Abstract:
Transcatheter aortic valve implantation (TAVI) has been validated as a reliable therapy for aortic stenosis (AS), similar to surgical aortic valve replacement. Due to the methodological differences between the two therapeutic options, each has unique complications. We experienced a hitherto unreported complication of TAVI. An 81-year-old man underwent TAVI for severe AS. Acute mitral regurgitation (MR) occurred during valve deployment. Interference of the guidewire with the mitral subvalvular structure caused transient severe MR, leading to the development of pulmonary hemorrhaging. During TAVI, careful attention should be paid to the position of the guidewire, changes in hemodynamics and degree of MR.

Introduction
Surgical aortic valve replacement and transcatheter aortic valve implantation (TAVI) have been established as reliable therapies for severe aortic stenosis (AS). Because of the great methodological differences between the two procedures, some complications are common to both while other complications are specific to each procedure (1, 2). TAVI-specific complications include coronary obstruction, aortic root rupture, valve embolization, left ventricle rupture and iliac artery injury.

We report a hitherto unreported complication of bilateral pulmonary hemorrhaging caused by acute severe mitral regurgitation (MR) during TAVI.

Case Report
An 81-year-old male was admitted with severe AS due to bicuspid aortic valve together with severe right coronary artery stenosis (aortic valve area: 0.70 cm², peak aortic valve flow: 5.3 m/sec, mean valvular pressure gradient: 60 mmHg). He also had systemic sclerosis, Sjogren syndrome, interstitial pneumonitis necessitating oral corticosteroids and home oxygen therapy, chronic renal failure, carotid artery stenosis, chronic pulmonary obstructive disease and previous pulmonary thromboembolism. The calculated Society of Thoracic Surgeons score for surgical aortic valve replacement was 15.3%. Because of his high surgical risk and moderate frailty, we planned transfemoral TAVI using Core-Valve prosthesis (Medtronic, Minneapolis, MN, USA) under local anesthesia to avoid exacerbation interstitial pneumonitis, under transthoracic echocardiography (TTE) guidance. To perform percutaneous coronary intervention (PCI) concurrently with TAVI, clopidogrel was added to warfarin, which had been taken for the secondary prevention of venous thromboembolism. The international normalized ratio of prothrombin time was controlled to 1.75 before the procedure for possible bleeding.

First, using as little contrast medium possible, interven-
administration of a single antithrombotic with clopidogrel. Gradually decreased in size (Fig. 2C), and we continued the positive pressure ventilation. Pulmonary hemorrhaging continued to expand, we managed to stop the bleeding (Fig. 2A, B and D-F). Although pulmonary hemorrhaging (Fig. 2A, B and D-F). Although pulmonary hemorrhaging continued to expand, we managed to stop the bleeding. The hemoglobin level decreased from 11.6 to 8.1 g/dl on the day after the procedure. Computed tomography demonstrated bilateral pleural hematoma and left lung hemorrhaging (Fig. 2A, B and D-F). Although pulmonary hemorrhaging continued to expand, we managed to stop the bleeding by administering vitamin K, fresh-frozen plasma and hemothropic drug. Respiratory failure was managed by non-invasive positive pressure ventilation. Pulmonary hemorrhaging gradually decreased in size (Fig. 2C), and we continued the administration of a single antithrombotic with clopidogrel. His lung recovered its oxygenation capability, and the patient was discharged home on the 48th postprocedural day.

Discussion

We experienced a case of bilateral pulmonary hemorrhaging caused by acute severe MR during TAVI. During deployment of the CoreValve, interference of the stiff guidewire with the mitral subvalvular structure caused transient severe MR. The elevated intra-cardiac pressure was transmitted from the left ventricle to the left atrium, pulmonary veins, lungs and pleural space, causing bilateral pulmonary hemorrhaging.

Aguilera et al. (3) reported significant MR during TAVI. They documented occurrence or aggravation of significant MR on transesophageal echocardiography in 11 of 129 cases (8.5%). The causes of MR included aortic prosthesis impingement, systolic anterior movement of the anterior mitral leaflet, commissural tearing of the valve and functional mechanism. All significant MR regressed to grade II or less at discharge, and none of the cases required mitral valve surgery. In our case, slight aggravation of MR was observed as the stiff guidewire was inserted, suggesting interference of the guidewire with the subvalvular structure. Stress to the guidewire generated by valve deployment led to transient severe MR. Injury of the mitral valve during TAVI has been reported (4, 5). In our case, MR regressed after valve deployment, suggesting no organic damage to the mitral valve.
Although transesophageal echocardiography is generally superior to transthoracic echocardiography for continuous monitoring and assessment of MR etiology, we used transthoracic echocardiography, as local anesthesia was used for the procedure. Particularly when deploying a transcatheter heart valve, the position of the guidewire, hemodynamic status and degree of MR must be monitored carefully.

Our patient was prone to bleeding because he was taking clopidogrel and warfarin. He had simple and discrete right coronary artery stenosis eligible for PCI, and we chose concurrent PCI performed with TAVI in light of his hemodynamic stability. Because he had been at risk for recurrence of venous thromboembolism during the peri-procedural period, we decided to maintain warfarin at a therapeutic dose, and added clopidogrel to prevent early stent thrombosis after PCI. Warfarin itself carries a possible side effect of pulmonary hemorrhaging, so it may have promoted this unusual complication. Furthermore, his lung and vascular tissues were probably fragile due to chronic corticosteroids therapy. Acute MR transmitted the elevated intra-cardiac pressure retrogradely from the left ventricle to the left atrium, pulmonary veins, lungs and pleural space. This resulted in bilateral pulmonary hemorrhaging. Computed tomography showed calcified pleura suggestive of previous pleuritis, implying the possible existence of abnormal blood vessels that were susceptible to elevated pressure.

We experienced a case of bilateral pulmonary hemorrhaging caused by acute severe MR during TAVI. Careful attention should be paid during TAVI to the position of the guidewire, changes in hemodynamics and degree of MR.
