Abstract

This paper introduces a new measure-conjugacy invariant for actions of free groups. Using this invariant, it is shown that two Bernoulli shifts over a finitely generated free group are measurably conjugate if and only if their base measures have the same entropy. This answers a question of Ornstein and Weiss.
A measure-conjugacy invariant for free group actions

Lewis Bowen

October 26, 2008

Keywords: Ornstein’s isomorphism theorem, Bernoulli shifts, measure conjugacy.
MSC:37A35

1 Introduction

This paper is motivated by an old and central problem in measurable dynamics: given two dynamical systems, determine whether they are measurably-conjugate, i.e., isomorphic. Let us set some notation.

A dynamical system (or system for short) is a triple \((G, X, \mu)\) where \((X, \mu)\) is a probability space and \(G\) is a group acting by measure-preserving transformations on \((X, \mu)\). We will also call this a dynamical system over \(G\), a \(G\)-system or an action of \(G\). In this paper, \(G\) will always be a discrete countable group. Two systems \((G, X, \mu)\) and \((G, Y, \nu)\) are isomorphic (i.e., measurably conjugate) if and only if there exist conull sets \(X' \subset X, Y' \subset Y\) and a bijective measurable map \(\phi: X' \to Y'\) such that \(\phi^{-1}\) is measurable, \(\phi_* \mu = \nu\) and \(\phi(gx) = g\phi(x)\forall g \in G, x \in X'\).

A special class of dynamical systems called Bernoulli systems or Bernoulli shifts has played a significant role in the development of the theory as a whole; it was the problem of trying to classify them that motivated Kolmogorov to introduce the mean entropy of a dynamical system over \(\mathbb{Z}\) [Ko58, Ko59]. That is, Kolmogorov defined for every system \((\mathbb{Z}, X, \mu)\) a number \(h(\mathbb{Z}, X, \mu)\) called the mean entropy of \((\mathbb{Z}, X, \mu)\) that quantifies, in some sense, how “random” the system is. See [Ka07] for a historical survey.

Bernoulli shifts also play an important role in this paper, so let us define them. Let \((K, \kappa)\) be a standard Borel probability space. For a discrete countable group \(G\), let \(K^G = \prod_{g \in G} K\) be the set of all functions \(x: G \to K\) with the product Borel structure and let \(\kappa^G\) be the product measure on \(K^G\). \(G\) acts on \(K^G\) by \((gx)(f) = x(g^{-1}f)\) for \(x \in K^G\) and \(g, f \in G\). This action is measure-preserving. The system \((G, K^G, \kappa^G)\) is the Bernoulli shift over \(G\) with base \((K, \kappa)\). It is nontrivial if \(\kappa\) is not supported on a single point.
Before Kolmogorov’s seminal work \cite{Ko58, Ko59}, it was unknown whether all non-trivial Bernoulli shifts over \( \mathbb{Z} \) were measurably conjugate to each other. He proved that \( h(\mathbb{Z}, K^\mathbb{Z}, \kappa^\mathbb{Z}) = H(\kappa) \) where \( H(\kappa) \), the \textbf{entropy of} \( \kappa \) is defined as follows. If there exists a finite or countably infinite set \( K' \subset K \) such that \( \kappa(K') = 1 \) then
\[
H(\kappa) = - \sum_{k \in K'} \mu(\{k\}) \log(\mu(\{k\}))
\]
where we follow the convention \( 0 \log(0) = 0 \). Otherwise, \( H(\kappa) = +\infty \). Thus two Bernoulli shifts over \( \mathbb{Z} \) with different base measure entropies cannot be measurably conjugate.

The converse was proven by D. Ornstein in the groundbreaking papers \cite{Or70a, Or70b}. That is, he proved that if two Bernoulli shifts \((\mathbb{Z}, K^\mathbb{Z}, \kappa^\mathbb{Z}), (\mathbb{Z}, L^\mathbb{Z}, \lambda^\mathbb{Z})\) are such that \( H(\kappa) = H(\lambda) \) then they are isomorphic.

In \cite{Ki75}, Kieffer proved a generalization of the Shannon-McMillan theorem to actions of a countable amenable group \( G \). In particular, he extended the definition of mean entropy from \( \mathbb{Z} \)-systems to \( G \)-systems. This leads to the generalization of Kolmogorov’s theorem to amenable groups.

In the landmark paper \cite{OW87}, Ornstein and Weiss extended most of the classical entropy theory from \( \mathbb{Z} \)-systems to \( G \)-systems where \( G \) is any countable amenable group. In particular, they proved that if two Bernoulli shifts \((G, K^G, \kappa^G), (G, L^G, \lambda^G)\) over a countably infinite amenable group \( G \) are such that \( H(\kappa) = H(\lambda) \) then they are isomorphic. Thus Bernoulli shifts over \( G \) are completely classified by base measure entropy.

Now let us say that a group \( G \) is \textbf{Ornstein} if \( H(\kappa) = H(\lambda) \) implies \((G, K^G, \kappa^G)\) is isomorphic to \((G, L^G, \lambda^G)\) whenever \((K, \kappa)\) and \((L, \lambda)\) are standard Borel probability spaces. By the above, all countably infinite amenable groups are Ornstein. Stepin proved that any countable group that contains an Ornstein subgroup is itself Ornstein \cite{St75}. It is unknown whether every countably infinite group is Ornstein.

