ABSTRACT

BACKGROUND AND PURPOSE: Previous studies of geometric and morphologic parameters of intracranial aneurysms have been conducted to determine rupture risk, which remains incompletely defined due to patient-specific risk factors, such as sex, hypertension, and age. To this end, we compared characteristics of ruptured and unruptured aneurysms in the same patients with symmetric bilateral intracranial aneurysms.

MATERIALS AND METHODS: Between January 2008 and March 2014, 2361 patients with 2674 aneurysms were diagnosed by CT angiography or surgical findings at 4 medical centers. Geometric and morphologic parameters examined for symmetric bilateral intracranial aneurysms comprised aneurysm wall regularity, size, neck width, aspect ratio, size ratio, neck-to-parent artery ratio, and area ratio. Univariate and multivariate statistical analyses were performed to determine independent risk factors for rupture.

RESULTS: Sixty-three patients (48 women, 15 men; mean age, 62.5 ± 9.8 years) with symmetric bilateral aneurysms were eligible for the study and were included. The most frequent aneurysm location was the posterior communicating artery. Univariate analysis disclosed that aneurysm size, aspect ratio, size ratio, area ratio, and irregular wall differed between patients with ruptured and unruptured aneurysms. Multivariate analysis indicated that aspect ratio of ≥1.6 (adjusted OR, 9.521; 95% CI, 2.182–41.535), area ratio of ≥1.5 (adjusted OR, 4.089; 95% CI, 1.247–13.406), and irregular shape (adjusted OR, 10.443; 95% CI 3.394–32.135) were significant predictive factors for aneurysm rupture after adjustment for aneurysm size. CONCLUSIONS: An aspect ratio of ≥1.6, area ratio of ≥1.5, and irregular wall are associated with aneurysm rupture independent of aneurysm size and patient characteristics. These characteristics alone can help in distinguishing ruptured bilateral intracranial aneurysms from unruptured ones.

ABBREVIATIONS: A2 = area of parent artery within the neck; A1 = aneurysm area; AR = aspect ratio; SR = size ratio

Unruptured intracranial aneurysms are common lesions with a prevalence of 3%–7%.1,2 Aneurysm rupture is the primary cause of subarachnoid hemorrhage, leading to high morbidity and mortality. Meanwhile, prophylactic treatment of unruptured intracranial aneurysms is also associated with risks.3,4 Therefore, identification of the risk factors for aneurysm rupture is essential for both risk assessment and treatment.

Previous research on geometric parameters, including aspect ratio (AR), size ratio (SR), and aneurysm flow angles, has shown their association with aneurysm rupture.5–7 However, conclusions are confounded by patient-specific characteristics, such as hypertension, age, and history of subarachnoid hemorrhage from another aneurysm which, along with geographic region, have been identified as risk factors for aneurysm rupture.8–10 Hence, aneurysm-related factors need to be analyzed by comparing the aneurysm characteristics of ruptured and unruptured aneurysms in the same individual to identify risk factors in a case-control design. We conducted a multicenter, retrospective cohort study of intracranial aneurysms in the Chinese population. The objectives of the article were to elucidate the morphologic and geometric parameters that discriminate intracranial aneurysm rupture status in the same patient with symmetric bilateral intracranial aneurysms.
MATERIALS AND METHODS

Patient Selection and Data Collection

A retrospective analysis was performed in patients diagnosed with intracranial aneurysms from January 2008 to March 2014 who underwent CT angiography with at least 64 sections at 1 of our 4 affiliated hospitals. At each participating center, the institutional review board approved this cohort study. The requirement for informed consent was waived because no diagnostic tests other than routine clinical imaging were used in this study. Additionally, we did not conduct research outside our country of residence.

Patient exclusion criteria were the following: 1) fusiform, traumatic, or mycotic aneurysms; 2) insufficient image quality to evaluate aneurysm geometry and morphology and poorly defined wide-neck aneurysms; 3) inability to identify the location of the ruptured aneurysm on the basis of the pattern of hemorrhage on CT or neurosurgical findings; and 4) an intracranial aneurysm related to arteriovenous malformation.

