BOUNDS FOR THE SUM OF DISTANCES OF SPHERICAL SETS OF SMALL SIZE

ALEXANDER BARG1, PETER BOYVALENKOV2, MAYA STOYANOVA3

ABSTRACT. We derive upper and lower bounds on the sum of distances of a spherical code of size $N$ in $n$ dimensions when $N = \Theta(n^\alpha)$, $0 < \alpha \leq 2$. The bounds are derived by specializing recent general, universal bounds on energy of spherical sets. We discuss asymptotic behavior of our bounds along with several examples of codes whose sum of distances closely follows the upper bound.

1. Introduction: Sum of distances and related problems

1.1. Problem statement and overview of results. Let $C_N = \{z_1, \ldots, z_N\}$ be a set of $N$ points (code) on the unit sphere $S^{n-1}$ in $\mathbb{R}^n$. Denote by $\tau_n(C_N) = \sum_{i,j=1}^N |z_i - z_j|$ the sum of pairwise distances between the points in $C_N$ and let $\tau(n, N) = \sup_{C_N} \tau_n(C_N)$ be the largest attainable sum of distances over all sets of cardinality $N$. The problem of estimating $\tau(n, N)$ was introduced by Fejes Tóth [29] and it has been studied in a large number of follow-up papers, [32, 10]. The main body of results in the literature are concerned with the asymptotic regime of fixed $n$ and $N \to \infty$. In particular, it is known that

$$cN^{1-\frac{1}{n-1}} \leq W(S^{n-1})N^2 - \tau(n, N) \leq C N^{1-\frac{1}{n-1}},$$

where $W(S^{n-1}) = \int |x - y|d\sigma_n(x)d\sigma_n(y)$ is the average distance on the sphere, $\sigma_n$ is the normalized (surface area) measure on the sphere, and $c, C$ are some positive constants that depend only on $n$. The upper bound in (1) is due to Alexander [1] for $n = 3$ and Stolarsky [48] for higher dimensions, and the lower bound was proved by Beck [6]. Kuźnjaurs and Saff [37] extended these results to bounds on the $s$-Riesz energy of spherical sets for all $s > 0$, and Brauchart et al. [17] computed next terms of the asymptotics; see also Ch. 6 in a comprehensive monograph by Borodachov et al. [11] for a recent overview.

In this paper we adopt a different view, allowing both the dimension $n$ and the cardinality $N$ to increase in a certain related way. The main emphasis of this work is on obtaining explicit lower and upper bounds on the sum of distances of a spherical set $C_N$ for $N \sim \delta n^\alpha$, for certain $\delta$ and $0 < \alpha \leq 2$. Upper bounds apply uniformly for all spherical sets, while to derive lower bounds we need to assume that the minimum pairwise distance is bounded from below (otherwise the sum of distances can be made arbitrarily small). If the minimum distance is large, then the neighbors of a point are naturally placed on or near the orthogonal subsphere (the "equator"), and the distance to them is about $\sqrt{2}$. This suggests that the main term in the asymptotic expression for the sum of distances is $\sqrt{2}N^2$, and it is easy to obtain a bound of the form $\tau(n, N) \leq \sqrt{2}N^2(1 + o(1))$, as shown below in Sec. 1.2.

Our main results are related to refinements of this claim. Using linear programming, we derive lower and upper bounds for the sum of distances of codes of small size. For a number of code families, the sum of distances behaves as $\sqrt{2}N^2$, and the bound is asymptotically tight. We compute lower-order terms in a number of examples, including codes obtained from equiangular line sets, spherical embeddings of strongly regular graphs (two-distance tight frames), and spherical embeddings of some classes of small-size binary...
codes. Numerical calculations, some of which we include, confirm that the sum of distances of these codes follows closely the upper bound.

1.2. Sum of distances and Stolarsky’s invariance. The sum of distances in a spherical code enjoys several links with other problems in geometry of spherical sets. One of them is related to the theory of uniform distributions on the sphere. A sequence of spherical sets \( \{C_N\}_N \) is called asymptotically uniformly distributed if for every closed set \( A \subset S^{n-1} \)

\[
\lim_{N \to \infty} \frac{|C_N \cap A|}{N} = \sigma(A).
\]

To quantify the proximity of a sequence of sets \( C_N \) to the uniform distribution on \( S^{n-1} \), define the quadratic discrepancy\(^1\) of \( C_N \):

\[
D_{L^2}^{\text{q}}(C_N) := \int_{-1}^{1} \int_{S^{n-1}} \left| \frac{1}{N} \sum_{j=1}^{N} \mathbb{I}_{C(x,t)}(z_j) - \sigma_n(C(x,t)) \right|^2 d\sigma_n(x) dt,
\]

where \( C(x,t) = \{ y \in S^{n-1} : \langle x, y \rangle \geq t \} \) is a spherical cap of radius \( \arccos t \) centered at \( x \). A classic result states that a sequence of sets \( C_N \) is asymptotically uniformly distributed if and only if \( \lim_{N \to \infty} D_{L^2}^{\text{q}}(C_N) = 0 \); see, e.g., [11, Theorem 6.1.5]. A fundamental relation between \( \tau_n(C_N) \) and \( D_{L^2}^{\text{q}}(C_N) \) states that the sum of these two quantities is a constant that depends only on \( N \) and \( n \). Namely,

\[
c_n D_{L^2}^{\text{q}}(C_N) = W(S^{n-1}) - \frac{1}{N^2} \tau_n(C_N),
\]

where \( c_n = (n - 1) \sqrt{\pi} \Gamma((n - 1)/2) / \Gamma(n/2) \) is a universal constant that depends only on the dimension of the sphere. This relation was proved by Stolarsky [48] and is now known as Stolarsky’s invariance principle.

The average distance on the sphere is given by \( \frac{1}{2} \int_0^\pi 2 \sin(\theta/2) \sin^{n-1} \theta d\theta / \int_0^\pi \sin^{n-1} \theta d\theta \), which evaluates to

\[
W(S^{n-1}) = \frac{2^{n-1} \Gamma(n/2)^2}{\sqrt{\pi} \Gamma(n - 1/2)} = \sqrt{2} - \frac{1}{4\sqrt{2n}} + O(n^{-2}).
\]

Since \( D_{L^2}^{\text{q}}(C_N) \geq 0 \), the following bound is immediate: for any code \( C_N \subset S^{n-1} \)

\[
\tau_n(C_N) \leq N^2 \left( \sqrt{2} - \frac{1}{4\sqrt{2n}} + O(n^{-2}) \right).
\]

This inequality in effect states a well-known fact that the average of a radial negative-definite kernel, over a subset of the sphere is at most the average over the entire sphere. It also forms a very particular case of a recent general result in [14, Theorem 3.1].

Remarks

1. On account of (3), the problem of maximizing the sum of distances is equivalent to minimizing the quadratic discrepancy, i.e., the sum of distances serves as a proxy for uniformity: a set of \( N \) points on the sphere is “more uniform” if the sum of pairwise distances is large for its size.

2. Sequences \( \{C_N\}_N \) with average distance \( \sqrt{2}(1 + o(1)) \) are asymptotically uniformly distributed. As we have already pointed out, many sequences of codes satisfy this condition; moreover, as shown below, spherical codes obtained from the binary Kerdock and dual BCH codes match the second term in (4), implying a faster rate of convergence to the limit.

3. Extensions and generalizations of Stolarsky’s invariance were proposed in recent works [18, 9, 8, 46, 47, 4]. In particular, [4] studied quadratic discrepancy of binary codes, deriving explicit expressions as well as some bounds. Below in Sec. 4, we point out that this problem is closely related to the sum-of-distances problem in the spherical case, and translate our results on bounds to the binary case. This link also motivates

\(^1\)More precisely, the discrepancy is defined as \( (D_{L^2}^{\text{q}}(C_N))^{1/2} \), and it is called the spherical cap discrepancy, as there are also other types of discrepancy on the sphere.
studying the asymptotic regime of \( n \to \infty \) for spherical codes because this is the only possible asymptotics in the binary space.

1.3. Details of our approach. Viewing the distance \( \|x - y\| \) as a two-point potential on the sphere, we can relate the problem of estimating \( \tau(n, N) \) to the search for spherical configurations with the minimum potential energy. References [37], [17], [11], and many others adopt this point of view, considering the energy minimization for general classes of potential functions on the sphere. A line of works on energy minimization, initiated by Yudin [52, 36] and developed by Cohn and Kumar [24], uses the linear programming bounds on codes to derive results about optimality as well as lower bounds on the energy of spherical codes. Extending the approach of earlier works by Yudin and Levenshtein [39, 41], the authors of [24] proved optimality of several known spherical codes for all absolutely monotone potentials\(^2\) and called such codes universally optimal. In particular, denoting \( t = t(x, y) = x \cdot y \), we immediately observe that the potential \( L(t) = -\|x - y\| = -\sqrt{2(1 - t)} \) fits in this scheme since \( 2 + L(t) \) is absolutely monotone, and thus all the known universally optimal codes are maximizers of the sum of distances.