In \cite{OW87}, Ornstein and Weiss asked whether all Bernoulli shifts over a nonamenable group are isomorphic. The next result shows that the answer is ‘no’:

\textbf{Theorem 1.1.} \textit{Let \( G = \langle s_1, \ldots, s_r \rangle \) be the free group of rank \( r \). If \((K_1, \kappa_1), (K_2, \kappa_2)\) are standard probability spaces with \( H(\kappa_1) + H(\kappa_2) < \infty \) then \((G, K_1^G, \kappa_1^G)\) is measurably conjugate to \((G, K_2^G, \kappa_2^G)\) if and only if \( H(\kappa_1) = H(\kappa_2) \).}

The reason Ornstein and Weiss thought the answer might be ‘yes’ is due to a curious example presented in \cite{OW87}. It pertains to a well-known fundamental property of entropy: it is nonincreasing under factor maps. Let \((G, X, \mu)\) and \((G, Y, \nu)\) be two systems. A map \( \phi : X \to Y \) is a factor if \( \phi_*\mu = \nu \) and \( \phi(gx) = g\phi(x) \) for a.e. \( x \in X \) and every \( g \in G \). If \( G \) is amenable then the mean entropy of a factor is less than or equal to the mean entropy of the source. This is essentially due to Sinai. So if \( K_n = \{1, \ldots, n\} \) and \( \kappa_n \) is the uniform probability measure on \( K_n \) then \((G, K_n^G, \kappa_n^G)\), which has entropy \( \log(2) \), cannot factor onto \((G, K_4^G, \kappa_4^G)\), which has entropy \( \log(4) \).

The argument above fails if \( G \) is nonamenable. Indeed, let \( G = \langle a, b \rangle \) be a rank 2 free group. Identify \( K_2 \) with the group \( \mathbb{Z}/2\mathbb{Z} \) and \( K_4 \) with \( \mathbb{Z}/2\mathbb{Z} \times \mathbb{Z}/2\mathbb{Z} \). Then
\[
\phi(x)(g) := (x(g) + x(ga), x(g) + x(gb)) \quad \forall x \in K_2^G, g \in G
\]
is a factor map from \((G, K^G_2, \kappa^G_2)\) onto \((G, K^G_4, \kappa^G_4)\). This is Ornstein-Weiss’ example. It is
the main ingredient in the proof of the next theorem, which will appear in a separate paper.

**Theorem 1.2.** Let \(G\) be any countable group that contains a nonabelian free subgroup. Then
every nontrivial Bernoulli shift over \(G\) factors onto every Bernoulli shift over \(G\).

To prove theorem [1.1] the following invariant is introduced. Let \((X, \mu)\) be any probability
space on which \(G = \langle s_1, \ldots, s_r \rangle\), the rank \(r\) free group, acts by measure-preserving transfor-
mations. Let \(\alpha = \{A_1, \ldots, A_n\}\) be a partition of \(X\) into finitely many measurable sets. Let
\(B(e, n) \subseteq G\) denote the ball of radius \(n\) centered at the identity element with respect to the
word metric induced by \(S = \{s_1^{\pm 1}, \ldots, s_r^{\pm 1}\}\). The join of two partitions \(\alpha, \beta\) of \(X\) is defined
by \(\alpha \lor \beta = \{A \cap B \mid A \in \alpha, B \in \beta\}\). Let
\[
H(\alpha) := -\sum_{A \in \alpha} \mu(A) \log(\mu(A)),
\]
\[
F(\alpha) := (1 - 2r)H(\alpha) + \sum_{i=1}^{r} H(\alpha \lor s_i \alpha),
\]
\[
\alpha^n := \bigvee_{g \in B(e, n)} g\alpha,
\]
\[
f(\alpha) := \inf \{F(\alpha^n)\}.
\]

A partition \(\alpha\) is **generating** if the smallest \(G\)-invariant \(\sigma\)-algebra containing \(\alpha\) is the \(\sigma\)-
algebra of all measurable sets (up to sets of measure zero). The main theorem of this paper is:

**Theorem 1.3.** Let \(G = \langle s_1, \ldots, s_r \rangle\). Let \((G, X, \mu)\) be a system. If \(\alpha\) and \(\beta\) are finite measur-
able generating partitions of \(X\) then \(f(\alpha) = f(\beta)\). Hence this number, denoted \(f(G, X, \mu)\),
is a measure-conjugacy invariant.

Theorem [5.2] below implies that if \(|K| < \infty\) then \(f(G, K^G, \kappa^G) = H(\kappa)\). This and Stepin’s
theorem proves theorem [1.1] A simple exercise reveals that if \(r = 1\), then \(f(G, X, \mu) = h(G, X, \mu)\) is Kolmogorov’s entropy.

Here is a brief outline of the paper. In the next section, standard entropy-theory def-
definitions are presented. In §3 an equivalence relation, called combinatorial equivalence, is
introduced on the space of finite partitions of \(X\), where \((X, \mu)\) is a standard probability
space on which a countable group \(G\) acts. We prove that the combinatorial equivalence class
of a finite generating partition is dense in the space of all generating partitions. In §4 we
introduce an operation on partitions called splitting and show that any two combinatorially
equivalent partitions have a common splitting. This culminates in a condition sufficient for
a function from the space of partitions to \(\mathbb{R}\) to induce a measure-conjugacy invariant. In §5
this condition is shown to hold for the function \(F\) defined above. This proves theorem [1.3]
Then we prove theorem [5.2] (that \(f(G, K^G, \kappa^G) = H(\kappa)\) if \(|K| < \infty\) and conclude theorem
[1.1]
Acknowledgments: I am grateful to Russell Lyons for suggesting this problem, for encouragements and for many helpful conversations. I would like to thank Dan Rudolph for pointing out errors in a preliminary version. I would like to thank Benjy Weiss for many comments that helped me to greatly improve the exposition of this paper and simplify several arguments.

