SUPERCONVERGENCE ANALYSIS OF PARTIALLY PENALIZED IMMERSED FINITE ELEMENT METHOD

HAILONG GUO*, XU YANG†, AND ZHIMIN ZHANG‡

Abstract. The contribution of this paper contains two parts: first, we prove a supercloseness result for the partially penalized immersed finite element (PPIFE) method in [T. Lin, Y. Lin, and X. Zhang, SIAM J. Numer. Anal., 53 (2015), 1121–1144]; then based on the supercloseness result, we show that the gradient recovery method proposed in our previous work [H. Guo and X. Yang, arXiv: 1608.00063] can be applied to the PPIFE method and the recovered gradient converges to the exact gradient with a superconvergent rate $O(h^{3/2})$. Hence, the gradient recovery method provides an asymptotically exact a posteriori error estimator for the PPIFE method. Several numerical examples are presented to verify our theoretical result.

Key words. superconvergence, interface problem, immersed finite element, supercloseness, gradient recovery.

1. Introduction. Recently there has been of great interest in developing finite element method for interface problems where the discontinuous coefficients appear naturally due to the background consisting of rather different materials; see, e.g., [1,4–6,13,14,20,25,27,29,33–36,39,47]. It is well known that classical finite element method work for interface problems provided that the mesh is aligned with the interface [1,3,14,17]. Such requirement may be a heavy burden especially when the interface involves complex geometry and therefore it is difficult and time-consuming to generate a body-fitted mesh. To release the restriction, Li proposed an immersed finite element (IFE) method for the two-point boundary value problem [33]. This idea was further generalized into two-dimensional cases by Li, Lin, and Wu who constructed a nonconforming IFE method for interface problems [36]. The main idea of IFE is to solve interface problems on the Cartesian mesh (or uniform mesh) by modifying basis functions near the interface.

The optimal approximation capability of IFE space was justified in [35]. However, there is no proof for the optimal convergence of the classical IFE method in the two-dimensional setting, see [39], even though plentiful numerical experiments showed optimal convergence for elliptic equations. Interested readers are referred to [17,26,31] for the progress of theoretical results. Moreover, numerical test results demonstrated that classic IFE method [30] achieves only the first order convergence in the $L^\infty$-norm. There is relatively larger point-wise error over interfaces due to the discontinuities of test functions. To eliminate this disadvantage, the authors of [30] added a correction term into the bilinear form of the classic IFE method and [27,29] proposed a new IFE formulation in the framework of the Petrov-Galerkin method. However, the theoretical
foundation of their methods is not fully established. Alternatively, Lin, Lin, and Zhang [39] proposed PPIFE method to penalize the inter-element discontinuity. Thanks to the added penalty term, the authors proved the coercivity of the bilinear form and showed the optimal convergence in the energy norm.

Superconvergence is an active research topic in the finite element community and its theory for smooth problems is well established, see, e.g., [2, 3, 10, 12, 23, 24, 32, 37, 40, 41, 44, 46, 48, 52], and references therein. On the other hand, however, the superconvergence phenomena for interface problems is not yet well understood due to discontinuing of the coefficient crossing the interface. In [45], a supercloseness result between the linear finite element solution and its linear interpolation is proved for a two dimensional interface problem with body-fitted mesh. Recently, the first two authors proposed an immersed polynomial preserving recovery (IPPR) for interface problem and proved the superconvergence on both mildly unstructured mesh and adaptively refined mesh [21]. For IFE method, Chou et al. introduced two special interpolation formula to recover flux more accurately for the one-dimensional linear and quadratic IFE elements [15, 16]. In [9], Cao et al. investigated nodal superconvergence phenomena using generalized orthogonal polynomial in the one-dimensional setting. For the two-dimensional case, the first two authors proposed a new gradient recovery technique [22] for symmetric and consistent IFE method [30] and Petrov-Galerlin IFE method [27–29] and numerically verified its superconvergence. In addition, [22] numerically showed supercloseness results for both symmetric and consistent IFE method and Petrov-Galerlin IFE method.