While the results of [24] apply to specific spherical codes, a suite of universal bounds on the potential energy was derived in recent papers of Boyvalenkov, Dragnev, Hardin, Saff, and Stoyanova [13, 14, 15, 16]. While the bounds can be written in a general form relying on the Levenshtein formalism, explicit expressions are difficult to come by. We derive an explicit form of the first few bounds in the Levenshtein hierarchy and evaluate them for the families of spherical codes mentioned above, limiting ourselves to the potential \( L(t) \). Our approach can be summarized as follows. Given an absolutely monotone potential \( h \), define the minimum \( h \)-energy over all spherical sets of size \( N \)

\[
E_h(n, N) := \inf_{\mathcal{C}} E_h(\mathcal{C}_N),
\]

where \( E_h(\mathcal{C}_N) = \sum_{i,j=1}^N h(z_i \cdot z_j) \). This quantity is bounded from below as follows:

\[
E_h(n, N) \geq N^2 \sum_{i=0}^{k-1+\varepsilon} \rho_i h(\alpha_i),
\]

where the positive integer \( k \), the value \( \varepsilon \in \{0, 1\} \), and the real parameters \( (\rho_i, \alpha_i), i = 0, 1, \ldots, k - 1 + \varepsilon \), are functions of \( N \) and \( n \) as explained in [14] and in Section 5 below. The bound (5) was called a universal lower bound (ULB) in [14]. For given \( k \) and \( \varepsilon \) we obtain a degree-\( m \) bound, \( m = 2k - 1 + \varepsilon \), where the term “degree” refers to the degree of the polynomial used in the corresponding linear programming problem. The bound of degree \( m \) applies to the values of code cardinality in the segment \( D^*(n, m) := N < D^*(n, m + 1) \), where \( D^*(n, m) := \binom{n+k-2+\varepsilon}{n-1} + \binom{n+k-2}{n-2} \) comes from the Delsarte, Goethals and Seidel’s bound [26] for the minimum possible cardinality of spherical \( \tau \)-designs on \( S^{n-1} \). The first few segments are as follows:

\[
[2, n), [n + 1, 2n), [2n, n(n + 3)/2), [n(n + 3)/2, n(n + 1)), [n(n + 1), n(n^2 + 6n + 5)/6).
\]

The results of [14] also imply the optimal choice of the polynomial, so the bounds we obtain cannot be improved by choosing a different polynomial of degree \( \leq m \). The bound (5) will be expressed below in terms of \( n \) and \( N \) for \( m = 1, 2, \) and 3.

Similarly, it is possible to bound the \( h \)-energy from above under the condition that the maximum inner product \( s \) between distinct vectors in \( \mathcal{C}_N \) is fixed, or, allowing \( n \) and \( N \) to grow, satisfies the condition \( \lim_{n \to \infty} s < 1 \). Note that if \( n \) increases then so does \( N \), and the relation between them affects the asymptotic expressions. Consider the quantity

\[
E_h(n, N, s) := \sup \{ E_h(\mathcal{C}_N) : x \cdot y \leq s, x, y \in \mathcal{C}_N, x \neq y \},
\]

\(^2\)A potential \( h(t) : [-1, 1] \to \mathbb{R} \) is called absolutely monotone if for every \( n \geq 0 \) the derivative \( h^{(n)}(t) \) exists and is nonnegative for all \( t \).
which is applicable, in particular, for all $p$ where this time the parameters hold true: on the sum of distances obtained from the general results in the cited works, deferring the proof to Sec. although obtaining explicit expressions is not immediate. In this section we list the lower and upper bounds i.e., the supremum of $h$-energy of spherical codes of fixed dimension, cardinality, and minimum separation. Universal upper bounds (UUBs) for $E_h(n, N, s)$ were derived in [16]. To this end, the linear programming functional $f_0[\mathcal{E}] - f(1)$ is minimized on the set of polynomials

$$\left\{ f(t) = \sum_{i=0}^{\deg(f)} f_i P_i^{(n)}(t) : f(t) \geq h(t), t \in [-1, s]; f_i \leq 0, i \geq 1 \right\},$$

where $P_i^{(n)}(t)$ are the Gegenbauer polynomials (normalized by $P_i^{(n)}(1) = 1$). In [16], the authors use a specific choice of the polynomials $f(t)$ for fixed $n$, $N$, and $s$ as explained in Section 5. This leads to the bound

$$E_h(n, N, s) \leq \left( \frac{N}{N_1} - 1 \right) N f(1) + N^2 \sum_{i=0}^{k-1+\varepsilon} \rho_i h(\alpha_i),$$

(6)

where this time the parameters $(\rho_i, \alpha_i)$ are functions of the dimension $n$ and the minimum separation $s$, and $N_1 = L_m(n, s)$, $m = 2k - 1 + \varepsilon$, is the corresponding Levenshtein bound (see Sec. 5 for additional details). The bound (6) will be expressed below in terms of $n$, $N$, and $s$ for $m = 1$, 2, and 3.

While in this paper our focus is on codes of small size, a recent general result in [15] (Theorem 7 and Corollary 1) implies the following asymptotic bound for the sum of distances:

$$\tau_n(\mathcal{E}_N) \leq \sqrt{2N^2} - \frac{N^{3/2}}{4\sqrt{2}}(1 + o(1)),$$

which is applicable, in particular, for all $N$ such that $D^*(n, 2l) \leq N < D^*(n, 2l + 1), l \geq 1$.

2. Bounds

General bounds on energy of spherical codes obtained earlier in [14] and [16] apply to the sum of distances, although obtaining explicit expressions is not immediate. In this section we list the lower and upper bounds on the sum of distances obtained from the general results in the cited works, deferring the proof to Sec. 5. We limit ourselves to the first three bounds in the sequence of lower and upper bounds, noting that even in this case, the resulting expressions are unusually cumbersome.

2.1. Upper bounds. The following bounds on the maximum sum of distances of a spherical code in $n$ dimensions hold true:

$$\tau(n, N) \leq \begin{cases} \tau_1(n, N) := N \sqrt{2N(N - 1)} & \text{for } 2 \leq N \leq n + 1, \\ \tau_2(n, N) := \frac{N \left( 2N(N - n - 1) + (N - 2)\sqrt{2nN(n - 1)(N - 2)} \right)}{Nn + N - 4n} & \text{for } n + 1 \leq N \leq 2n, \\ \tau_3(n, N) := \frac{\sqrt{2N(nA_1 + 2(N - n - 1)^2B_1)}}{n^2(n - 1)^2 + 4n(N - n - 1)(N - 2n)} & \text{for } 2n \leq N \leq n(n + 3)/2, \end{cases}$$

(7) (8) (9)

where the first bound applies for $2 \leq N \leq n + 1$, the second for $n + 1 \leq N \leq 2n$, the third for $2n \leq N \leq n(n + 3)/2$, and where

$$A_1 = Nn^3 + (2N - 1)n^2 - (N - 1)(7N - 2)n + (N - 1)^2(2N + 3),$$

(10)

$$B_1 = \sqrt{n(n - 1)N(N - n - 1)}.$$

(11)
Bound (7) is attained by the simplex code, bound (8) is attained by the biorthogonal code, and bound (9) is attained by all codes that meet the 3rd Levenshtein bound\footnote{All the known codes attaining Levenshtein bounds are listed in \cite[Table 9.1]{table91}. There are two infinite series of codes as well as three sporadic examples that meet the 3rd bound. Some of these codes, originating from strongly regular graphs, were discovered in \cite{stronglyregular} which established a condition for them to meet the 3rd Levenshtein bound; see \cite{table91} for the details of this connection.} \cite[p.620]{table91}. Due to (3), these codes have the smallest quadratic discrepancy among all codes of their size.

In the asymptotics of \( n \to \infty \) bounds (7) and (8) yield

\[
\tau_1(n, N) = \sqrt{2}N^2 - \frac{N}{\sqrt{2}} + O(1) \quad \text{if } N \sim \delta n, \ 0 < \delta \leq 1,
\]

\[
\tau_2(n, N) = \sqrt{2}N^2 - 2\left(1 - \delta - \frac{1 - 3\delta/\sqrt{2}}{\sqrt{2}}\right)N + O(1) \quad \text{if } N \sim \delta n, \ 1 \leq \delta \leq 2.
\]

Note that the bound (13) is slightly tighter than (12) because of a larger second term, which is greater than \( \frac{1}{\sqrt{2}} \) for all \( \delta > 1 \). The bound (13) is also uniformly better than (4) for all \( N = \delta n, \delta \in [1, 2] \).

The bound (9) is valid for \( N \leq n(n + 3)/2 \). Writing \( N \sim \delta n^\alpha \), we note that its asymptotic behavior depends on \( \alpha \). For instance, for \( N = \delta n^2 \) we obtain

\[
\tau_3(n, N) = \sqrt{2}N^2 - \frac{\sqrt{2\pi}}{8}N^{3/2} + O(N).
\]

Here the order of the second term of the asymptotics coincides with the bound obtained from the average distance (4) while the constant factor is better for all \( \delta > 1 \).

2.2. Lower bounds. Let \( C_N \) be a spherical code in \( n \) dimensions, and assume that the minimum distance between distinct points \( z_i, z_j \in C_N \) is bounded from below, i.e., that \( z_i \cdot z_j \leq s \) for some \( s \in [-1, 1] \). Denote by \( \tau_n(N, s) = \inf_{C_N} \tau_n(C_N) \) the smallest possible sum of distances for such codes. We have

\[
\tau_n(N, s) \geq \tau^{(i)}(n, N, s), \ i = 1, 2, 3,
\]

where the bound

\[
\tau^{(1)}(n, N, s) = N(N - 1)\sqrt{2(1 - s)},
\]

is applicable in (15) for \( N \in [2, n + 1] \) and \( s \in [-1/(N - 1), -1/n] \), the bound

\[
\tau^{(2)}(n, N, s) = \frac{N \left(2N(1 - ns^2) - 2n(1 - s^2) + (n - 1)\sqrt{2(1 - s)}\right)}{n(1 - s^2)},
\]

is applicable for \( n + 1 \leq N \leq 2n \) and \( s \in \left[\frac{N - 2n}{n(n - 2)}, 0\right] \), and the bound

\[
\tau^{(3)}(n, N, s) = \frac{N \left( (1 - s)(1 + ns)A_4 + B_4\sqrt{(1 - s)B_5} \right) - 2N(1 + 2s + ns^2)C_4\sqrt{A_5}}{n(1 - s)(1 + 2s + ns^2)^2C_4\sqrt{2B_5}},
\]

is applicable for \( 2n \leq N \leq n(n + 3)/2 \) and

\[
s \in \left[\frac{\sqrt{n^2(n - 1)^2 + 4n(N - n - 1)(N - 2n)} - n(n - 1)}{2n(N - n - 1)}, \frac{\sqrt{n + 3} - 1}{n + 2}\right].
\]
where the notation in (18) is as follows:

\[A_2 = (1 + ns)^5(1 - s) + (n - 1)^2((n + 1)s + 2),\]
\[B_2 = (n - 1)\sqrt{(1 - s)(1 + ns)((n + 1)s + 2)}\]
\[A_4 = n(n + 2)(n + 3)s^4 + 2(3n^2 + 13n + 8)s^3 + 2(n^2 + 12n + 23)s^2 + 2(2n^2 + 5n + 17)s + 9n + 3,\]
\[B_4 = 2(n - 1)((n + 1)s + 2)((n - 2)s^2 - 2ns - 1),\]
\[C_4 = 2n(n + 2)s^3 - (n^2 - 5n - 2)s^2 - 6ns - n - 5,\]
\[A_5 = N(1 - ns^2) - n(1 - s)((n + 1)s + 2),\]
\[B_5 = \frac{(n + 1)s + 2}{1 + ns},\]
\[A_6 = \frac{(1 - s)(A_2 + 2(1 + ns)^2B_2)}{1 + ns}.\]  

(20)

Remarks.