2 Some Standard Definitions

For the rest of this section, fix a standard probability space \((X, \mu)\).

Definition 1. A partition \(\alpha = \{A_1, \ldots, A_n\}\) is a pairwise disjoint collection of measurable subsets \(A_i\) of \(X\) such that \(\bigcup_{i=1}^n A_i = X\). The sets \(A_i\) are called the partition elements of \(\alpha\). Alternatively, they are called the atoms of \(\alpha\). Unless stated otherwise, all partitions in this paper are finite (i.e., \(n < \infty\)).

If \(\alpha\) and \(\beta\) are partitions of \(X\) then we write \(\alpha = \beta\) a.e. if for all \(A \in \alpha\) there exists \(B \in \beta\) with \(\mu(A \Delta B) = 0\). Let \(\mathcal{P}\) denote the set of all a.e.-equivalence classes of finite partitions of \(X\). By a standard abuse of notation, we will refer to elements of \(\mathcal{P}\) as partitions.

Definition 2. If \(\alpha, \beta \in \mathcal{P}\) then the join of \(\alpha\) and \(\beta\) is the partition \(\alpha \vee \beta = \{A \cap B \mid A \in \alpha, B \in \beta\}\).

Definition 3. Let \(\mathcal{F}\) be a \(\sigma\)-algebra contained in the \(\sigma\)-algebra of all measurable subsets of \(X\). Given a partition \(\alpha\), define the conditional information function \(I(\alpha|\mathcal{F}) : X \to \mathbb{R}\) by
\[
I(\alpha|\mathcal{F})(x) = -\log \left( \mu(A_x|\mathcal{F})(x) \right)
\]
where \(A_x\) is the atom of \(\alpha\) containing \(x\). Here \(\mu(A_x|\mathcal{F}) : X \to \mathbb{R}\) is the conditional expectation of \(\chi_{A_x}\), the characteristic function of \(A_x\), with respect to the \(\sigma\)-algebra \(\mathcal{F}\).

The conditional entropy of \(\alpha\) with respect to \(\mathcal{F}\) is defined by
\[
H(\alpha|\mathcal{F}) = \int_X I(\alpha|\mathcal{F})(x) \, d\mu(x).
\]

If \(\beta\) is a partition then, by abuse of notation, we can identify \(\beta\) with the \(\sigma\)-algebra equal to the set of all unions of partition elements of \(\beta\). Through this identification, \(I(\alpha|\beta)\) and \(H(\alpha|\beta)\) are well-defined. Let \(I(\alpha) = I(\alpha|\{\emptyset, X\})\) and \(H(\alpha) = H(\alpha|\{\emptyset, X\})\).

Lemma 2.1. For any two partitions \(\alpha, \beta\) and for any two \(\sigma\)-algebras \(\mathcal{F}_1, \mathcal{F}_2\) with \(\mathcal{F}_1 \subset \mathcal{F}_2\),
\[
H(\alpha \vee \beta) = H(\alpha) + H(\beta|\alpha),
\]
\[
H(\alpha|\mathcal{F}_2) \leq H(\alpha|\mathcal{F}_1).
\]

Proof. This is well-known. For example, see [Gl03, Proposition 14.16, page 255]. \(\square\)
Definition 4 (Rokhlin distance). Define $d : \mathcal{P} \times \mathcal{P} \to \mathbb{R}$ by

$$d(\alpha, \beta) = H(\alpha|\beta) + H(\beta|\alpha) = 2H(\alpha \lor \beta) - H(\alpha) - H(\beta).$$

By [Pa69, theorem 5.22, page 62] this defines a distance function on $\mathcal{P}$. If $G$ is a group acting by measure-preserving transformations on $(X, \mu)$ then the action of $G$ on $\mathcal{P}$ is isometric. I.e., if $g \in G$, $\alpha, \beta \in \mathcal{P}$ then $d(g\alpha, g\beta) = d(\alpha, \beta)$. From now on, we consider $\mathcal{P}$ with the topology induced by $d(\cdot, \cdot)$.

Definition 5. Let $G$ be a group acting on $(X, \mu)$. Let $\alpha$ be a partition of $X$. Let $\Sigma_\alpha$ be the smallest $G$-invariant $\sigma$-algebra containing $\alpha$. Then $\alpha$ is generating if for any measurable set $A \subset X$ there exists a set $A' \in \Sigma_\alpha$ such that $\mu(A \Delta A') = 0$. Let $\mathcal{P}_{\text{gen}} \subset \mathcal{P}$ denote the set of all generating partitions.

3 Combinatorially Equivalent Partitions

For this section, fix a countable group $G$ and an action of $G$ on a standard probability space $(X, \mu)$ by measure-preserving transformations.