The main goal of this work is to establish a complete superconvergence theory for the PPIFE method [39]. Our analysis relies on the following three key observations: 1) the solution is piecewise smooth on each sub-domain despite of its low global regularity; 2) the basis functions on non-interface elements are just basis functions for standard linear finite element method; 3) the number of interface elements is roughly $O(h^{-1})$. The above three observations motivate us to divide elements into disjoint types: interior elements, exterior elements, and interface elements. We can obtain the supercloseness using well-known results in [3, 12, 48] on interior and exterior elements, respectively. In addition, the trace inequalities for the IFE functions in [39] and the third observation enable us to establish $O(h^{1.5})$ supercloseness result for interface elements. Our supercloseness result reduces to the standard one as in [3, 12, 48] when the discontinuity disappears. It is consistent with the fact that IFE method becomes the standard linear finite element method when the discontinuity disappears. Furthermore, we show that the gradient recovery method in [22] can also be applied to the PPIFE method. The recovered gradient is proven to be superconvergent to the exact gradient of the interface problem, and therefore, provides an asymptotically exact a posteriori error estimator for PPIFE method.

The rest of the paper is organized as follows. In Section 2, we introduce the model interface problem and the PPIFE method. In Section 3, we first establish the supercloseness between gradients of the PPIFE solution and the exact solution to the interface problem, and then based the supercloseness, we prove the recovered gradient using the method in [22] is superconvergent to the exact gradient. Then provides an asymptotically exact a posteriori error estimator for PPIFE method. In Section 4, we present some numerical experiments to support our theoretical result. Finally, we make some conclusive remarks in Section 5.

2. Preliminary. In this section, we shall introduce the elliptic interface problem, and its discrete form using the PPIFE method [39].
2.1. Elliptic interface problem. Let $\Omega$ be a bounded polygonal domain with Lipschitz boundary $\partial \Omega$ in $\mathbb{R}^2$. A $C^2$-curve $\Gamma$ divides $\Omega$ into two disjoint subdomains $\Omega^-$ and $\Omega^+$, which is typically characterized by zero level set of some level set function $\phi$ \([12, 13]\), with $\Omega^- = \{ z \in \Omega | \phi(z) < 0 \}$ and $\Omega^+ = \{ z \in \Omega | \phi(z) > 0 \}$. We shall consider the following elliptic interface problem

$$
-\nabla \cdot (\beta(z) \nabla u(z)) = f(z), \quad z \in \Omega \setminus \Gamma, \quad (2.1)
$$

$$
u = 0, \quad z \text{ on } \partial \Omega, \quad (2.2)
$$

where the diffusion coefficient $\beta(z) \geq \beta_0$ is a piecewise smooth function, i.e.

$$
\beta(z) = \begin{cases}
\beta^-(z) & \text{if } z \in \Omega^-,
\beta^+(z) & \text{if } z \in \Omega^+, 
\end{cases} \quad (2.3)
$$

which has a finite jump of function values across the interface $\Gamma$. At the interface $\Gamma$, one has the following jump conditions

$$
[u]^r = u^+ - u^- = 0, \quad (2.4)
$$

$$
[\beta u_n]^r = \beta^+ u^+_n - \beta^- u^-_n = g, \quad (2.5)
$$

where $u_n$ denotes the normal flux $\nabla u \cdot n$ with $n$ as the unit outer normal vector of the interface $\Gamma$.

In this paper, we use the standard notations for Sobolev spaces and their associate norms given in \([7, 18, 19]\). For a subdomain $A$ of $\Omega$, let $\mathbb{P}_m(A)$ be the space of polynomials of degree less than or equal to $m$ in $A$ and $n_m$ be the dimension of $\mathbb{P}_m(A)$ which equals to $\frac{1}{2}(m + 1)(m + 2)$. $W^{k,p}(A)$ denotes the Sobolev space with norm $\| \cdot \|_{k,p,A}$ and seminorm $| \cdot |_{k,p,A}$. When $p = 2$, $W^{k,2}(A)$ is simply denoted by $H^k(A)$ and the subscript $p$ is omitted in its associate norm and seminorm. As in \([45]\), denote $W^{k,p}(\Omega^- \cup \Omega^+)$ as the function space consisting of piecewise Sobolev function $w$ such that $w|_{\Omega^-} \in W^{k,p}(\Omega^-)$ and $w|_{\Omega^+} \in W^{k,p}(\Omega^+)$. For the function space $W^{k,p}(\Omega^- \cup \Omega^+)$, define norm as