1. Note that expression (16) yields a trivial bound on the sum of distances, assuming that every pair of code points is at distance \(\sqrt{2(1 - s)}\). It is included for completeness because it follows by optimizing the linear polynomial in the linear programming problem.

2. The bounds (16)–(18) are proved for \(s\) in the specified intervals above but are valid at least for slightly larger \(s\) (by continuity). For example, the bound (16) is valid for all \(s\). The lower limits for \(s\) are determined from the inequality \(N_1 \geq N\) and the upper limits are the same as for the Levenshtein bound \(L_m(n, s)\) (see in Sec. 5 for more details).

3. Using Mathematica, we can compute asymptotic behavior of \(\tau^{(3)}(n, N, s)\) for \(n \to \infty\). Since it depends on \(s\), we do not include general expressions, leaving this for the examples.

3. Examples of codes of small size

In this section we consider several families of spherical codes that attain the asymptotic extremum of the sum of distances. We focus on sets with a small number of distinct distances because the sum of distances is easier to compute, and because their cardinalities fit the range of the parameters used to derive the bounds in the previous section. We consider three types of objects, families of equiangular lines, strongly regular graphs, and binary codes. General introductions to their properties are found in [31, Ch.11], [19], and [43], respectively.

3.1. Equiangular lines. A family of \(M\) equiangular lines in \(\mathbb{R}^n\) with common inner product \(s\) defines a spherical code \(C_N\) with \(N = 2M\) vectors, each of which has inner product \(s\) with \(M - 1\) other vectors and 

\[\tau_n(C_N) = \sum_{i,j=1}^{N} \|z_i - z_j\| = N((M - 1)(\sqrt{2 - 2s} + \sqrt{2 + 2s}) + 2)\]
\[= N^2\sqrt{2(1 - s)} + O(N).\]  

(21)

For small \(s\) we can write \(\sqrt{1 - s} + \sqrt{1 + s} = 2 - \frac{s^2}{4} + O(s^4)\), so for \(M = \Theta(n^2)\) the sum of distances will be close to the value \(\sqrt{2}N^2\) given by the bound (14). Example 1 below illustrates this claim.

Examples.

1. Constructions with \(M = \Theta(n^2)\). There are several constructions of large-size sets of equiangular lines, starting with De Caen’s family [25]; see also [33]. In all these constructions \(s \to 0\), and thus the sum
of distances equals \( \tau_n(\mathcal{C}_N) = \sqrt{2}N^2(1 + o(1)) \), showing that such families yield asymptotically optimal spherical codes. For instance, De Caen’s family yields codes \( \mathcal{C}_N \) with the parameters

\[
n = 3 \cdot 2^{n-1} - 1, \quad N = \frac{4}{9}(n + 1)^2, \quad s = \frac{1}{2n^2}, \quad r \geq 1,
\]

and we find from (21) that

\[
\tau_n(\mathcal{C}_N) = \sqrt{2}N^2 - \frac{1}{4\sqrt{2}}N^{3/2} + O(N^{5/4}).
\]

At the same time, on account (14) and (18) any sequence of codes \( \mathcal{C}_N \) with \( N \sim \frac{1}{2}n^2 \) and \( s \sim \sqrt{\frac{3}{2n}} \) satisfies

\[
\sqrt{2}N^2 - \frac{1}{4\sqrt{2}}N^{7/4} - O(N^{3/2}) \leq \tau_n(\mathcal{C}_N) \leq \sqrt{2}N^2 - \frac{1}{6\sqrt{2}}N^{3/2} + O(N)
\]

(computations for the lower bound performed with Mathematica). We give examples of the bounds on the sum of distances of de Caen’s codes and of its true value for the first few values of \( r \).

| \( r \) | \( n \) | \( N \) | Upper bound \( \tau_3(n, N) \) | \( \tau_n(\mathcal{C}_N) \) | Lower bound \( \tau^{\text{asy}}_3(n, N, s) \) |
|---|---|---|---|---|---|
| 3 | 95 | 4096 | 2.369344 \times 10^4 | 2.368643 \times 10^4 | 2.341901 \times 10^4 |
| 4 | 383 | 65536 | 6.0719880 \times 10^9 | 6.071317 \times 10^9 | 6.036098 \times 10^9 |
| 5 | 1535 | 1048576 | 1.5548171 \times 10^{12} | 1.554763 \times 10^{12} | 1.550113 \times 10^{12} |
| 6 | 6143 | 16777216 | 3.9805762 \times 10^{15} | 3.980539 \times 10^{15} | 3.974643 \times 10^{15} |
| 7 | 24575 | 268435456 | 1.0190430 \times 10^{18} | 1.019041 \times 10^{18} | 1.018254 \times 10^{17} |

2. Below by \( M_s(n) \) we denote the maximum number of equiangular lines in \( n \) dimensions with inner product \( s \). It is known [38] that \( M_{1/3}(n) = 2(n - 1) \). Taking \( N = 4(n - 1) \) for a given \( n \), we obtain a spherical code \( \mathcal{C}_N \) with sum of distances equal to

\[
\tau_n(\mathcal{C}_N) = N((M - 1)(\sqrt{4/3} + \sqrt{8/3}) + 2) = N^2 \frac{1 + \sqrt{2}}{\sqrt{3}} (1 + o(1)).
\]

The constant factor in this expression is approximately 1.39. A more detailed calculation shows that

\[
\lim_{n \to \infty} \frac{\tau_n(\mathcal{C}_N)}{\tau_3(n, N)} = (\sqrt{6}(\sqrt{2} - 1))^{-1} \approx 0.9856.
\]

3. Further, by [44], \( M_{1/5}(n) = [3(n - 1)/2] \) for all sufficiently large \( n \). This set of lines yields a spherical code with sum of distances \( \tau_n(\mathcal{C}_N) = N^2((\sqrt{2} + \sqrt{3})/\sqrt{5})(1 + o(1)) \approx 1.407N^2 \), which is again very close to (14). It is not difficult to check that

\[
\lim_{n \to \infty} \frac{\tau_n(\mathcal{C}_N)}{\tau_3(n, N)} = (\sqrt{2} + \sqrt{3})/\sqrt{10} \approx 0.9949.
\]

4. A recent paper by Jiang and Polyanskii [34] shows that \( M_{1/(1 + 2\sqrt{2})}(n) = 3n/2 + O(1) \), yielding a spherical code of size \( N = 3n + O(1) \). For this code, the constant factor in (21) equals

\[
\frac{1}{\sqrt{2}}\left(\sqrt{1 - \frac{1}{1 + 2\sqrt{2}}} + \sqrt{1 + \frac{1}{1 + 2\sqrt{2}}} \right) \approx 1.40189.
\]

In the limit of \( n \to \infty \), the sum of distances satisfies \( \tau_n(\mathcal{C}_N)/\tau_3(n, N) \to 0.991 \).

More examples can be generated relying on constructions of equiangular line sets of size \( O(n^{3/2}) \) based on Taylor graphs and projective planes [38]. Recent additions to the literature include new upper bounds and exact asymptotics of the size of equiangular line sets with fixed inner product \( s [2, 30, 35] \).
3.2. **Strongly regular graphs and tight frames.** Here we consider the sum-of-distances function for spherical codes obtained from strongly regular graphs (SRG). A k-regular graph on \(v\) vertices is strongly regular if every pair of adjacent vertices has a common neighbor and every pair of nonadjacent vertices has \(c\) common neighbors. Below we use the notation \(\text{SRG}(v, k, a, c)\) when we need to mention the parameters explicitly.

The spectral structure of SRGs is well known; see for instance [21, p. 118], [23], or [28, Sec. 9.4] (the last two references highlight the relation between spherical codes and SRGs and more generally, association schemes). The adjacency matrix of an SRG has three eigenspaces that correspond to the eigenvalues \(k, r_1, r_2\). Let \(\Delta = (a - c)^2 + 4(k - c)\), then the eigenvalues other than \(k\) have the form
\[
 r_1 = \frac{1}{2} (a - c + \sqrt{\Delta}), \quad r_2 = \frac{1}{2} (a - c - \sqrt{\Delta}),
\]
and the dimensions of the corresponding eigenspaces are
\[
 n_{1,2} = \frac{1}{2} \left( v - 1 \pm \frac{(v - 1)(c - a) - 2k}{\sqrt{\Delta}} \right), \tag{22}\]
where we write \(n_{1,2}\) to refer to both eigenspaces at the same time.

Spherical embeddings of SRGs were introduced by Delsarte, Goethals, and Seidel [26], Example 9.1. To obtain a spherical code from an SRG, assign vectors of the standard basis of \(\mathbb{R}^v\) to the vertices, and then project the basis on an eigenspace of the graph. In particular, using the eigenspace \(W_{r_1}\) that corresponds to \(r_1\), we obtain a spherical code in \(\mathbb{R}^{n_{1,2}}\) with \(N = v\) points and inner products
\[
 s_1 = \frac{r_1}{k}, \quad s_2 = \frac{1 + r_1}{v - 1 - k}, \tag{23}\]
A similar procedure for \(r_2\) yields a spherical code in \(\mathbb{R}^{n_{2,2}}\) with \(v\) points and inner products
\[
 s_1 = -\frac{1 + r_2}{v - 1 - k}, \quad s_2 = \frac{r_2}{k}, \tag{24}\]
where in both cases \(s_1 \geq 0 > s_2\). We again reference [28, Sec. 9.4] for the details and [3] for a short proof.

