(\mu M\)). Changes in fluorescence intensity were expressed relative to initial fluorescence \((F/F_0)\). c, d MIN6 cells pre-treated in the absence or presence of TPA (1 \(\mu M\)) for 16 h (TPA o/n) were pre-incubated for 1 h in KRB-minus-glucose prior to treatment with c carbachol (1 mM, 2 min) or d TPA (1 \(\mu M\), 60 min) in the absence or presence of bisindolylmaleimide I (BIM, 1 \(\mu M\)), Ro 32-0432 (Ro32, 1 \(\mu M\)), or Go6976 (Go69, 1 \(\mu M\)). Proteins were separated by SDS–PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. Representative blots are shown above with mean data densitometry below in panels c and d. Data are shown as means ± SEM \((n = 3)\); ***\(P < 0.001\) by Dunnett’s range test following one-way ANOVA compared to carbachol (panel c) or TPA (panel d).
with these inhibitors and the [Ca$_{\text{ER}}^{2+}$] within the endoplasmic reticulum lumen ([Ca$_{\text{ER}}^{2+}$]) measured using the D1ER FRET sensor [20]. Stimulation of MIN6 cells with carbachol caused a decrease in [Ca$_{\text{ER}}^{2+}$] (Fig. 5c), which was prevented by xestospongin C (Fig. 5c). In contrast, 2-APB had no significant effect on carbachol-induced decreases in [Ca$_{\text{ER}}^{2+}$], demonstrating that it is not effective in MIN6 cells as an IP$_3$ receptor antagonist. Therefore, the inhibitory effect of 2-APB on carbachol-induced ERK1/2 activation and Ca$^{2+}$ mobilization is likely to be occurring through an action at SOCs, another known target of this inhibitor [31].

Although we have demonstrated that IP$_3$ receptor antagonism prevents carbachol-induced ERK1/2 activation in MIN6 cells, pre-treatment of MIN6 cells with thapsigargin failed to inhibit carbachol-stimulated ERK1/2 activation (Fig. 5d), yet significantly lowered the peak [Ca$_{\text{i}}^{2+}$]$_{\text{ER}}$ response (Fig. 5b). To determine whether thapsigargin is emptying ER stores of Ca$^{2+}$, MIN6 cells were pre-incubated with 1 μM thapsigargin for 10 min and [Ca$_{\text{ER}}^{2+}$] measured (Fig. 5f). This resulted in a decrease in [Ca$_{\text{ER}}^{2+}$]. Yet, the subsequent application of carbachol did not lead to a further decrease in [Ca$_{\text{ER}}^{2+}$], indicating that thapsigargin had indeed depleted the ER of Ca$^{2+}$. So why is pre-treatment with thapsigargin unable to inhibit carbachol-stimulated ERK1/2 activation? One explanation for this apparent paradox is that thapsigargin unable to inhibit carbachol-stimulated ERK1/2 activation? One explanation for this apparent paradox is that thapsigargin is increasing the [Ca$_{\text{i}}^{2+}$]$_{\text{ER}}$ sufficiently to compensate for the loss of IP$_3$-mediated Ca$^{2+}$ efflux from the ER. To investigate this possibility, changes in [Ca$_{\text{i}}^{2+}$]$_{\text{ER}}$ were measured during the thapsigargin pre-treatment and on subsequent carbachol addition. Indeed, it was shown that thapsigargin