Definition 6. Given $\alpha \in \mathcal{P}$ and $F \subset G$ finite, let $\alpha^F = \bigvee_{f \in F} f\alpha$.

Definition 7. If $\alpha, \beta \in \mathcal{P}$ are such that for all $A \in \alpha$ there exists $B \in \beta$ with $\mu(A - B) = 0$ then we say that $\alpha$ refines $\beta$ and denote it by $\alpha \geq \beta$. Equivalently, $\beta$ is a coarsening of $\alpha$.

Definition 8. Let $\alpha, \beta \in \mathcal{P}$. We say that $\alpha$ is combinatorially equivalent to $\beta$ if there exist finite sets $L, M \subset G$ such that $\alpha \leq \beta^L$ and $\beta \leq \alpha^M$. Let $\mathcal{P}_{eq}(\alpha) \subset \mathcal{P}$ denote the set of partitions combinatorially equivalent to $\alpha$.

The goal of this section is to prove theorem 3.3 below: if $\alpha$ is a generating partition then $\mathcal{P}_{eq}(\alpha)$ is dense in the subspace of all generating partitions.

Lemma 3.1. Let $\alpha$ be a generating partition and $\beta = \{B_1, \ldots, B_m\} \in \mathcal{P}$. Let $\epsilon > 0$. Then there exists a partition $\beta' = \{B'_1, \ldots, B'_m\}$ and a finite set $L \subset G$ such that $\alpha^L \geq \beta'$ and for all $i = 1 \ldots m$, $\mu(B_i \Delta B'_i) \leq \epsilon$.

Proof. Since $\alpha$ is generating, there exists a finite set $L \subset G$ such that for every $i \in \{1, \ldots, m\}$, there is a set $B''_i$, equal to a finite union of atoms of $\alpha^L$, such that $\mu(B_i \Delta B''_i) < \frac{\epsilon}{m}$. For $i = 1 \ldots m - 1$, let

$$B'_i := B''_i - \bigcup_{j \neq i} B''_j.$$

$$B'_m := X - \bigcup_{i < m} B'_i = B''_m \cup \bigcup_{i \neq j} B'_i \cap B'_j.$$

Observe that for all $i = 1 \ldots m$,

$$B_i - \bigcup_j B''_j \Delta B_j \subset B'_i \subset B_i \cup \bigcup_j B''_j \Delta B_j.$$
Thus
\[ \mu(B'_i \Delta B_i) \leq m\left(\frac{\epsilon}{m}\right) = \epsilon. \]

By construction, \( \beta' = \{B'_1, \ldots, B'_m\} \leq \alpha^L. \)

\[ \square \]

**Lemma 3.2.** Let \( \alpha = \{A_1, \ldots, A_n\} \in \mathcal{P} \) and \( \beta \in \mathcal{P}_{gen}. \) Let \( \epsilon > 0. \) Then there exists a finite set \( M \subset G \) such that for all finite \( L \subset G \) with \( M \subset L, \) the partition elements \( \{B^L_1, \ldots, B^L_m\} \) of \( \beta^L \) can be ordered so that there exists an \( r \in \{1, \ldots, m_L\} \) and a function \( f : \{1, 2, \ldots, r\} \rightarrow \{1, 2, \ldots, n\} \) so that for all \( i \in \{1, \ldots, r\}, \)
\[
\frac{\mu(B^L_i \cap A_{f(i)})}{\mu(B^L_i)} \geq 1 - \epsilon
\]
and
\[
\mu\left(\bigcup_{i>r} B^L_i\right) < \epsilon.
\]

**Proof.** Let \( \delta > 0 \) be such that \( \delta < \left(\frac{\epsilon}{n}\right)^2. \) By the previous lemma, there exists a partition \( \alpha' = \{A'_1, \ldots, A'_n\} \in \mathcal{P} \) and a finite set \( M \subset G \) such that \( \alpha' \leq \beta^M \) and \( \mu(A'_i \Delta A_i) < \delta \) for all \( i. \) Let \( L \) be any finite subset of \( G \) with \( M \subset L. \)

Let \( \beta^L = \{B^L_1, \ldots, B^L_m\} \) and let \( f : \{1, \ldots, m_L\} \rightarrow \{1, \ldots, n\} \) be the function \( f(i) = j \) if \( \mu(B^L_i - A'_j) = 0. \) This is well-defined since \( \beta^L \) refines \( \alpha'. \)

After reordering the partition elements of \( \beta^L = \{B^L_1, \ldots, B^L_m\} \) if necessary, we may assume that there is an \( r \in \{0, \ldots, m_L\} \) such that, if \( r > 0 \) then for all \( i \leq r, \)
\[
\frac{\mu(B^L_i \cap A_{f(i)})}{\mu(B^L_i)} \geq 1 - \sqrt{\delta},
\]
and if \( i > r \) then
\[
\frac{\mu(B^L_i \cap A_{f(i)})}{\mu(B^L_i)} < 1 - \sqrt{\delta}.
\]

So if \( i > r \) then
\[
\mu(B^L_i \cap A_{f(i)}) < (1 - \sqrt{\delta})\mu(B^L_i).
\]

So
\[
\mu(B^L_i) = \mu(B^L_i - A_{f(i)}) + \mu(B^L_i \cap A_{f(i)}) < \mu(B^L_i - A_{f(i)}) + (1 - \sqrt{\delta})\mu(B^L_i).
\]