The distribution of distances in the obtained spherical codes does not depend on the point \(z_i \in C_N\). If the code is obtained by projecting on \(W_{r_1}\), then the number of neighbors of a point with inner product \(r_1/k\) is \(k\), and if it is obtained by projecting on \(W_{r_2}\), then the number of neighbors of a point with inner product \(r_2/k\) is \(k\). Thus, in both cases, the number of neighbors with the remaining value of the inner product is \(N - k - 1\).

Combining (22), (23), and (24), we obtain

**Proposition 3.1.** Projecting an \(\text{SRG}(v, k, a, c)\) on the eigenspace \(W_\theta, \theta = r_1, r_2\) results in a spherical code in \(\mathbb{R}^{n_{1,2}}\) of size \(N = v\) whose sum of distances equals
\[
 \tau_{n_{1,2}}(C_N) = N \left( \sqrt{2k(k - \theta)} + \sqrt{2(N - 1 - k)(N + \theta - k)} \right), \tag{25}\]
where \(\theta = r_1\) or \(r_2\) as appropriate.

**Remark:** Families of spherical codes considered below attain sums of distances that can be written in the form \(\tau_n(C_N) = \sqrt{2N^2}(1 + o(1))\). A sufficient condition for this is that the eigenvalues are small compared to \(N\), as can be seen upon rewriting (25) in the form
\[
 \tau_n(C_N) = \sqrt{2N^2} \left( \sqrt{\frac{k(k - \theta)}{N^2}} + \sqrt{\frac{(N - k - 1)(N - k + \theta)}{N^2}} \right).
\]
As long as \(\theta/N = o(N)\), as is the case in the examples below, the main term of the asymptotic expression will be \(\sqrt{2N^2}\).

Spherical codes obtained from SRGs have an additional property of forming tight frames for \(\mathbb{R}^{n_{1,2}}\) or \(\mathbb{R}^{n_{2,2}}\). Recall that a spherical code \(C_N = \{z_1, \ldots, z_N\}\) forms a **tight frame** for \(\mathbb{R}^d\) if \(\sum_{i=1}^N (x \cdot z_i)^2 = ||x||^2\) for any
\( x \in \mathbb{R}^n \), where \( A \) is a constant. A necessary and sufficient condition for the tight frame property to hold is the equality [7]

\[
\sum_{i,j=1}^{N} (z_i \cdot z_j)^2 = \frac{N^2}{n}.
\] (26)

In the frame theory literature the sum on the left-hand side of (26) is called the frame potential [50].

It turns out that all two-distance tight frames are obtained as spherical embeddings of SRGs [5, 49].

**Examples.**

The families of graphs considered below are taken from the online database [20].

1. Graph of points on a quadric in \( \text{PG}(2m, q) \). The parameters of the SRG are

\[
v = \frac{q^{2m} - 1}{q - 1}, \quad k = \frac{q(q^{2m-2} - 1)}{q - 1}, \quad a = \frac{q^2(q^{2m-4} - 1)}{q - 1} + q - 1, \quad c = \frac{q^{2m-2} - 1}{q - 1},
\]

and the eigenvalues are \( r_{1,2} = \pm q^{m-1} - 1 \). Spherical embeddings of this graph give tight frames in dimensions (22)

\[
n_{1,2} = \frac{1}{2}(N - 1 \pm q^m) \approx \frac{1}{2}(N \pm \sqrt{N}),
\]

which is easily seen since \( \sqrt{\Delta} = 2q^{m-1} \). The size of the code \( C_N = C_N(r_1) \) is \( N = v \) and the sum of distances is computed from (25) and equals

\[
\tau_{n_1}(C_N) = N \sqrt{2}(q^m + 1) \left[ \frac{q^{m-1} - 1}{q - 1} \sqrt{q(q^m - 1)} + q^{\frac{3m-2}{2}} \right].
\]

Taking \( m \to \infty \), we compute

\[
\tau_{n_1}(C_N) = \sqrt{2}N^2 - \frac{5}{4\sqrt{2}}N + O(1). \quad (27)
\]

Since in this case \( N \approx 2n_1 - 2\sqrt{2n_1} \), the appropriate bound to look at is \( \tau_2(n, N) \) with \( \delta = 2 \). The second term of the sum of distances in (27) is approximately \(-0.884N \) while the second term in (13) is \(-2(\sqrt{2} - 1)N \approx -0.828N \).

Likewise, the projection on the eigenspace \( W_{r_2} \) gives a spherical code \( C_N = C_N(r_2) \) whose sum of distances equals

\[
\tau_{n_2}(C_N) = N \sqrt{2}(q^m - 1) \left[ \frac{q^{m-1} + 1}{q - 1} \sqrt{q(q^m - 1)} + q^{\frac{3m-2}{2}} \right].
\]

For large \( m \) this behaves as \( \sqrt{2}N^2 - \frac{5}{4\sqrt{2}}N + O(1) \), exhibiting similar behavior as the code in dimension \( n_1 \).

2. Graph of points on a hyperbolic quadric in \( \text{PG}(2m - 1, q) \). The parameters of the SRG are

\[
v = \frac{q^{2m-1} - 1}{q - 1} + q^{m-1}, \quad k = \frac{q(q^{2m-3} - 1)}{q - 1} + q^{m-1}, \quad a = k - q^{2m-3} - 1, \quad c = k/q, \quad (28)
\]

and the eigenvalues are \( r_1 = q^{m-1} - 1 \) and \( r_2 = -q^{m-2} - 1 \). Using (28), we obtain that the dimensions of the spherical embeddings of this graph are

\[
n_1 = \frac{q(q^m - 2 + 1)(q^m - 1)}{q^2 - 1}, \quad n_2 = \frac{q^2(q^{2m-2} - 1)}{q^2 - 1}
\]

and thus, \( n_1 \approx N/(q + 1) \), \( n_2 \approx Nq/(q + 1) \). The sum of distances in \( C_N(r_1) \) is found to be

\[
\tau_{n_1}(C_N) = N \sqrt{2q(q^m + 1)} \left[ \frac{q^{m-1} - 1}{q - 1} \sqrt{q^{m-2} + 1} + q^{\frac{3m-2}{2}} \right].
\]
For large \( m \) we obtain \( \tau_{n_1}(C_N) = \sqrt{2}N^2 - \frac{4+4}{4\sqrt{2}}N - O(1) \). At the same time, from the bound (9) we obtain an upper estimate of the form \( \sqrt{2}N^2 - O(N) \), giving the second term of the same order, although with a smaller constant factor.

Turning to the code \( \mathcal{C}_N \) obtained by projecting on the eigenspace \( W_r \), we find that

\[
\tau_{n_2}(\mathcal{C}_N) = N\sqrt{2(2^{q^m-1}) \left\lfloor \frac{q^{m-2} + 1}{q - 1} \sqrt{q(q^{m-1} - 1)} + q^{2m-2} \right\rfloor},
\]

yielding \( \tau_{n_2}(\mathcal{C}_N) = \sqrt{2}N^2 - \frac{4q-1}{4q\sqrt{2}}N - O(1) \), with similar conclusions in regards to asymptotics of the upper bound.

Remark: It is known [7] that \( N^2/n \) is the smallest value of the frame potential in over all \( (n, N) \) spherical codes. Thus, two-distance tight frames form spherical codes in \( R^n \) that have asymptotically maximum sum of distances while also minimizing the frame potential.

3.3. Spherical embeddings of binary codes. Infinite sequences of asymptotically optimal spherical codes can be obtained by spherical embeddings of binary codes. Let \( \mathcal{C}_N \subset X_n = \{0,1\}^n \) be a binary code of length \( n \) and cardinality \( N \), and denote by \( A_w = \frac{1}{N}\#\{a, b \in C : d_H(a, b) = w\} \) the average number of neighbors of a code vector at Hamming distance \( w \). The \( (n+1) \)-tuple \( (A_0, A_1, \ldots, A_n) \) is called the distance distribution of the code \( \mathcal{C}_N \). For a vector \( z \in X_n \) denote by \( \bar{z} \) the \( n \)-dimensional real vector given by \( \bar{z}_i = (-1)^n / \sqrt{n}, i = 1, \ldots, n \), and let \( \mathcal{E}_N \subset S^{n-1} \) be the spherical embedding of the code \( \mathcal{C}_N \). Since \( \|x - y\| = 2\sqrt{d_H(x, y)}/n \), the sum of distances in \( \mathcal{E}_N \) can be written as

\[
\sum_{i,j=1}^N \|\bar{z}_i - \bar{z}_j\| = \frac{2N}{\sqrt{n}} \sum_{w=0}^n A_w\sqrt{w}.
\]

Using this correspondence, we give several examples of asymptotically optimal families of spherical codes.

3.3.1. Sidelnikov codes. In [45, Thm. 7], Sidelnikov constructed a class of binary linear codes \( C_r, r \geq 1 \) with the parameters \( n = \frac{2^{r-1} - 1}{2^r + 1}, N = 2^r \). The distance distribution of the codes has two nonzero components (in addition to \( A_0 = 1 \)):

\[
w_1 = \frac{2^{4r-1} - 2^{2r-1}}{2^r + 1}, \quad A_{w_1} = 2^r - n - 1,
\]

\[
w_2 = \frac{2^{4r-1} + 2^{3r-1}}{2^r + 1}, \quad A_{w_2} = n.
\]

Let us compute the sum of distances of the spherically embedded Sidelnikov codes. Using (29), we obtain

\[
\frac{2N}{\sqrt{n}}(A_{w_1}\sqrt{w_1} + A_{w_2}\sqrt{w_2})) = \sqrt{2}\left(\frac{N^2}{2} - \frac{1}{8}N^{5/4} - \frac{7}{16}N - \frac{13}{128}N^{3/4}\right) + O(N^{1/2}).
\]

At the same time, the bounds (14) and (9) imply that for any sequence of codes \( \mathcal{C}_N \) with \( N \) as above and \( s = 1 - 2w_1/n \)

\[
\sqrt{2}N^2 - \frac{1}{2\sqrt{2}}N^{7/4} - O(N^{11/8}) \leq \tau_n(\mathcal{C}_N) \leq \sqrt{2}\left(\frac{N^2}{2} - \frac{1}{8}N^{5/4} - \frac{7}{16}N - \frac{5}{128}N^{3/4}\right) + O(N^{1/2}),
\]

and so as \( r \to \infty \) the true value agrees with the upper bound in the first three terms. The first few values of the sum of distances together with the bounds of Sec. 2 are shown in the table below.
The relative difference between the upper bound and the true value for \( r = 5 \) is about \( 10^{-9} \), and the upper and lower bounds on the sum of distances are also rather close.