Fig. 4 Ca$^{2+}$ influx across the plasma membrane is required for carbachol-stimulated ERK1/2 activation. a MIN6 cells were pre-incubated for 30 min in KRB-minus-glucose and, where indicated, loaded with BAPTA-AM (100 μM, BAPTA) for 30 min. Cells were then treated with carbachol (1 mM, 2 min). Proteins were separated by SDS–PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. A representative blot is shown above with mean data densitometry below. Data are shown as means SEM (n = 3); ***P < 0.001 by Dunnett’s range test following one-way ANOVA compared to carbachol. b Cells were loaded with Fluo-4-AM (2 μM) at the same time as BAPTA-AM and [Ca$_{\text{i}}^{2+}$] measured using single-cell confocal Ca$^{2+}$ imaging following carbachol (1 mM) addition. Data represent means SEM for the increase in [Ca$_{\text{i}}^{2+}$] (n > 30). c MIN6 cells were pre-incubated for 30 min in KRB-minus-glucose and, where indicated, incubated in EGTA-buffered KRB for the last 10 min. The Ca$^{2+}$ concentration in the KRB was reduced to ≤ 100 nM by EGTA-buffering and confirmed using Fura-2 free acid and standard fluorimetry. Carbachol (1 mM) was added to the KRB for 2 min. Proteins were separated by SDS–PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. A representative blot is shown above with densitometry below. Data are shown as means SEM (n > 3); ***P < 0.001 by Dunnett’s range test following one-way ANOVA compared to carbachol. d Changes in [Ca$_{\text{i}}^{2+}$]$_{\text{ER}}$ were assessed by single-cell confocal Ca$^{2+}$ imaging reproducing the experimental conditions used in panel e.
pre-incubation caused a significant increase in $[Ca^{2+}]_i$ levels over the 10-min period (Fig. 5g), yet carbachol-stimulated increases in $[Ca^{2+}]_i$ were unaffected. Therefore, it is possible that the increase in $[Ca^{2+}]_i$ caused by thapsigargin pre-treatment is sufficient to recapitulate IP₃ receptor-mediated $[Ca^{2+}]_{ER}$ release evoked on carbachol.
Fig. 5 Multiple Ca$^{2+}$ sources are required for carbachol-stimulated ERK1/2 activation. a MIN6 cells were pre-incubated for 1 h with KRB-minus-glucose in the absence or presence of 2ABP (10 μM) for 30 min, or nifedipine (10 μM), xestospongin C (10 μM) or diazoxide (250 μM) for 10 min prior to carbachol (1 mM, 2 min) addition. Proteins were separated by SDS-PAGE and detected by Western blotting using anti-phospho-ERK1/2 and anti-ERK2 antibodies. A representative blot is shown above with mean data densitometry below. Data are shown as means SEM (n = 3); *P < 0.05; ***P < 0.001 by Dunnett’s range test following one-way ANOVA compared to carbachol addition. b [Ca$^{2+}$], was monitored in populations of MIN6 cells pre-treated as in a by NOVOstar platereader. Data are shown as means SEM (n = 3); *P < 0.05; ***P < 0.001 by Dunnett’s range test following one-way ANOVA compared to carbachol addition. c MIN6 cells transfected with the cameleon D1ER construct were pre-incubated for 1 h in KRB-minus-glucose. Cells were then incubated in the absence or presence of 2ABP (10 μM) or xestospongin C (10 μM) for 10 min before the addition of carbachol (Cch, 1 mM). Data shown represent peak FRET changes following one-way ANOVA compared to carbachol addition. d MIN6 cells were transfected with cameleon D1ER construct were pre-incubated for 1 h in KRB-minus-glucose. Cells were then incubated in the absence or presence of thapsigargin (1 μM) for 10 min. A representative blot is shown above with mean data densitometry below. e MIN6 cells were maintained in KRB in which Na$^+$ was replaced by methylglucamine for 15 min before stimulation with either glucose (20 mM) or carbachol (1 mM). Data are shown as means SEM (n = 3); *P < 0.05; ***P < 0.001 by Dunnett’s range test following one-way ANOVA compared to carbachol addition. f MIN6 cells transfected with cameleon D1ER were pre-incubated for 1 h in KRB-minus-glucose prior to recording. All recordings show 1 min of basal KRB perfusion before either no pre-treatment or thapsigargin (1 μM) addition for 10 min followed by the addition of carbachol (1 mM) for 5 min. Data shown represent mean changes in fluorescence (n ≥ 50 cells). g MIN6 cells were pre-incubated in KRB-minus-glucose and then treated with carbachol (1 mM, black line) or thapsigargin (1 μM, gray line) for 10 min followed by the addition of carbachol (1 mM). Fluorescence was measured as an indicator of [Ca$^{2+}$]$_i$, by NOVOstar platereader for 10 s before initial Cch/thapsigargin pre-treatments.