Solve for \( \mu(B^L_i) \) to obtain
\[
\mu(B^L_i) < \frac{1}{\sqrt{\delta}} \mu(B^L_i - A_{f(i)}).
\]
Since the atoms $B^L_i$ are pairwise disjoint, it follows that
\[
\mu \left( \bigcup_{i>r} B^L_i \right) < \frac{1}{\sqrt{\delta}} \mu \left( \bigcup_{i>r} B^L_i - A_{f(i)} \right).
\]
Since $\mu(B^L_i - A'_{f(i)}) = 0$, it must be that $B^L_i - A_{f(i)} \subset A'_{f(i)} - A_{f(i)}$, up to a set of measure zero. So,
\[
\mu \left( \bigcup_{i>r} B^L_i \right) \leq \frac{1}{\sqrt{\delta}} \mu \left( \bigcup_{i>r} A'_{f(i)} - A_{f(i)} \right) \leq n\sqrt{\delta} < \epsilon.
\]

**Theorem 3.3.** If $\alpha$ is a generating partition then
\[
P_{\text{gen}} \subseteq P_{\text{eq}}(\alpha).
\]
I.e., the subspace of partitions combinatorially equivalent to $\alpha$ is dense in the space of all generating partitions.

**Proof.** Let $\alpha = \{A_1, \ldots, A_n\}$ and $\beta = \{B_1, \ldots, B_m\} \in P_{\text{gen}}$. Without loss of generality, we assume that $\mu(A_i) > 0$ for all $i = 1 \ldots n$. Let $\epsilon > 0$. By the previous lemma, there exists a finite set $L \subset G$ such that the atoms of $\beta^L = \{B^L_1, \ldots, B^L_m\}$ can be ordered so that there exists an $r \in \{1, \ldots, m_L\}$ and a function $f : \{1, 2, \ldots, r\} \rightarrow \{1, 2, \ldots, n\}$ so that for all $i \in \{1, \ldots, r\}$,
\[
\frac{\mu(B^L_i \cap A_{f(i)})}{\mu(B^L_i)} \geq 1 - \epsilon
\]
and
\[
\mu \left( \bigcup_{i>r} B^L_i \right) < \epsilon. \tag{1}
\]

By choosing $\epsilon$ small enough (if necessary) we may assume that $f$ is onto (for example, by choosing $\epsilon$ to be smaller than $\frac{1}{2}\mu(A_j)$ over all $j = 1 \ldots n$).

By definition of $\beta^L$, $m_L \leq m{\mid L\mid}$. If necessary, we may assume that $m_L = m{\mid L\mid}$ after modifying $\beta^L$ by adding to it several copies of the empty set. That is, for some $i$, it may occur that $B^L_i = \emptyset$.

Let $\delta > 0$ be such that $\delta < \epsilon$. By lemma 3.1, there exists a partition $\gamma = \{C_1, \ldots, C_m\}$ and a finite set $M \subset G$ such that $\gamma \leq \alpha^M$ and $\mu(C_i \Delta B_i) < \delta$ for all $i$. By choosing $\delta$ small enough we may assume the following. Let $\gamma^L = \{C^L_1, \ldots, C^L_{m_L}\}$. Then, after reordering the atoms of $\gamma^L$ if necessary,
\[
\mu \left( \bigcup_{j=1}^{m_L} C^L_j - B^L_j \right) \leq \epsilon. \tag{2}
\]
Let

\[ C'_i = \{ x \in C_i \mid \text{if } x \in C'_j \text{ for some } j \text{ then } x \in A_{f(j)} \} \]

\[ = \bigcup_{j=1}^{m_i} C_i \cap C'_j \cap A_{f(j)}. \]

Let \( C_{i,j} = C_i \cap A_j - C'_i. \) Let

\[ \gamma_1 = \{ C'_i \mid i = 1 \ldots m \} \cup \{ C_{i,j} \mid 1 \leq i, j \leq m \}. \]

Note that \( \gamma_1 \leq (\alpha^M)^L = \alpha^{LM} \) where \( LM = \{ lm \mid l \in L, m \in M \}. \) We claim that \( \gamma_1 \) is combinatorially equivalent to \( \alpha. \) Let \( \Sigma_1 \) be the smallest \( G \)-invariant collection of subsets of \( X \) that is closed under finite intersections and unions and contains the atoms of \( \gamma_1. \) It suffices to show that every atom of \( \alpha \) is in \( \Sigma_1. \) Observe that, for each \( i, \) \( C_i = C'_i \cup \bigcup_{j=1}^{m} C_{i,j}. \)

Hence, \( C_i \in \Sigma_1. \) Therefore the atoms of \( \gamma^L \) are also in \( \Sigma_1. \) Since \( f \) is onto, the definition of \( C'_i \) implies

\[ C'_i \cap A_p = \bigcup \{ C'_i \cap C'_j \mid f(j) = p \}. \]

So \( C'_i \cap A_p \) is in \( \Sigma_1 \) for all \( i, p. \) Now \( C_i \cap A_p = C_{i,p} \cup (C'_i \cap A_p). \) So \( C_i \cap A_p \in \Sigma_1 \) for all \( i, p. \) Since

\[ A_p = \bigcup_{i=1}^{m} C_i \cap A_p, \]

\( A_p \in \Sigma_1. \) Since \( p \) is arbitrary, this proves the claim. Thus \( \gamma_1 \in \mathcal{P}_{eq}(\alpha). \)

