ABSTRACT
Shivering during regional anesthesia is a common problem and is distressing for patients with variety of complications. Therefore this study was conducted to compare the efficacy, potency, hemodynamic effects and side effects of tramadol with that of meperidine for the control of shivering during Spinal Anaesthesia. Sixty patients of ASA physical status I or II, aged 18 to 65 years, undergoing routine surgery under spinal anaesthesia and developed shivering intraoperatively were randomly allocated to receive 0.5 mg/kg meperidine intravenously (Group A, n=30) or 0.5 mg/kg tramadol intravenously (Group B, n=30). Treatment that stopped shivering was considered to have been successful. The response rate was 100 % in both the groups. The time that elapsed from treatment to the time shivering ceased was 5.37±2.20 minutes for meperidine group and 5.87±2.92 minutes for tramadol group (p>0.05). The number of patients who assessed treatment efficacy as no, partial or marked improvement was 0, 2 and 28 for meperidine group and 0, 3 and 27 for tramadol group (p>0.05). Only two patients receiving meperidine developed pruritis and both the groups were similar in terms of Haemodynamic response. The result of this study concluded that tramadol (0.5 mg/kg) is as effective as meperidine (0.5 mg/kg) for treating post anaesthetic shivering with high safety profile.

INTRODUCTION

Postanesthetic shivering (PS) is distressing for the patients and may exacerbate postoperative pain, increase intracranial pressure, and induce cardiopulmonary complications. Although the etiology of PS is inadequately understood, various risk factors have been evaluated. Among these, hypothermia, stress, uncontrolled pain, uninhibited spinal reflexes, and decreased sympathetic activity are frequently mentioned. Regional anesthesia produces vasodilatation, which facilitates core-to-peripheral redistribution of heat and the cool periphery is warmed at the expense of the core compartment. Thus, hypothermia from epidural or spinal anesthesia results from redistribution of heat from the core to the periphery. Many physical methods like, active and passive warming systems, warming of inspired air, warming systems for IV fluids, blood and its products are tried in many studies, however these methods require use of specialised equipment, which is not economically feasible and practical in all clinical settings.

Therefore pharmacological methods are used which are cost effective compared to physical methods. Many drugs have been used to treat PS, including meperidine, doxapram, tramadol, ketanserin, clonidine, propofol, physostigmine and nefopam. Among these drugs, meperidine is often recommended for PS. Although its mechanism of action is not fully elucidated, much evidence suggests the drug’s special antishivering activity is mediated by its k-opioid receptor activity. Meperidine is more effective in treating shivering than equi-analgesic doses of µ-receptor agonists, such as morphine, fentanyl, alfentanil, and sufentanil. Tramadol hydrochloride, a centrally-acting analgesic drug, is effective in the treatment of shivering after epidural anesthesia (EA) in parturients. In addition to a µ-opioid agonist effect, it exerts a modulatory effect on central monoaminergic pathways, inhibiting the neuronal uptake of noradrenaline and serotonin.

Hence this study was conducted to compare the efficacy, potency, hemodynamic effects and side effects of tramadol with that of meperidine for the control of shivering during Spinal Anaesthesia.

MATERIALS AND METHODS

This study was carried out at Nepal Medical College Teaching Hospital after approval from Nepal Medical College Institutional Review Committee. Written informed consent was taken from all patients who participated in the study. Sixty patients of ASA physical status I or II, aged 18 to 65 years, undergoing routine surgery under spinal anaesthesia and developed shivering intraoperatively were included in the study. Patients with hyperthyroidism, cardiopulmonary or neuromuscular disease and patients contraindicated to meperidine, tramadol and spinal anaesthesia were excluded from the study. Shivering was graded with a scale similar to that validated by Crossley and Mahajan as follows.

0 = No shivering
1 = Piloerection (no visible shivering)
2 = Muscular activity in only 1 muscle group
3 = Muscular activity in more than 1 muscle group but not generalized shivering
4 = Shivering involving the whole body

Only patients who developed Grade 3 or 4 shivering were included. The temperature of the operating room was maintained at 21 to 23 degree Celsius. Standard monitoring was used.

Spinal anaesthesia was given at lumbar vertebrae 3-4 or 4-5 interspace, with 0.5% bupivacaine heavy. All preloading fluids and drugs were used at room temperature. The administration of pre or intraoperative opioids was not permitted. Patients who shivered during surgery under spinal anaesthesia and requested antishivering treatment were randomly allocated to one of two groups for intravenous treatment: Group A (n=30) received Meperidine 0.5 mg/kg, and Group B (n=30) received Tramadol hydrochloride 0.5 mg/kg. Patients did not know which drug was administered. The anaesthesiologist who were unaware of the patients group and treatment, measured the time elapsed from treatment to the time when shivering ceased. If shivering did not cease after 15 min, the treatment was regarded as ineffective. Treatment efficacy was evaluated subjectively by the patients as no improvement, partial improvement, or marked improvement. Side effects, such as pruritus, somnolence (mildly sedated but easily aroused or heavily sedated), dizziness, nausea, vomiting, and respiratorydepression were recorded. Vital signs were measured before and 5 min after spinal anaesthesia, as well as 5 min after treatment. Statistical Analysis was performed using SPSS 16 software. P<0.05 was considered statistically significant.