Definition and Measurement of Morphologic and Geometric Parameters

For each patient with SAH, noncontrast CT and CTA images were evaluated on the workstation that came with the CT scanner for morphologic and geometric variables of aneurysms. Patients were routinely checked at each hospital every day for treatment planning of both ruptured and unruptured aneurysms. CTA was performed with an FOV of 160 mm and a section thickness of 0.5 or 0.625 mm reconstructed at 0.5 or 0.625 mm, resulting in a voxel size of 0.3 × 0.3 × 0.5 (or 0.625) mm. Noncontrast head CT images and neurosurgical findings were reviewed by a neuroradiologist (Z.-B.W., with 25 years of working experience in central nervous system vascular imaging), who was blinded to aneurysm size or maximum aneurysm height was defined as the aneurysm size. Aneurysm shape was categorized into “spheric” (defined as an aneurysm ratio of Hp to W or W to Hp of ≥80%), or “non-spheric”; the aneurysm wall was categorized as smooth (regular pouch without protrusions) or irregular (when blebs, lobes, or protrusions were present). Flow into the aneurysm was considered straight flow when the inflow angle was greater than the main branching angle; otherwise, it was considered as curved flow. If the inflow angle and the main branching angle showed <10° difference, flow was considered equivalent.

Statistical Analysis

SPSS 17.0 (IBM, Armonk, New York) and Excel 2007 (Microsoft, Redmond, Washington) were used for all statistical analyses. Quantitative data of each geometric parameter were presented in the form of mean ± SD (x ± s), calculated for the ruptured and unruptured groups, and were analyzed with a paired t test. For further analysis, the cutoff value was calculated by the receiver operating characteristic. The criteria of cut-point selection are...
when the value of \((\text{sensitivity} + \text{specificity} - 1)\) reaches its maximum. Conditional univariable logistic regression analysis was performed to calculate odds ratios of each geometric and morphologic parameter between the 2 groups, and adjusted ORs were taken into the calculation to adjust for aneurysm size, which is an established and strong predictor of aneurysm rupture. \(^{9,10,14}\) A \(P\) value \(\leq 0.05\) was regarded as statistically significant, and all tests were 2-sided.

### RESULTS

#### General Demographics

Among 2361 patients with 2674 aneurysms, 269 (11.4%) had multiple aneurysms and 84 (3.6%) had symmetric bilateral aneurysms. Of the 84 patients in the clinical trial, 21 were excluded for the following reasons: 1) inability to identify the location of the ruptured aneurysm based on the pattern of hemorrhage or neurosurgical findings \((n = 9)\); 2) insufficient CT angiography quality \((n = 3)\); 3) the presence of fusiform, mycotic, or dissecting aneurysms \((n = 5)\); and 4) aneurysm related to an arteriovenous malformation \((n = 4)\). Thus, 63 patients with 126 intracranial aneurysms were enrolled in this cohort. There were 15 (23.8%) men and 48 (76.2%) women, and their mean age was 62.5 ± 9.8 years. The most frequent location for the 126 intracranial aneurysms was at the posterior communicating artery \((n = 68)\), followed by the middle cerebral artery \((n = 34)\), the internal carotid artery \((n = 20)\), the anterior cerebral artery \((n = 2)\), and the vertebral artery \((n = 2)\).

Aneurysm size, AR, SR, and area ratio in the ruptured group were significantly different from those of the unruptured group \((P < .05\), Table 1\), while neck size, vessel diameter, inflow angle, parent-daughter angle, and neck-to-parent artery ratio were not \((P > .05)\). For further analysis, the cutoff value was calculated by the receiver operating characteristic \((\text{ROC})\) curve for aneurysm size, AR, SR, and area ratio were the following: 0.667 (95% CI, 0.571–0.762), 0.703 (95% CI, 0.612–0.794), 0.679 (95% CI, 0.585–0.773), and 0.695 (95% CI, 0.603–0.787), respectively. The receiver operating characteristic area for AR \((0.703; 95\% \text{ CI}, 0.612–0.794, P < .001\) tends to be larger than the area under the curve of the other parameters. AR had the highest area under the curve.