We claim that \( \mu(C'_i \triangle C_i) \leq 3\epsilon \) for all \( i. \) By definition,

\[ C'_i \triangle C_i = C_i - C'_i \subseteq \bigcup_{j=1}^{m_L} C'_j - A_{f(j)}. \]

For each \( j, \)

\[ C'_j - A_{f(j)} \subseteq (C'_j - B'_j) \cup (B'_j - A_{f(j)}). \]

Thus,

\[ C'_i \triangle C_i \subseteq \bigcup_{j=1}^{m_L} (C'_j - B'_j) \cup \bigcup_{j=1}^{r} (B'_j - A_{f(j)}) \cup \bigcup_{j>r} (B'_j - A_{f(j)}). \] \hspace{1cm} (3)

If \( j \leq r, \) then by definition of \( r, \)

\[ \frac{\mu(B'_j \cap A_{f(j)})}{\mu(B'_j)} \geq 1 - \epsilon. \]

This implies

\[ \mu(B'_j - A_{f(j)}) \leq \epsilon \mu(B'_j). \]
Thus

\[ \mu \left( \bigcup_{j=1}^{r} B_j^L - A_{f(j)}^L \right) \leq \sum_{j} \epsilon \mu(B_j^L) \leq \epsilon. \quad (4) \]

Equations 3, 2, 4 and 1 imply the claim.

Since \( \delta < \epsilon \) and \( \mu(C_i \Delta B_i) < \delta \) for all \( i \), the above claim implies that \( \mu(C'_i \Delta B_i) \leq 4\epsilon \) for all \( i \). Thus we have shown that for every \( \epsilon > 0 \), there exists a partition \( \gamma_1 = \{C'_1, \ldots, C'_m, \ldots\} \), combinatorially equivalent to \( \alpha \), containing at most \( m + m^2 \) partition elements and such that \( \mu(C'_i \Delta B_i) < 4\epsilon \) for \( i = 1 \ldots m \). This implies that \( \beta \) is in the closure of \( \mathcal{P}_{eq}(\alpha) \). Since \( \beta \) is arbitrary this implies the theorem.

4 Splittings

In this section, \( G \) can be any finitely generated group with finite symmetric generating set \( S \). Let \((X, \mu)\) be a standard probability space on which \( G \) acts by measure-preserving transformations.

Definition 9. Let \( \alpha \) be a partition. A simple splitting of \( \alpha \) is a partition \( \sigma \) of the form \( \sigma = \alpha \lor s\beta \) where \( s \in S \) and \( \beta \) is a coarsening of \( \alpha \).

A splitting of \( \alpha \) is any partition \( \sigma \) that can be obtained from \( \alpha \) by a sequence of simple splittings. In other words, there exist partitions \( \alpha_0, \alpha_1, \ldots, \alpha_m \) such that \( \alpha_0 = \alpha, \alpha_m = \sigma \) and \( \alpha_{i+1} \) is a simple splitting of \( \alpha_i \) for all \( 1 \leq i < m \).

If \( \sigma \) is a splitting of \( \alpha \) then \( \alpha \) and \( \sigma \) are combinatorially equivalent. The splitting concept originated from Williams’ work [Wi73] in symbolic dynamics.

Definition 10. The Cayley graph \( \Gamma \) of \((G, S)\) is defined as follows. The vertex set of \( \Gamma \) is \( G \). For every \( s \in S \) and every \( g \in G \) there is a directed edge from \( g \) to \( gs \) labeled \( s \). There are no other edges.

The induced subgraph of a subset \( F \subset G \) is the largest subgraph of \( \Gamma \) with vertex set \( F \). A subset \( F \subset G \) is connected if its induced subgraph in \( \Gamma \) is connected.

Lemma 4.1. If \( \alpha, \beta \in \mathcal{P}, \alpha \) refines \( \beta \) and \( F \subset G \) is finite, connected and contains the identity element \( e \) then

\[ \alpha \lor \bigvee_{f \in F^{-1}} f\beta \]

is a splitting of \( \alpha \).

Proof. We prove this by induction on \( |F| \). If \( |F| = 1 \) then \( F = \{e\} \) and the statement is trivial. Let \( f_0 \in F - \{e\} \) be such that \( F_1 = F - \{f_0\} \) is connected. To see that such an \( f_0 \) exists, choose a spanning tree for the induced subgraph of \( F \). Let \( f_0 \) be any leaf of this tree that is not equal to \( e \).
By induction, $\alpha_1 := \alpha \lor \bigvee_{f \in F_1^{-1}} f \beta$ is a splitting of $\alpha$. Since $F$ is connected, there exists an element $f_1 \in F_1$ and an element $s_1 \in S$ such that $f_1 s_1 = f_0$. Since $f_1 \in F_1$, $\alpha_1$ refines $(f_1^{-1} \beta)$. Thus
\[
\alpha \lor \bigvee_{f \in F^{-1}} f \beta = \alpha_1 \lor f_0^{-1} \beta = \alpha_1 \lor s_1^{-1}(f_1^{-1} \beta)
\]
is a splitting of $\alpha$.