We next discuss some families of spherical codes obtained from binary codes of cardinality \( N \approx n^2 \) that share the following common property: they have a small number of nonzero distances concentrated around \( n/2 \). Since the factor \( \sqrt{n} \approx \sqrt{\frac{n}{2}} \) for large \( n \) can be taken outside the sum in (29), and since the nonzero coefficients \( A_w \) add to \( N - 1 \), all such families satisfy
\[
\tau_n(C_N) \sim \sqrt{2N^2}(1 + o(1)),
\]
differing only in the lower terms of the asymptotics.

3.3.2. Kerdock codes. [43, §15.5]. Binary Kerdock codes form a family of nonlinear codes of length \( n = 2^m \), \( m \geq 2 \) and cardinality \( N = n^2 \). The distribution of Hamming distances does not depend on the code point and the nonzero entries \( (A_i) \) are as follows:
\[
A_0 = A_n = 1, A_{(n \pm \sqrt{n})/2} = n(n/2 - 1), A_{n/2} = 2(n - 1).
\]
From (29), the sum of distances of the spherical Kerdock code equals
\[
\tau_n(\tilde{C}_N) = \sqrt{2N^2} - \frac{1}{4\sqrt{2}}N^{3/2} + O(N),
\]
which agrees with the bound (4), (14). Note that for general completely monotone potentials, the first-term optimality of the Kerdock codes was previously observed in [13].

3.3.3. Dual BCH codes. [43, §15.4]. Let \( C_N \) be a binary linear BCH code of length \( n = 2^r - 1 \), \( r \geq 3 \) with minimum distance \( 5 \). Suppose that \( r \) is odd. Then the dual code \( (C_N)^\perp \) has cardinality \( N = 2^{2r} \) and distance distribution \( A_0 = 1 \) and
\[
A_{n+1 \pm \sqrt{n+1}} = n\left(\frac{n+1}{4} \mp \sqrt{\frac{n+1}{2}}\right), A_{n+1} = \frac{n(n+3)}{2}.
\]
For \( r \) even the dual BCH code of length \( 2^r - 1 \) has distance distribution \( A_0 = 1 \) and
\[
A_{n+1 \pm \sqrt{n+1}} = \frac{1}{2}n\sqrt{n+1}\left(\sqrt{\frac{n+1}{4}} \pm 1\right), A_{n+1} = \frac{1}{3}n\sqrt{n+1}\left(\sqrt{n+1} \pm 1\right)
\]
\[
A_{n+1} = n\left(\frac{n+1}{4} \pm 1\right).
\]
Using (29), we find that the sum of distances in both cases comes out to be
\[
\tau_n((\tilde{C}_N)^\perp) = \sqrt{2N^2} - \frac{1}{4\sqrt{2}}N^{3/2} - O(N).
\]
Note that \( \tau_n((\tilde{C}_N)^\perp) \) follows closely the upper bound (4).

Many more similar examples can be given using the known results on binary codes with few weights [43, Ch.15], [22, 27, 42, 51] (this list is far from being complete). At the same time, obviously there are sequences of binary codes \( (C_N) \) that yield spherical codes whose sum of distances differs significantly from \( \sqrt{2N^2} \). For instance, consider the code \( C_N \) formed of \( \binom{n}{2} \) vectors of Hamming weight 2, then the pairwise distances are 2 and 4, and a calculation shows that \( \tau_n(\tilde{C}_N) = (2N)^{7/4}(1 + o(1)) \).
4. Sum of distances and bounds for quadratic discrepancy of binary codes

An analog of Stolarsky’s identity (3) for the Hamming space $X_n = \{0, 1\}^n$ was recently derived in [4]. For a binary code $\mathcal{C}_N \subset X_n$ define the quadratic discrepancy as follows:

$$D_b^{L^2}(\mathcal{C}_N) = \sum_{t=0}^n \sum_{x \in X} \left( \frac{|B(x, t) \cap \mathcal{C}_N|}{N} - \frac{v(t)}{2^n} \right)^2,$$

where $B(x, t) = \{ y \in X_n : d_H(x, y) \leq t \}$ is the Hamming ball centered at $x$ and $v(t) = \sum_{i=0}^t \binom{n}{i}$ is its volume. Note that we again abuse the terminology since strictly speaking, $D_b^{L^2}(\mathcal{C}_N)$ is a square of the discrepancy; see also footnote 1 above. We use the subscript $b$ to differentiate this quantity from its spherical counterpart defined in (2). To state the Hamming space version of Stolarsky’s identity, let us define a function $\lambda : \mathbb{Z} \to \mathbb{Z}$. By definition, $\lambda(0) = 0$ and for $w = 2i, 1 \leq i \leq \lfloor n/2 \rfloor$

$$\lambda(w - 1) = \lambda(w) = 2^{n-w} i \binom{w}{i}. \quad (30)$$

An analog of relation (2) in the binary case has the following form:

$$D_b^{L^2}(\mathcal{C}_N) = \frac{n}{2^n+1} \binom{2n}{n} - \frac{1}{N^2} \sum_{i,j=1}^N \lambda(d_H(z_i, z_j)).$$

The average value of $\lambda(\cdot)$ over the code can be written in the form

$$\frac{1}{N^2} \sum_{i,j=1}^N \lambda(d_H(z_i, z_j)) = \frac{1}{N} \sum_{w=1}^n A_w \lambda(w), \quad (31)$$

where $(A_w, w = 1, \ldots, n)$ is the distribution of distances in $\mathcal{C}_N$ defined above. Thus, the value of discrepancy of the code is determined once we know the average “energy” for the potential $\lambda$, denoted $\langle \lambda \rangle_{\mathcal{C}_N}$. Some estimates of this quantity were proved in [4].

In this section we note that the bounds on the sum of distances derived above in Sec. 2 imply bounds on $\langle \lambda \rangle_{\mathcal{C}_N}$ via the spherical embedding, and thus also imply bounds on $D_b^{L^2}$. Our results are based on the following simple observation.

**Proposition 4.1.** Let $n$ be even and let $\mathcal{C}_N \subset X_n$ be a binary code and let $\mathcal{C}_N \subset S^{n-1}$ be its spherical embedding. We have

$$\langle \lambda \rangle_{\mathcal{C}_N} \leq \frac{2^{n-1}}{N^2} \sqrt{\frac{n}{\pi}} r_n(\mathcal{C}_N) \quad (32)$$

**Proof.** Assume that $n$ is even. From (31) and (30) we obtain

$$\frac{1}{N} \sum_{i,j=1}^N \lambda(d_H(z_i, z_j)) = \sum_{w=1}^{n/2} A_w \lambda(w) \leq \sum_{i=1}^{n/2} (A_{2i-1} + A_{2i}) 2^n \sqrt{i/\pi} \leq \frac{2^{n-1/2}}{\sqrt{\pi}} \sum_{i=1}^{n/2} (A_{2i-1} + A_{2i}) \sqrt{2i} \leq \frac{2^n}{\sqrt{\pi}} \sum_{w=1}^n A_w \sqrt{w}$$

where for the first inequality we used the estimate $i \binom{2i}{i} \leq \sqrt{i/\pi} 2^i$, valid for all $i$. Substituting the value of the sum from (29), we obtain the claim. \( \square \)

With minor differences, this result is also valid for odd $n$.

Earlier results [4, Thm.5.2] give several estimates for average value of $\lambda$; for instance, for $n = 2l - 1, l$ even

$$\langle \lambda \rangle_{\mathcal{C}_N} \leq \lambda(l)(1 - \frac{1}{2N}).$$
Using this inequality and estimating the binomial coefficient, we obtain
\[ \langle \lambda \rangle_{C_n} \leq 2^{n-1} \frac{L}{2} \left( \frac{1}{1/2} \right) \leq 2^{n-1/2} \sqrt{\frac{1}{\pi}}, \] (33)
valid for all odd \( n \). While in [4] inequality (30) is proved by linear programming in the Hamming space, similar estimates are also obtained from (32) and the upper bounds (7)-(9) (for \( N \) in the range of their applicability), and they largely coincide with earlier results. For instance, using (32) and a bound of the form (14) with \( N = \delta n^2 \), we obtain \( \langle \lambda \rangle_{C_n} \leq 2^{n-1/2} \sqrt{\frac{1}{\pi}} (1 - O(N^{-1/2})) \), which is only slightly inferior to (33).

In summary, spherical embeddings of binary codes give an alternative way of proving lower bounds for their quadratic discrepancy.

5. PROOFS OF THE BOUNDS

In this section, we prove the bounds on the sum of distances stated in Sec. 2, using the energy function \( E_h(n, N) \) with \( h(t) = L(t) = -\sqrt{2(1-t)} \) (the negative distance). Accordingly, the upper and lower bounds of Sec. 2 exchange their roles. All the derivatives \( L^{(i)}(t) \), \( i \geq 1 \), are defined and positive in \([-1, 1] \) and \( \lim_{t \to 1^-} L^{(i)}(t) = +\varepsilon \). \( L(t) + 2 \) is nonnegative and increasing in \([-1, 1] \), and thus \( L(t) \) is absolutely monotone up to an additive constant. Thus, \( L(t) \) fits the frameworks for ULB and UUB from [14] and [16], respectively (the possible ULB application was mentioned already in the introduction of [14]).