#### Irregular Wall and AR of Symmetric Bilateral Aneurysms Predict Rupture

Previous retrospective studies found that aneurysm wall irregularity is associated with increased risk of rupture, but they were not adjusted for aneurysm size. \(^{19,21}\) Recently, a large-cohort prospective study found that unruptured aneurysms with a daughter sac (an irregular protrusion of the wall of the aneurysm) are more likely to rupture than aneurysms with a regular shape. \(^{14}\) Our study shows that after adjustment for aneurysm size, AR and irregular shape are associated with aneurysm rupture. Previous studies on AR indicated conflicting results, finding a significant

### Table 1: Geometric parameters of ruptured and unruptured aneurysms (\(\bar{x} \pm s\))

| Geometric Parameters | Unruptured \((n = 63)\) | Ruptured \((n = 63)\) | \(P\) Value |
|----------------------|-------------------------|-----------------------|-------------|
| Neck size (mm)       | 3.1 ± 1.6               | 3.2 ± 1.2             | .783        |
| Aneurysm size (mm)   | 4.3 ± 2.2               | 5.3 ± 2.0             | .009        |
| Vessel diameter (mm) | 2.5 ± 0.6               | 2.4 ± 0.6             | .687        |
| \(\theta_1\)         | 121.4° ± 32.7°          | 130.8° ± 33.6°        | .104        |
| \(\theta_2\)         | 107.6° ± 26.6°          | 100.9° ± 27.1°        | .159        |
| AR                   | 1.3 ± 0.5               | 1.7 ± 0.6             | <.001       |
| SR                   | 1.7 ± 1.2               | 2.1 ± 0.9             | .029        |
| NPR                  | 1.4 ± 0.7               | 1.4 ± 0.6             | .805        |
| Area ratio           | 2.0 ± 2.0               | 2.9 ± 1.9             | .011        |

Note: \(\theta_1\) indicates flow angle; \(\theta_2\), parent-daughter angle; NPR, neck-to-parent artery ratio.

### ROC Curve

FIG 2. Graph depicting the receiver operating characteristic curves for aneurysm size, AR, SR, and area ratio in the symmetric bilateral aneurysm. The areas under the curve for aneurysm size, AR, SR, and area ratio are the following: 0.667 (95% CI, 0.571–0.762), 0.703 (95% CI, 0.612–0.794), 0.679 (95% CI, 0.585–0.773), and 0.695 (95% CI, 0.603–0.787), respectively. The receiver operating characteristic area for AR \((0.703; 95\% \text{ CI}, 0.612–0.794, P < .001\) tends to be larger than the area under the curve of the other parameters. AR had the highest area under the curve.

### Discussion

Unruptured intracranial aneurysms are common lesions, and aneurysm rupture can be catastrophic. \(^{2,3,10,12,14}\) Not all unruptured intracranial aneurysms will rupture, and the management of unruptured intracranial aneurysms remains controversial in neurosurgery. Reliable, simple-to-use predictors of higher rupture risk to aid in treatment decisions for unruptured intracranial aneurysms are not available. In previous studies, the decision-making process was based mainly on size, with the risk of rupture considered significantly increased for aneurysms of \(\geq 7\) mm. \(^{10,14,15}\) However, various authors have shown that a large proportion of ruptured aneurysms are, in fact, \(< 7\) mm. \(^{16–18}\) Our study indicates that the mean size of ruptured aneurysms is \(5.29\) mm (range, 2.0–11.3 mm). More often than not, the ruptured aneurysm is not the largest aneurysm. Factors beyond size may be more important in determining the actual rupture risk.