**Proposition 4.2.** Let $\alpha, \beta$ be two combinatorially equivalent generating partitions. Then there is an $n \geq 0$ such that
\[
\alpha^n = \bigvee_{g \in B(e,n)} g \alpha
\]
is a splitting of $\beta$. Here $B(e,n)$ is the ball of radius $n$ centered at the identity element in $G$ with respect to the word metric induced by $S$. Of course, $\alpha^n$ is also a splitting of $\alpha$.

This proposition is a variation of a result that is well-known in the case $G = \mathbb{Z}$ in the context of subshifts of finite-type. For example, see [LM95, theorem 7.1.2, page 218]. It was first proven in [Wi73].

**Proof.** Let $L, M \subset G$ be finite sets such that $\alpha \leq \beta^L$ and $\beta \leq \alpha^M$. Let $l, m \in \mathbb{N}$ be such that $L \subset B(e, l)$ and $M \subset B(e, m)$. So $\alpha \leq \beta^l$ and $\beta \leq \alpha^m$. Since balls are connected and $\alpha \leq \beta^l$, the previous lemma implies $\beta^l \lor \alpha^m$ is a splitting of $\beta$, and therefore, is a splitting of $\beta$. But $\beta^l \lor \alpha^m = (\beta \lor \alpha)^l = \alpha^m$.

**Theorem 4.3.** Let $\Phi : \mathcal{P} \to \mathbb{R}$ be any continuous function. Suppose that $\Phi$ is monotone decreasing under splittings; i.e., if $\sigma$ is a splitting of $\alpha$ then $\Phi(\sigma) \leq \Phi(\alpha)$. Define $\phi : \mathcal{P} \to \mathbb{R}$ by
\[
\phi(\alpha) = \lim_{n \to -\infty} \Phi(\alpha^n) = \inf_n \Phi(\alpha^n).
\]

Then, for any two finite generating partitions $\alpha_1$ and $\alpha_2$, $\phi(\alpha_1) = \phi(\alpha_2)$. So we may define $\phi(G, X, \mu) = \phi(\alpha)$ for any finite generating partition $\alpha$. The number $\phi(G, X, \mu)$ is a measure-conjugacy invariant.

**Proof.** Let $\alpha$ and $\beta$ be two combinatorially equivalent finite partitions. We claim that $\phi(\alpha) = \phi(\beta)$. To see this, suppose, for a contradiction, that $\phi(\alpha) < \phi(\beta)$. Then there exists an $n \geq 0$ such that $\Phi(\alpha^n) < \phi(\beta)$. But by the previous proposition, there is an $m \geq 0$ such that $\beta^m$ is a splitting of $\alpha^n$ which implies $\Phi(\alpha^n) \geq \Phi(\beta^m) \geq \phi(\beta)$, a contradiction. So $\phi(\alpha) = \phi(\beta)$.

For $n \geq 0$ and $\alpha \in \mathcal{P}$, let $\Phi_n(\alpha) = \Phi(\alpha^n)$. Since $\Phi$ is continuous and the map $\alpha \mapsto \alpha^n$ is also continuous, it follows that $\Phi_n$ is continuous. Since $\phi(\alpha) = \inf_n \Phi_n(\alpha)$, it follows that $\phi$ is upper semi-continuous, i.e., if $\{\beta_n\}$ is a sequence of partitions converging to $\alpha$ then $\limsup_n \phi(\beta_n) \leq \phi(\alpha)$.

Now let $\alpha, \beta$ be two finite generating partitions. By theorem 4.3, there exist finite partitions $\{\beta_n\}_{n=1}^\infty$ combinatorially equivalent to $\beta$ such that $\{\beta_n\}_{n=1}^\infty$ converges to $\alpha$. So $\phi(\beta) = \limsup_n \phi(\beta_n) \leq \phi(\alpha)$. Similarly, $\phi(\alpha) \leq \phi(\beta)$. So $\phi(\alpha) = \phi(\beta)$.
5 The $f$-invariant

In this section, $G = \langle s_1, \ldots, s_r \rangle$. Let $(X, \mu)$ be a standard probability space on which $G$ acts by measure-preserving transformations and let $S = \{s_1^\pm, \ldots, s_r^\pm\}$. Note $|S| = 2r$. Let $F: \mathcal{P} \to \mathbb{R}$ be defined as in the introduction.

Proposition 5.1. Let $\alpha \in \mathcal{P}$. If $\sigma$ is a splitting of $\alpha$ then $F(\sigma) \leq F(\alpha)$.

Proof. By induction, it suffices to prove the proposition in the special case in which $\sigma$ is a simple splitting of $\alpha$. So let $\sigma = \alpha \lor t\beta$ for some $t \in S$ and coarsening $\beta$ of $\alpha$. For any $s \in S$,

\[
H(\sigma \lor s\sigma) = H(\alpha \lor s\alpha) + H(\sigma \lor s\alpha | \alpha \lor s\alpha) \\
= H(\alpha \lor s\alpha) + H(s\alpha | \alpha \lor s\alpha) + H(\sigma | \alpha \lor s\alpha | s\alpha) \\
\leq H(\alpha \lor s\alpha) + H(\sigma | \alpha \lor s^{-1} \alpha) + H(\sigma | \alpha \lor s\alpha).
\]

The last inequality occurs because $\mu$ is $G$-invariant, so $H(s\alpha | \alpha \lor s\alpha) = H(\sigma | \alpha \lor s^{-1} \alpha)$.