5.1. Derivation of the necessary parameters. Here we explain the choice of the parameters in the Levenshtein framework used to derive the bounds.

The parameters \( k, \varepsilon, m = 2k - 1 + \varepsilon \), and \( (\rho_i, \alpha_i) \), \( i = 0, 1, \ldots, k - 1 + \varepsilon \), originate in the paper of Levenshtein [40] (see also [41, Section 5]), where the author used them to establish optimality of his bound on the size of codes (see Theorem 5.38 in [41]).

For each positive integer \( m = 2k - 1 + \varepsilon \), where \( \varepsilon \in \{0, 1\} \) accounts for the parity of \( m \), Levenshtein used the degree \( m \) polynomial
\[ f_m^{(n,s)}(t) = (t - \alpha_0)^{2-\varepsilon} (t - \alpha_{k-1+\varepsilon}) \prod_{i=1}^{k-2+\varepsilon} (t - \alpha_i)^2 \]
to obtain his universal upper bound \( L_m(n, s) \) on the maximal cardinality of a code on \( S^{n-1} \) with separation \( s \). The numbers \( \alpha_0 < \alpha_1 < \cdots < \alpha_{k-1+\varepsilon} \) belong to \([-1, 1] \) and \( \alpha_{k-1+\varepsilon} = s \) and \( \alpha_0 = -1 \) if and only if \( \varepsilon = 1 \). The polynomial \( f_m \) can be written in the form
\[ f_m^{(n,s)}(t) = (t + 1)^{\varepsilon} \left( P_h(t)P_{k-1}(s) - P_k(s)P_{k-1}(t) \right)^2 / (t - s), \] (34)
where \( P_i(t) = P_i^{(n-1, \varepsilon)}(t) \) is the Jacobi polynomial normalized to satisfy \( P_i(1) = 1 \). For small \( m \) the zeros \( \alpha_i \) of \( f_m \) can be easily found.

The quadrature formula
\[ f_0 = \frac{f(1)}{L_m(n, s)} + \sum_{i=0}^{k-1+\varepsilon} \rho_i f(\alpha_i), \] (35)
which is exact for all real polynomials \( f(t) = \sum_{i=0}^{d} f_i P_i^{(n)}(t) \) of degree \( d \leq m \), reveals a strong relation between the Levenshtein bounds and the energy bounds, as explained in the next paragraph (for more details, see [14, Section 2.2] and [16, Section 3.1]). We also use (35) to calculate the weights \( \rho_i \); see, for example, [12], where the formulas for \( P_i \) for odd \( m \) were derived from a Vandermonde-type system. We also note that \( L_m(n, s) = f_m^{(n,s)}(1)/f_0 \), where \( f_0 \) is the constant coefficient of \( f_m^{(n,s)} \).

Formula (35) is instrumental in the representation (5) of the ULB for the energy \( E_h(C_N) \) and the proof of its optimality in [14]. For ULB, we need polynomials that are positive definite (i.e., their Gegenbauer expansions have nonnegative coefficients) and such that \( f \leq h \) in \([-1, 1] \). First, \( m = 2k - 1 + \varepsilon \) is
determined by the rule \( N \in [D^*(n, m), D^*(n, m + 1)] \). Hermite interpolation with \( f(\alpha_i) = h(\alpha_i) \), where the nodes \( \alpha_i, i = 0, 1, \ldots, k - 1 + \varepsilon \) arise as the roots of \( L_m(n, s) = N \) considered as an equation in \( s \), provides an LP polynomial satisfying both requirements [14, Theorem 3.1]. Then the quantity \( f(0)N - f(1) \), which gives rise to the ULB, is computed from (35) (applied with \( L_m(n, s) = N \)) to give the right-hand side of (5). Note that eventually everything is determined by \( n \) and \( N \). We will see how it works in practice in Section 5.2.

We next explain the derivation of the universal upper bound (UUB) from [16] (see Section 3.2 in that paper) which is based on choice of polynomials

\[
 f(t) = -\lambda f_m^{(n,s)}(t) + g_T(t)
\]

for given \( n, N, \) and \( s \). As mentioned in the Introduction, the polynomial \( f(t) \) has to satisfy \( f \geq h \) for \( t \in [-1, s] \) and to have \( f_i \leq 0 \) for \( i \geq 1 \) in its Gegenbauer expansion. To fulfil these conditions, \( f_m^{(n,s)}(t) \) is taken to be the degree-\( m \) Levenshtein polynomial (34), \( g_T(t) \) interpolates the potential function at the multiset \( T \), which consists of the roots of \( f_m^{(n,s)}(t) \) (counted with their multiplicities; this means that the degree of \( g_T \) is \( m - 1 \)) and \( \lambda = \max\{g_i/\ell_i : 1 \leq i \leq m - 1\} \) is a positive constant. More specifically, where

\[
 f_m^{(n,s)}(t) = \sum_{i=0}^{m} \ell_i P_i^{(n)}(t), \quad g_T(t) = \sum_{i=0}^{m-1} g_i P_i^{(n)}(t)
\]

are the Gegenbauer expansions of \( f_m^{(n,s)}(t) \) and \( g_T(t) \), respectively (note that \( \ell_i > 0 \) for every \( i \leq m \) [41, Theorem 5.42]). The parameter \( N_1 \) \( = L_m(n, s) \geq N \), computed for given \( n \) and \( s \) (the latter determining \( m \) uniquely), is used to find the parameters \( \rho_i \) and \( \alpha_i \) exactly as in the ULB part (but with \( N_1 \) instead of \( N \); for this to work we assume that \( N_1 = L_m(n, s) \in [D^*(n, m), D^*(n, m + 1)] \)). Note that the equality \( N_1 = N \) holds if and only if there exists a universally optimal code of size \( N \) in \( n \) dimensions (in this case, ULB and UUB coincide). In our computations of UUBs below we first find the Hermite interpolant \( g_T(t) \), then the parameter \( \lambda \) (which already gives \( f(t) \)), and finally compute the bound (6).

5.2. Lower bounds.

**Proposition 5.1.** For \( 2 \leq N \leq n + 1 \) we have

\[
 E_L(n, N) \geq -\tau_1(n, N).
\]

(36)

For \( n + 1 \leq N \leq 2n \), we have

\[
 E_L(n, N) \geq -\tau_2(n, N).
\]

(37)

For \( 2n \leq N \leq n(n + 3)/2 \), we have

\[
 E_L(n, N) \geq -\tau_3(n, N).
\]

(38)

where \( \tau_1, \tau_2, \) and \( \tau_3 \) are defined in (7)-(9).

These estimates constitute the first three bounds in (5), beginning with expressing the parameters \( (\rho_i, \alpha_i) \) as functions of the dimension \( n \) and cardinality \( N \in [D^*(n, m), D^*(n, m + 1)] \), \( m = 1, 2, 3 \). In all three proofs below we first find the roots \( \alpha_i \) of the Levenshtein polynomial (34) setting \( L_m(n, s) = N \) for \( m = 1, 2, 3 \), respectively. This is equivalent to solving in \( s \) the equation \( L_m(n, s) = N \). Then we give the weights \( \rho_i \), computed by setting suitable polynomials (we used \( f(t) = 1, t, t^2, t^3 \); for example \( f(t) = 1 \) gives the identity \( \sum_{k=1}^{m} \rho_i = 1 - 1/N \) in the quadrature formula (35).

**Proof of (36).** For the degree 1 bound (36) we have \( \alpha_0 = -1/(N - 1) \) and \( \rho_0 = -1/N\alpha_0 = (N - 1)/N \). Therefore

\[
 E_L(n, N) \geq N^2 \rho_0 L(\alpha_0) = N(N - 1)L(\alpha_0) = -N \sqrt{2N(N - 1)}.
\]

\[\square\]

\[\text{Having said that, we may view the difference between the ULB and UUB as a measure of how far the codes are from being universally optimal.}\]
Proof of (37). For degree 2 (with $k = 1$ and $\varepsilon = 1$) we have $\alpha_0 = -1$, $\alpha_1 = -\frac{2n-N}{n(N-2)}, \rho_0 = \frac{N-n-1}{N+n+4n}$ and $\rho_1 = \frac{n(N-2)^2}{N(N+n+4n)}$. Since $L(-1) = -2$ and $L(\alpha_1) = -\sqrt{\frac{2N(n-1)}{n(N-2)}}$, we obtain that the expression $N^2(\rho_0 L(\alpha_0) + \rho_1 L(\alpha_1))$ from (5) is equal to $-\tau_2(n, N)$ as given in (8).