Discussion

The present study provides evidence that carbachol, through the activation of a G$_a$-coupled mAChR, results in a transient MEK-dependent phosphorylation of ERK1/2 in the pancreatic β-cell line MIN6. We show that carbachol-induced activation of ERK is independent of both the activation of novel and classical PKCs, but is dependent on an increase in [Ca$^{2+}$]$_i$. We also show that this increase in [Ca$^{2+}$]$_i$ is likely mediated by both an IP$_3$-dependent efflux of Ca$^{2+}$ from the endoplasmic reticulum and the influx of extracellular Ca$^{2+}$ through both store-operated (SOC) and L-type voltage-operated (VOC) Ca$^{2+}$ channels (see Fig. 7).

mAChR activation in MIN6 cells leads to an IP$_3$ receptor-dependent efflux of Ca$^{2+}$ from the ER. This is
required for, but is not sufficient to cause, the activation of ERK1/2, as carbachol-stimulated ERK1/2 activation also requires the influx of extracellular Ca\(^{2+}\). This influx of Ca\(^{2+}\) is likely via SOCs and L-type VOCs as the increase in [Ca\(^{2+}\)]\(_i\), and indeed ERK1/2 phosphorylation, is blocked by either 2-APB (an inhibitor of SOCs, which does not inhibit IP\(_3\) receptors in this cell type) or nifedipine (an L-type VOC antagonist). As depolarization is a prerequisite for L-type VOC activation and carbachol-stimulated increases in [Ca\(^{2+}\)]\(_i\), are nifedipine-sensitive, carbachol must induce membrane depolarization. This is likely mediated by multiple mechanisms, including K\(_{ATP}\) channel...
Fig. 7 Schematic synopsis of the mechanisms of carbachol-stimulated ERK1/2 activation in MIN6 cells. (1) Agonist binding to the mAChR activates PLC resulting in phosphoinositide hydrolysis and the production of IP$_3$; (2) activation of IP$_3$R in the ER increases cytoplasmic [Ca$^{2+}$]; (3) plasma membrane store-operated channels mediate Ca$^{2+}$ entry; (4) K$_{ATP}$ channels are inactivated; (5) steps 2–4 converge resulting in depolarization and Ca$^{2+}$ entry through L-type VGCCs. The increase in [Ca$^{2+}$], results in ERK1/2 activation closure, Ca$^{2+}$ release from the ER via IP$_3$ receptors, and Ca$^{2+}$ influx via SOCS, as both carbachol-stimulated ERK1/2 phosphorylation and increased [Ca$^{2+}$], are significantly inhibited by diazoxide, 2APB and xestospongin C. These results are in general agreement with, and extend, previous observations showing that mAChR activation, in the absence of glucose, stimulates increases in [Ca$^{2+}$], via VOCs in both primary mouse β-cells and rat islets [32, 34].