Since $H(\sigma) = H(\alpha) + H(\sigma | \alpha)$, the above implies

\[
F(\sigma) \leq (1 - 2r)(H(\alpha) + H(\sigma | \alpha)) + \sum_{i=1}^{r} H(\alpha \lor s\alpha) + H(\sigma | \alpha \lor s^{-1} \alpha) + H(\sigma | \alpha \lor s\alpha).
\]

Since $\sigma \leq \alpha \lor t\alpha$, $H(\sigma | \alpha \lor t\alpha) = 0$. Hence

\[
F(\sigma) - F(\alpha) \leq (1 - 2r)H(\sigma | \alpha) + \sum_{s \in S \setminus \{t\}} H(\sigma | \alpha \lor s\alpha) \\
= \sum_{s \in S \setminus \{t\}} \left( H(\sigma | \alpha \lor s\alpha) - H(\sigma | \alpha) \right) \leq 0.
\]

\[\square\]

Theorem 4.3 now follows from the proposition above and theorem 4.3.

Definition 11. Let $K$ be a finite set and $\kappa$ a probability measure on $K$. Let $K^G$ be the product space with the product measure $\kappa^G$. The system $(G, K^G, \kappa^G)$ is called the Bernoulli shift over $G$ with base measure $\kappa$.

Let $A_k = \{x \in K^G | x(e) = k\}$ where $e$ denotes the identity element in $G$. Then $\alpha = \{A_k | k \in K\}$ is the Bernoulli partition associated to $K$. It is generating and $H(\kappa) = H(\alpha)$, by definition.

Theorem 5.2. Let $G = \langle s_1, \ldots, s_r \rangle$ be the free group of rank $r$. Let $K$ be a finite set and $\kappa$ a probability measure on $K$. Then

\[
f(G, K^G, \kappa^G) = H(\kappa).
\]
Proof. Let \( \alpha \) be the Bernoulli partition associated to \( K \). Let \( g_1, \ldots, g_n \) be \( n \) distinct elements of \( G \). It follows from the Bernoulli condition that the collection \( \{g_i\alpha\}_{i=1}^n \) of partitions is independent. This means that if \( j : \{1, \ldots, n\} \to K \) is any function then

\[
\kappa^G\left( \bigcap_{i=1}^n g_iA_{j(i)} \right) = \prod_{i=1}^n \kappa^G(A_{j(i)}).
\]

It is well-known that this implies

\[
H\left( \bigvee_{i=1}^n g_i\alpha \right) = \sum_{i=1}^n H(g_i\alpha) = nH(\alpha).
\]

See, for example, [Gl03, prop. 14.19, page 257]. So for any \( k \geq 1 \),

\[
F(\alpha^k) = \left( \frac{1}{2} \sum_{s \in S} H(\alpha^k \vee s\alpha^k) \right) - (|S| - 1)H(\alpha^k)
\]

\[
= \left( \frac{1}{2} \sum_{s \in S} |B(e, k) \cup B(s, k)|H(\alpha) \right) - (|S| - 1)|B(e, k)|H(\alpha).
\]

Suppose \( r > 1 \). Then, since \( G = \langle s_1, \ldots, s_r \rangle \) is free, it is a short exercise to compute:

\[
|B(e, k)| = 1 + |S|\left( \frac{|S| - 1)^k - 1}{|S| - 2} \right)
\]

\[
|B(e, k) \cup B(s, k)| = 2\left( \frac{(|S| - 1)^k - 1}{|S| - 2} \right)
\]

for all \( s \in S \). Thus,

\[
F(\alpha^k) = H(\alpha)\left( \frac{|S|(|S| - 1)^k - 1}{|S| - 2} - (|S| - 1) - (|S| - 1)|S|\left( \frac{|S| - 1)^k - 1}{|S| - 2} \right) \right)
\]

\[
= H(\alpha).
\]

If \( r = 1 \) then \( |B(e, k)| = 2k + 1 \) and \( |B(e, k) \cup B(s, k)| = 2k + 2 \). So it follows in a similar way that \( F(\alpha^k) = H(\alpha) \). So \( f(G, X, \mu) = \lim_{k \to \infty} F(\alpha^k) = H(\alpha) = H(\kappa) \).

Proof of theorem. According to Stepin’s theorem [St75], if \( (K_1, \kappa_1), (K_2, \kappa_2) \) are standard Borel probability spaces with \( H(\kappa_1) = H(\kappa_2) \) then \( (G, K_1^G, \kappa_1^G) \) is measurably conjugate to \( (G, K_2^G, \kappa_2^G) \).

Now suppose \( (K_1, \kappa_1), (K_2, \kappa_2) \) are Borel probability spaces such that \( (G, K_1^G, \kappa_1^G) \) is measurably conjugate to \( (G, K_2^G, \kappa_2^G) \). Let \( (L_1, \lambda_1), (L_2, \lambda_2) \) be probability spaces with \( |L_1| + |L_2| < \infty \) and \( H(\lambda_i) = H(\kappa_i) \) for \( i = 1, 2 \). By Stepin’s theorem, \( (G, L_1^G, \lambda_1^G) \) is measurably conjugate to \( (G, K_1^G, \kappa_1^G) \). By the above theorem, \( f(G, L_1^G, \lambda_1^G) = H(\lambda_1) \). Since \( f \) is a measure-conjugacy invariant, \( H(\kappa_1) = H(\kappa_2) \).