RESULTS

The two groups did not differ significantly with respect to age, gender, ASA physical status, base line heart rate(HR), systolic blood pressure(SBP) and diastolic blood pressure(DBP) Table 1.
Mean onset time of shivering after Spinal Anaesthesia in meperidine group was 12.63 ± 7.17 minutes and tramadol group was 13.70 ± 9.75 min (Table 2).

The Response rate (shivering cessation after treatment within 15 minutes) was 100% in both the groups (Table 3).

The time that elapsed from treatment to the time shivering ceased was 5.37 ± 2.20 minutes for Meperidine group and 5.87 ± 2.92 minutes for Tramadol group (Table 4).

The number of patients who assessed treatment efficacy as no, partial or marked improvement was 0, 2 and 28 for Meperidine group and 0, 3 and 27 for Tramadol group which did not differ significantly (Table 5).

Two patients treated with meperidine developed wheals, flare and itching in the skin around the vein being injected. Other side effects, such as nausea, vomiting, dizziness, somnolence and respiratory depression did not occur. The reaction faded itself within 10 minutes without any treatment. No any side effects occurred in patient treated with Tramadol (Table 6).

In addition, the vital parameters such as heart rate and arterial blood pressure were not significantly different, 5 minutes after Spinal Anaesthesia and 5 minutes after treatment for shivering with Meperidine or Tramadol except in post treatment systolic blood pressure which showed significant difference between two groups (Table 7).
DISCUSSION

Shivering during regional anesthesia is a common problem and up to 56.7% incidence of shivering during regional anesthesia has been reported.25,26 Among all the drugs Meperidine and Tramadol are found to be most effective to control shivering. Tramadol with less respiratory depression and sedation has been used in controlling shivering and hence is a safe drug for treatment of post anesthetic shivering.20 Pethidine is one of the most effective drugs for control of postanesthetic shivering and is widely used for the purpose.27 Hence in this study we have compared Tramadol, a newer synthetic opioid with Pethidine, which is the gold standard drug for treatment of postanaesthetic shivering, in search for more safe and efficacious drug.

In this study the two groups were similar in terms of age, sex, ASA physical status, base line heart rate, systolic and diastolic blood pressure and onset time of shivering after spinal anaesthesia. Therefore these groups were comparable.

Different doses of Tramadol from 0.2 mg/kg to 3mg/kg were used to control postoperative shivering in different studies.27-29 Wrench et al20 suggested that the minimal effective dose of meperidine for treating PS is approximately 0.35 mg/kg. In this study we used tramadol 0.5mg/kg and meperidine 0.5 mg/kg which was effective in controlling shivering in 100 % of patients in both the groups. The response rate ie, shivering ceased after treatment in a study conducted by Tsai et al31 was only 87% for tramadol group and 93% for meperidine group in similar dose as compared to our study.

In this study, the time taken for shivering cessation after treatment with Meperidine was 5.37±2.20 minutes and with Tramadol was 5.87±2.92 minutes which was statistically similar. Similar findings were reported in a study done by Tsai et al.31 Studies from Dhimar et al15 and Talakoub et al32 showed that Tramadol is better than pethidine for controlling PS. Many studies have demonstrated the usefulness of tramadol in control of shivering, studies have also demonstrated that, tramadol is more effective in treatment of shivering when compared to other drug like Pethidine.28,32-35 In this study we found that tramadol is as effective as meperidine in treatment of PS.

In this study, two patients receiving meperidine developed wheals flare and itching in the skin around the vein being injected whereas patients receiving tramadol did not have any side effects. Disadvantages of meperidine treatment are the side effects of sedation and respiratory depression, which may be induced with previously administered opioids or anesthetics. In the study conducted by Tsai et al31 the incidence of somnolence in the group that received meperidine (33%) was more frequent than in those who received tramadol (7%) or amitriptyline (0%). Pruritus, nausea, and vomiting were also important potential side effects but did not occur frequently with the dosage used. Because both tramadol and meperidine have similar shivering quenching effects, whereas tramadol has a decreased incidence of central depressive effects, they concluded that tramadol should be considered superior to meperidine for the treatment of shivering.

|                         | Group     | Mean   | Std. Deviation | p-value |
|-------------------------|-----------|--------|----------------|---------|
| Post spinal HR(min)     | Meperidine| 76.73  | 11.169         | 0.682   |
|                         | Tramadol  | 78.20  | 16.014         |         |
| Post spinal SBP(mm Hg)  | Meperidine| 112.60 | 11.128         | 0.360   |
|                         | Tramadol  | 115.33 | 11.807         |         |
| Post spinal DBP(mm Hg)  | Meperidine| 67.27  | 12.996         | 0.628   |
|                         | Tramadol  | 68.77  | 10.766         |         |
| Post treatment HR(min)  | Meperidine| 74.70  | 9.326          | 0.569   |
|                         | Tramadol  | 76.23  | 11.307         |         |
| Post treatment SBP(mm Hg)| Meperidine| 113.20 | 9.810          | 0.013   |
|                          | Tramadol  | 119.90 | 10.496         |         |
| Post treatment DBP(mm Hg)| Meperidine| 69.73  | 11.441         | 0.541   |
|                          | Tramadol  | 71.50  | 10.789         |         |
The vital parameters were similar in both the groups except the post treatment systolic blood pressure. It was 113.20±9.81 mmHg in meperidine group and 119.90±10.496 mmHg in tramadol group. Though statistics showed significant change it is within normal range in both the groups. The result of this study indicates that tramadol (0.5mg/kg) is as effective as meperidine (0.5mg/kg) for treating post anaesthetic shivering with high safety profile.