Proof of (38). For the degree-3 lower bound we take $k = 2$ and $\varepsilon = 0$. By (5) we have

$$E_L(n, N) \geq N^2(\rho_0 L(\alpha_0) + \rho_1 L(\alpha_1)),$$

(39)

where $N \in [D^*(n, 3), D^*(n, 4)] = [2n, n(n + 3)/2]$, and

$$\alpha_{0,1} = \frac{-n(n-1) \pm \sqrt{D}}{2n(N-n-1)}, \quad D = n^2(n-1)^2 + 4n(N-n-1)(N-2n),$$

are the roots of the quadratic equation $n(N-n-1)s^2 + n(n-1)s + 2n-N = 0$ obtained from the equality $L_3(n, s) = N$. Further, the weights $\rho_0$ and $\rho_1$ satisfy the formulas

$$\rho_0 N = \frac{1-\alpha_1^2}{\alpha_0(\alpha_1^2 - \alpha_0^2)}, \quad \rho_1 N = \frac{1-\alpha_0^2}{\alpha_1(\alpha_0^2 - \alpha_1^2)}$$

(note that the numerators resemble the potential $L(t)$ computed for $\alpha_0, \alpha_1$; this will make our expressions symmetric). In the sequel, we use the following symmetric expressions for $\alpha_0$ and $\alpha_1$

$$\alpha_0 + \alpha_1 = -\frac{n-1}{N-n-1}, \quad \alpha_0 \alpha_1 = -\frac{N-2n}{n(N-n-1)}, \quad \alpha_0^2 - \alpha_1^2 = \frac{(n-1)^2\sqrt{D}}{n(N-n-1)^2},$$

$$(1-\alpha_0)(1-\alpha_1) = \frac{(n-1)N}{n(N-n-1)}, \quad (1+\alpha_0)(1+\alpha_1) = \frac{(n-1)(N-2n)}{n(N-n-1)}.$$

Our task is to express the bound (39) via $n$ and $N$. Using the above equalities, we obtain

$$E_L(n, N) \geq N(\rho_0 NL(\alpha_0) + \rho_1 NL(\alpha_1))$$

$$= -N\left(\frac{(1-\alpha_1^2)\sqrt{2(1-\alpha_0)}}{\alpha_0(\alpha_1^2 - \alpha_0^2)} + \frac{(1-\alpha_0^2)\sqrt{2(1-\alpha_1)}}{\alpha_1(\alpha_0^2 - \alpha_1^2)}\right)$$

$$= -\frac{n^2N(N-n-1)^3}{(n-1)(N-2n)\sqrt{D}} \left(\alpha_1(1-\alpha_1^2)\sqrt{2(1-\alpha_0)} - \alpha_0(1-\alpha_0^2)\sqrt{2(1-\alpha_1)}\right).$$

Consider the expression $S = \alpha_1(1-\alpha_1^2)\sqrt{2(1-\alpha_0)} - \alpha_0(1-\alpha_0^2)\sqrt{2(1-\alpha_1)}$. We compute

$$\frac{S^2}{2} = \frac{(n-1)(A-B)N}{n(N-n-1)},$$

and thus

$$S = \sqrt{\frac{2(A-B)(n-1)N}{n(N-n-1)}},$$

where we have denoted

$$A = \frac{(n-1)(N-2n)^2[Nn^3 + (2N-1)n^2 - (N-1)(7N-2)n + (N-1)^2(2N+3)]}{n^2(N-n-1)^5}$$

and

$$B = \frac{-2(n-1)(N-2n)^2\sqrt{(n-1)N}}{(n(N-n-1))^{5/2}}.$$ 

Therefore

$$E_L(n, N) \geq -\frac{nN(N-n-1)^2}{(N-2n)\sqrt{D}} \sqrt{\frac{2(A-B)nN(N-n-1)}{n-1}}.$$
Performing simplifications under the square root, we obtain

\[
\frac{2(A - B)nN(N - n - 1)}{n - 1} = 2nN(N - n - 1) \left( \frac{(N - 2n)^2 A_1}{n^2(N - n - 1)^5} + \frac{2(N - 2n)^2 \sqrt{N(N - n - 1)}}{n^{5/2}(N - n - 1)^{5/2}} \right)
\]

\[
= \frac{2N(N - 2n)^2}{n^4(N - n - 1)^4} \left( n^3 A_1 + 2 \sqrt{N(n - 1)n^6(N - n - 1)^6} \right)
\]

\[
= \frac{2N(N - 2n)^2}{n^2(N - n - 1)^4} \left( nA_1 + 2(N - n - 1)^2 B_1 \right)
\]

with \( A_1 \) and \( B_1 \) as in (10) and (11), respectively. Upon substituting this back into the bound for \( E_L(n, N) \), we obtain

\[
E_L(n, N) \geq -\frac{\sqrt{2}N(nA_1 + 2(N - n - 1)^2 B_1)}{\sqrt{D}},
\]

establishing the bound (38) with \( \tau_3(n, N) \) as in (9).

5.3. Upper bounds. In this section we prove bounds (16)-(18), deriving an explicit form of the first three universal upper bounds for \( \mathcal{C}_N(n, s) \) codes from [16] for \( L(t) \) as functions of \( n, N \) and \( s \). In addition to the parameters \( (\rho_1, \alpha_1) \) as explained above (but now related to \( N_1 = L_m(n, s) \) instead of \( N \)), we need to find the polynomial \( g_T(t) \), then the real parameter \( \lambda \) and finally the polynomial \( f(t) \) as explained in the last paragraph of Section 5.1. Recall again that because of the sign change, the inequalities (16)-(18) are inverted.

**Proposition 5.2.** For \( N \in [2, n + 1] \) and \( s \in [-1/(N - 1), -1/n] \), we have

\[
E_L(n, N, s) \leq -\tau^{(1)}(n, N, s).
\] (40)

For \( N \in [n + 1, 2n] \) and \( s \in [(N - 2n)/n(N - 2), 0] \), we have

\[
E_L(n, N, s) \leq -\tau^{(2)}(n, N, s).
\] (41)

For \( N \in [2n, n(n + 3)/2] \) and \( s \in \left[ \frac{N^2(n-1)^2 + 4n(N-n-1)(N-2n)-n(n-1)}{2n(N-n-1)}, \frac{N^2+3-1}{n+2} \right] \), we have

\[
E_L(n, N, s) \leq -\tau^{(3)}(n, N, s)
\] (42)

where the quantities \( \tau^{(1)}, \tau^{(2)}, \tau^{(3)} \) are defined in (16)-(18) above.

**Remark 5.1.** We set upper limits for \( s \) in all three cases as suggested implicitly by the framework in [16]. The bounds are valid beyond these limits but most likely they can be improved by polynomials of higher degrees.

**Proof of (40).** For fixed \( n, N \in [2, n + 1] \) and \( s \in [-1/(N - 1), -1/n] \), we consider the degree 1 UUB

\[
E_L(n, N, s) \leq N \left( \frac{N}{L_1(n, s)} - 1 \right) f(1) + N^2 \rho_0 L(s),
\]

where the parameters are as follows: \( L_1(n, s) = (s - 1)/s =: N_1 \) is the first Levenshtein bound,

\[
f(t) = -\lambda f_1^{(n, s)}(t) + g_T(t) = -\lambda(t - s) + g_T(t)
\]

is our linear programming polynomial, and \( \alpha_0 = s, \rho_0 = -1/N_1 s = 1/(1 - s) \) are Levenshtein’s parameters corresponding to \( s \) (i.e., to \( N_1 \)). The polynomial \( g_T(t) \) is constant and is found from \( g_T(s) = L(s) \). Then \( \lambda = 0 \) and \( f(t) = L(s) \) give the bound

\[
E_L(n, N, s) \leq \left( \frac{N}{N_1} - 1 \right) N L(s) + N^2 \rho_0 L(s) = N(N - 1) L(s).
\]

**Remark 5.2.** As already observed, this bound is straightforward upon estimating all terms in the energy sum \( E_L(\mathcal{C}_N) \) by the constant \( L(s) \).
Proof of (41). For fixed \( n, N \in [n + 1, 2n] \) and \( s \in [(N - 2n)/n(N - 2), 0] \), we consider the degree 2 UUB following the derivation in [16]

\[
E_L(n, N, s) \leq N \left( \frac{N}{L_2(n, s)} - 1 \right) f(1) + N^2(\rho_0 L(\alpha_0) + \rho_1 L(\alpha_1)),
\]

(43)

where the parameters are defined as follows: \( N_1 := L_2(n, s) = 2n(1-s)/(1-ns) \) is the second Levenshtein bound,

\[
f(t) = -\lambda f_2^{(n,s)}(t) + g_T(t) = -\lambda(t + 1)(t - s) + g_T(t)
\]
is our linear programming polynomial (to be described below), and

\[
\alpha_0 = -1, \quad \alpha_1 = s, \quad \rho_0 = \frac{N_1 - n - 1}{N_1 n + N_1 - 4n}, \quad \rho_1 = \frac{n(N_1 - 2)^2}{N_1(n_1 + N_1 - 4n)}
\]

are the Levenshtein parameters corresponding to \( s \) (compare with the parameters in the proof of (37)).

The polynomial \( g_T(t) \) with \( T = \{-1, s\} \), i.e. \( g_T(-1) = L(-1), g_T(s) = L(s) \), becomes

\[
gr(t) = \frac{L(s) - L(-1)}{1 + s} t + \frac{L(s) + sL(-1)}{1 + s} = \frac{(2 - \sqrt{2}(1-s))t - 2s - \sqrt{2}(1-s)}{1 + s}
\]

Therefore, \( (43) \) gives

\[
E_L(n, N, s) \leq N \left( \frac{N}{N_1} - 1 \right) (-2) + N^2 \left( \frac{(N_1 - n - 1)(-2)}{N_1 n + N_1 - 4n} + \frac{n(N_1 - 2)^2(-\sqrt{2}(1-s))}{N_1(n_1 + N_1 - 4n)} \right),
\]

implying (41).

\[ \square \]

Proof of (42). For fixed \( n, N \), and \( s \) as in the condition (19), we derive the degree 3 UUB

\[
E_L(n, N, s) \leq N \left( \frac{N}{L_3(n, s)} - 1 \right) f(1) + N^2(\rho_0 L(\alpha_0) + \rho_1 L(\alpha_1)),
\]

(44)

where the parameters are defined as follows:

\[
N_1 := L_3(n, s) = \frac{n(1-s)(n+1)s+2}{1-ns^2}
\]

is the third Levenshtein bound,

\[
f(t) = -\lambda f_3^{(n,s)}(t) + g_T(t) = -\lambda(t - \alpha_0)^2(t - s) + g_T(t)
\]
is the linear programming polynomial to be found, and

\[
\alpha_0 = \frac{-n(n-1) - \sqrt{D_1}}{2n(N_1 - n - 1)} = \frac{1 + s}{1 + ns}, \quad \alpha_1 = \frac{-n(n-1) + \sqrt{D_1}}{2n(N_1 - n - 1)} = s,
\]

\[
D_1 = n^2(n-1)^2 + 4n(N_1 - n - 1)(N_1 - 2n) = \frac{n^2(n-1)^2(1+2s+ns^2)^2}{(1-ns^2)^2},
\]

\[
\rho_0 = \frac{1 - \alpha_0^2}{N_1 \alpha_0 (\alpha_1^2 - \alpha_0^2)} = \frac{(1 + ns)^3}{n((n+1)s+2)(1+2s+ns^2)},
\]

\[
\rho_1 = \frac{1 - \alpha_0^2}{N_1 \alpha_1 (\alpha_1^2 - \alpha_0^2)} = \frac{n-1}{n(1-s)(1+2s+ns^2)},
\]
are the Levenshtein’s parameters corresponding to s (note that they are also shown to depend on n and s only).