difference between the ruptured and unruptured groups, proving that AR is a relevant predictor in estimating the aneurysm rupture risk.6,19,22,31 The conflicting results can be explained by the lack of adjustment for patient-specific risk factors for aneurysm rupture and by the use of different imaging techniques and measurement methodology.22,27 Regarding AR, only 3 previous studies aimed to minimize the confounding factors by studying patients with multiple intracranial aneurysms. Two studies found that the AR of intracranial aneurysms correlates with aneurysm rupture, but the authors did not adjust for aneurysm size in the multivariable analysis.7,23 Our study is similar to a prior one that found that AR is associated with aneurysm rupture after adjusting for aneurysm size and location.22 Additionally, the critical AR for rupture has varied among previous studies, with AR cutoff values ranging from 1.3 to 1.8, and remains controversial.6,19,22,23,26 In our study, an AR of ≥1.6 was significantly associated with aneurysm rupture.

Previous studies on flow angle, parent-daughter angle, aneurysm width, and neck width have shown conflicting results, with insignificant or marginally significant $P$ values for aneurysm rupture.5,13,16,31–33 The conflicting results may be ascribed to limited follow-up data and differences in imaging techniques and measurement methodology. The area ratio takes into account the aneurysm itself (maximal perpendicular height and aneurysm width) and the local vessel (DV and neck width). Our study shows that the area ratio is associated with aneurysm rupture after adjusting for aneurysm size. More than 80% of all ruptured aneurysms had an area ratio of ≥1.5 (the optimal threshold distinguishing the ruptured from unruptured intracranial aneurysms), whereas 52.38% of all unruptured intracranial aneurysms had an area ratio less than the cutoff value. More important, the area ratio in the ruptured group (2.9 ± 1.9) is larger than that of the unruptured group (2.0 ± 2.0) ($P = .011$).

It has previously been shown that as the intracranial aneurysm enlarges, the blood flow velocity becomes slower within the intracranial aneurysm, reducing the wall shear stress and making the intracranial aneurysm prone to rupture.7,30,34,38 From the perspective of hemodynamics, aneurysm area is proportional to the volume of blood contained by the aneurysm per unit of time, and the area of the parent artery in the neck is proportional to the aneurysm blood flow per unit of time provided by the parent artery via the aneurysm neck. Equal $A_2$ values but higher $A_1$ values indicate a greater blood volume contained by the aneurysm per unit of time but slower blood flow velocity and lower mean wall shear stress in the aneurysm, making the risk of aneurysm rupture higher. As for conditions involving the same $A_1$ values but lower $A_2$ values, the parent artery provides a reduced volume of blood to the aneurysm via the aneurysm neck, resulting in a slower blood velocity of blood flow and lower mean wall shear stress in the aneurysm, which also cause a higher rupture risk.

**Limitations**
One should consider some limitations inherent to this study: This is a retrospective analysis, which could cause biased selection of patients who underwent CT angiography. We used CT angiography data in the research and did not compare results with catheter digital subtraction angiography, which traditionally has been considered the criterion standard for aneurysm detection. However, CT angiography has high sensitivity and specificity for the detection of intracranial aneurysms and good consistency.11,12,22,39 Hence, we believe that the chances of misdiagnosis of intracranial aneurysms by CT angiography should be acceptably small. Another limitation of is that the area ratio is a weak predictor with marginally significant odds ratios for aneurysm rupture, even after adjustment for aneurysm size, so a correlation analysis between the area ratio and hemodynamics is needed. Finally, aneurysm size, irregular shape, and area ratio might be a consequence rather than the cause of aneurysm rupture; therefore, a prospective study, involving a geometric model comparison of aneurysms before and after rupture, is necessary.

**CONCLUSIONS**
We compared the aneurysm characteristics of ruptured and unruptured aneurysms in the same patient, by using CT angiography images according to a standard measurement protocol. AR, irregular shape, and area ratio are independent risk factors for aneurysm rupture. Those aneurysm characteristics alone in the current study can be helpful in distinguishing the ruptured symmetric bilateral intracranial aneurysms from unruptured ones.