The molecular mechanism of K$_{ATP}$ channels closure in response to carbachol treatment is unknown. However, one possibility is that carbachol activation of PLCβ could lead to a decrease in plasma membrane PIP$_2$ levels, which is known to regulate K$_{ATP}$ channel activity in pancreatic β-cells [33–35]. mAChR stimulation clearly causes increased phosphoinositide turnover as indicated by the plasma membrane-to-cyttoplasm translocation of eGFP-PH and increased accumulation of [3H]IP$_3$ in MIN6 cells. Yet, we could only detect relatively small decreases in PIP$_2$, and it is unclear whether this would be sufficient to significantly alter K$_{ATP}$ channel activity. Changes in PIP$_2$ levels were relatively greater, indicating that PIP$_2$ levels may be protected at the expense of PIP during mAChR stimulation in MIN6 cells. In another cell type, the human neuroblastoma SH-SY5Y, which endogenously expresses M$_3$ mAChRs, agonist addition stimulates much greater changes in PIP/PIP$_2$ levels (70–80% decreases) [25]. Nevertheless, it must be acknowledged that the methods used here are measuring global changes in PIP$_2$, and it is possible that within the immediate vicinity of the activated mAChR, the changes in polyphosphoinositide levels may be greater. At present, there is no evidence that mAChRs and the signal transduction machinery necessary to modulate K$_{ATP}$ are brought together within a microenvironment such as a lipid raft, but intriguingly the disruption of β-cell lipid rafts modifies Kv2.1 channel gating [42]. Therefore, it remains a possibility that changes in PIP$_2$ and/or PIP concentration affect ion channel activity, and hence the activation of ERK1/2.

SOC channel activation is dependent on IP$_3$-mediated Ca$^{2+}$ release from the ER [43–45]. Therefore, mAChR activation of SOC in MIN6 cells is also likely to be mediated by IP$_3$ receptor activation. mAChR activation has been shown to stimulate “capacitative” (ER store-depletion-driven) Ca$^{2+}$ entry in HIT-T15 cells and mouse pancreatic β-cells through the emptying of intracellular Ca$^{2+}$ stores [46]. Capacitative Ca$^{2+}$ entry has been reported to be relatively small in pancreatic β-cells, and, unlike other systems, it is not dependent on the energy status of the cell or PKC activation and is unaffected by protein phosphatase or tyrosine kinase inhibition [47]. However, capacitative Ca$^{2+}$ entry does affect membrane potential and could therefore influence the activity of the VOCs [48–50].

Our group had previously reported that GLP-1 stimulates ERK activation in MIN6 cells via Ca$^{2+}$ influx through L-type VOCs and that this is mediated by a Ras-independent mechanism [23]. Interestingly, carbachol-stimulated ERK activation also requires the activation of L-type VOCs and is in part independent of Ras activation. Therefore, it is likely that this Ras-independent Ca$^{2+}$-dependent ERK1/2 activation is mediated by L-type VOC signaling to ERK [23]. A proportion of carbachol-stimulated ERK1/2 activation is both Ras- and Ca$^{2+}$-dependent: this could be occurring through the activation of Ca$^{2+}$-dependent guanine nucleotide exchange factors (GEFs) for Ras such as Ras-GRP/Ras-GRF [51, 52].

The role of mAChR activation of ERK1/2 in pancreatic β-cells is currently unknown. However, the activation of ERK1/2 in β-cells, elicited by various nutrients and hormones, has been shown to be important in the stimulation of pancreatic β-cell proliferation, differentiation, survival, and gene transcription [15, 16, 53]. Intriguingly, M$_1$ and M$_3$ mAChR expression has been reported to be up-regulated and to stimulate islet cell proliferation during pancreatic regeneration [54], indicating that mAChR activation, possibly through the activation of ERK1/2, may play a positive role in β-cell proliferation. Moreover, in MIN6 cells, glucose-stimulated ERK1/2 activation has been shown to play an important role in enhancing insulin exocytosis, via the phosphorylation of synapsin I [18]. Therefore, it is also possible that mAChR activation of ERK plays a role in receptor-mediated potentiation of glucose-stimulated insulin secretion.

Acknowledgments We would like to thank Dr. Edith Gomez for critical reading of this manuscript and Dr. Gary B Willars for technical and statistical advice. This work was supported by a Diabetes UK studentship awarded to TPH (grant number 04/0002980).
Conflict of interest There is no conflict of interest that could be perceived as prejudicing the impartiality of the research reported.