The ULB part \( \rho_0 L(\alpha_0) + \rho_1 L(\alpha_1) \) in (44) can be found as in the proof of (38) but with \( N_1 \) instead of \( N \). Explicitly, this means that

\[
\rho_0 L(\alpha_0) + \rho_1 L(\alpha_1) = -\frac{1}{N_1} \sqrt{\frac{2N_1(nA_1 + 2(N_1 - n - 1)^2B_1)}{D_1}},
\]

where \( A_1 \) and \( B_1 \) are as in (10) and (11), respectively, but with \( N_1 \) instead of \( N \), and \( D_1 \) as above (so \( D_1 \) has the same form as \( D \), but with \( N_1 \) instead of \( N \)). We obtain

\[
E_L(n, N, s) \leq \frac{N}{N_1} \left( (N - N_1)f(1) - \frac{N \sqrt{2N_1(nA_1 + 2(N_1 - n - 1)^2B_1)}}{n(n-1)(1+2s+ns^2)} \right),
\]

In order to rewrite (45) in terms of \( n \) and \( s \), we first write the ULB part in terms of \( n \) and \( s \) by using the above expressions, i.e.

\[
A_1 = \frac{(n - 1)^2[(1 + ns)^5(1 - s) + (n - 1)^2((n + 1)s + 2)]}{(1 - ns^2)^3},
\]

\[
B_1 = \frac{n(n-1)\sqrt{(1-s)(1+ns)((n+1)s+2)}}{1-ns^2},
\]

\[
N_1 - n - 1 = \frac{(n-1)(1+ns)}{1-ns^2},
\]

and \( D_1 = D_1(n, s) \) as found above. We find

\[
E_L(n, N, s) \leq \frac{N}{N_1} \left( (N - N_1)f(1) - \frac{(1 - ns^2)N \sqrt{2N_1(nA_1 + 2(N_1 - n - 1)^2B_1)}}{n(n-1)(1+2s+ns^2)} \right)
\]

\[
= \frac{N}{N_1} \left( (N - N_1)f(1) - \frac{N \sqrt{2N_1(nA_2 + 2(1+ns)^2B_2)}}{n(1+2s+ns^2)} \right)
\]

\[
= \frac{N}{N_1} \left( (N - N_1)f(1) - \frac{N \sqrt{2(1-s)((n+1)s+2)(A_2 + 2(1+ns)^2B_2)}}{(1+2s+ns^2)(1-ns^2)} \right),
\]

where \( A_2 \) and \( B_2 \) are as given in (20).

Second, we find \( f(t) \) in order to compute \( f(1) \). The polynomial \( g_T(t) = at^2 + bt + c \) interpolates \( L(t) \) in \( T = \{\alpha_0, \alpha_0, \alpha_1\} \), i.e. \( g(\alpha_0) = L(\alpha_0), g'(\alpha_0) = L'(\alpha_0) \), and \( g(\alpha_1) = L(\alpha_1) \). Resolving this to find \( a, b, \) and \( c \), we obtain the Gegenbauer expansion of \( f(t) \) as follows

\[
f(t) = -\frac{\lambda(n-1)}{n+2} P_3^{(n)}(t) + \frac{(n-1)(a + \lambda(2a_0 + a_1))}{n} P_2^{(n)}(t)
\]

\[
+ \left( b - \frac{\lambda((\alpha_1^2 + 2a_0a_1)(n+2)+3)}{n+2} \right) P_1^{(n)}(t) + \frac{\lambda(a_0^2\alpha_1n + 2a_0 + a_1) + a + cn}{n} P_0^{(n)}(t),
\]

where

\[
a = \frac{L(\alpha_1) - L(\alpha_0) - L'(\alpha_0)(\alpha_1 - \alpha_0)}{(\alpha_1 - \alpha_0)^2},
\]

\[
b = \frac{L'(\alpha_0)(\alpha_1^2 - \alpha_0^2) - 2a_0(L(\alpha_1) - L(\alpha_0))}{(\alpha_1 - \alpha_0)^2},
\]

\[
c = \frac{a_0^2(L(\alpha_1) - L(\alpha_0)) - a_0\alpha_1(\alpha_1 - \alpha_0)L'(\alpha_0) + (\alpha_1 - \alpha_0)^2 L(\alpha_0)}{(\alpha_1 - \alpha_0)^2}.
\]
According to the rule in Theorem 3.2 from [16], the coefficient \( \lambda \) has to be chosen as \( \max\{g_1/\ell_1, g_2/\ell_2\} \), which is equivalent to the choice between \( \{f_1 = 0, f_2 < 0\} \) and \( \{f_1 < 0, f_2 = 0\} \), respectively. We will prove below that \( f_2 < 0 \), i.e., that the first of these conditions is realized for all \( n \) and \( s \) under consideration.

The equality \( f_1 = 0 \) gives

\[
\lambda = \frac{b(n + 2)}{(a_0^2 + 2a_0a_1)(n + 2) + 3} = \frac{(n + 2)(L'(a_0)(a_0^2 - a_0^2) - 2a_0(L(a_1) - L(a_0))}{(a_1 - a_0)^2((a_0^2 + 2a_0a_1)(n + 2) + 3)}.
\]

Then

\[
f(1) = -\lambda(1 - a_0)^2(1 - a_1) + a + b + c = \frac{A_3(L(a_1) - L(a_0)) + B_3L(a_0) - C_3L'(a_0)}{B_3},
\]

where

\[
A_3 = (1 - a_0)^2((n + 2)(1 + a_0)^2 - n + 1) = \frac{(n - 1)((n + 1)s + 2)^2((n - 2)s^2 - 2n - s - 1)}{(1 + ns)^4},
\]

\[
B_3 = (a_1 - a_0)^2((a_0^2 + 2a_0a_1)(n + 2) + 3) = -(1 + 2s + ns^2)((2n + 2)s^3 - (n^2 - 5n - 2)s^2 - 6ns - n - 5)
\]

\[
C_3 = (1 - a_0)(1 - a_1)(a_1 - a_0)((a_0 + a_1 + a_0a_1) + 3) = \frac{(n - 1)(1 - s)((n + 1)s + 2)(1 + 2s + ns^2)((n + 2)s^2 + 2s - 1)}{(1 + ns)^3}.
\]

Therefore

\[
f(1) = \frac{(n + 1)s + 2}{(1 + 2s + ns^2)^2C_4\sqrt{2B_5}}[(1 - s)(1 + ns)A_4 + B_4\sqrt{1 - s}B_5],
\]

where \( A_4, B_4, B_5 \) and \( C_4 \) are as given in (26) in Section 2.

Substituting these parameters into (46) and performing simplifications, we eventually obtain (18):

\[
E_L(n, N, s) \leq \frac{N}{N_1} \left( (N - N_1)f(1) - \frac{N\sqrt{2(1 - s)((n + 1)s + 2)(A_2 + 2(1 + ns)^2B_2)}}{(1 + 2s + ns^2)(1 - ns^2)} \right),
\]

\[
= \frac{N(1 - ns^2)}{n(1 - s)((n + 1)s + 2)} \left( \frac{A_5f(1)}{1 - ns^2} - \frac{N\sqrt{2(1 - s)((n + 1)s + 2)(A_2 + 2(1 + ns)^2B_2)}}{(1 + 2s + ns^2)(1 - ns^2)} \right),
\]

\[
= \frac{NA_5((1 - s)(1 + ns)A_4 + B_4\sqrt{1 - s}B_5)}{n(1 - s)(1 + 2s + ns^2)^2C_4\sqrt{2B_5}} - \frac{N^2\sqrt{2(1 - s)((n + 1)s + 2)(A_2 + 2(1 + ns)^2B_2)}}{n(1 - s)((n + 1)s + 2)(1 + 2s + ns^2)}
\]

\[
= \frac{NA_5((1 - s)(1 + ns)A_4 + B_4\sqrt{1 - s}B_5)}{n(1 - s)(1 + 2s + ns^2)^2C_4\sqrt{2B_5}} - \frac{N^2\sqrt{2(1 - s)(A_2 + 2(1 + ns)^2B_2)}}{n(1 - s)(1 + 2s + ns^2)^2\sqrt{2B_5}},
\]

\[
= \frac{NA_5((1 - s)(1 + ns)A_4 + B_4\sqrt{1 - s}B_5) - 2N(1 + 2s + ns^2)C_4\sqrt{A_6}}{n(1 - s)(1 + 2s + ns^2)^2C_4\sqrt{2B_5}},
\]

where \( A_4, B_1, \) and \( C_4 \) are as given in (26).

The condition \( f_2 < 0 \) is equivalent to \( \lambda(2a_0 + s) + a < 0 \). This gives the inequality

\[
\frac{6B_6\sqrt{(1 - s)(1 + ns)((n + 1)s + 2)} - C_6}{C_4} < 0,
\]
We have $C_4 < 0$ since $2n(n+2)s^3 < n+5$ follows for $n \geq 3$ and $0 < s < (1 - \sqrt{n+3})/(n+2)$ (just use that $s < 1/\sqrt{n+2}$). It remains to see that $6B_6\sqrt{(1-s)(1+ns)((n+1)s+2)} > C_6$. Since $B_6 < 0$ for $0 < s < (1 - \sqrt{n+3})/(n+2)$, we need to prove that $C_6^2 > 36B_6^2(1-s)(1+ns)((n+1)s+2)$. This inequality is reduced to an 8-degree polynomial (in $s$) inequality shown to hold true by a computer algebra system. □

Acknowledgements. We thank the referees for spending time and effort on our manuscript and for providing an extensive set of remarks which improved the exposition.