$$
\|w\|_{k,p,\Omega^- \cup \Omega^+} = (\|w\|_{k,p,\Omega^-}^p + \|w\|_{k,p,\Omega^+}^p)^{1/p},
$$

and seminorm as

$$
|w|_{k,p,\Omega^- \cup \Omega^+} = (|w|_{k,p,\Omega^-}^p + |w|_{k,p,\Omega^+}^p)^{1/p}.
$$

We assume that $T_h$ is a shape regular triangulation of $\Omega$ with $h = \max_{T \in T_h} \text{diam}(T)_h$, and that $h$ is small enough so that the interface $\Gamma$ never crosses any edge of $T_h$ more than once. The elements of $T_h$ can be divided into two categories: regular elements and interface elements. We call an element $T$ interface element if the interface $\Gamma$ passes the interior of $T$; otherwise we call it regular element. If $\Gamma$ only passes two vertices of an element $T$, we treat the element $T$ as a regular element. Let $T^r_h$ and $T^i_h$ denote the set of all interface elements and regular elements, respectively.

Let $N_h$ and $E_h$ denote the set of all vertices and interior edges of $T_h$, respectively. We can divide $E_h$ into two categories: interface edge $E^i_h$ and regular edge $E^r_h$, which are defined by

$$
E^i_h = \{ e \in E_h : e \cap \Gamma \neq \emptyset \}, \quad E^r_h = E_h \setminus E^i_h. \quad (2.6)
$$
For any interior edge $e$, there exist two triangles $T_{e,1}$ and $T_{e,2}$ such that $T_{e,1} \cap T_{e,2} = e$. Denote $n_e$ as the unit normal of $e$ pointing from $T_1$ to $T_2$, and define

$$\{u\} = \frac{1}{2} (u|_{T_{e,1}} + u|_{T_{e,2}}),$$  \hspace{1cm} (2.7)$$

$$[u] = u|_{T_{e,1}} - u|_{T_{e,2}}.$$  \hspace{1cm} (2.8)$$

When no confusion arises the subscript $e$ can be dropped. We also introduce two special function spaces $X_h$ and $X_{h,0}$ as

$$X_h := \{ v \in X_h : v|_T \in H^1(T), \ v \text{ is continuous at } N_h \text{ and across } \hat{E}_h \},$$  \hspace{1cm} (2.9)$$

$$X_{h,0} = \{ v \in X_h : v(z) = 0 \text{ for all } z \in N_h \cap \partial \Omega \}.$$  \hspace{1cm} (2.10)$$

We define a bilinear form $a_h : X_{h,0} \times X_{h,0} \to \mathbb{R}$ as

$$a_h(v, w) = \sum_{T \in \mathcal{T}_h} \int_T \beta \nabla v \cdot \nabla w \, dx - \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla v \cdot n_e \} [w] \, ds + \epsilon \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla w \cdot n_e \} [v] \, ds + \sum_{e \in \hat{E}_h} \sigma^0_e [v][w] \, ds,$$  \hspace{1cm} (2.11)$$

where the parameter $\sigma^0$ is positive and the parameter $\epsilon$ can be arbitrary. Usually, $\epsilon$ takes the value $-1, 0, \text{ or } 1$. It is easy to see that $a_h$ is symmetric if $\epsilon = -1$ and it is nonsymmetric otherwise.

The general variational form \[39\] of (2.1)–(2.5) is to find $u_h \in X_{h,0}$ such that

$$a_h(u, v) = (f, v), \ \forall v \in X_{h,0}.$$  \hspace{1cm} (2.12)$$

Fig. 2.1. Typical example of interface element.

2.2. Partially penalized immersed finite element method. The key idea of partially penalized immersed finite element (PPIFE) method \[39\] is to modify basis functions in interface elements to satisfy jump conditions (2.4) and (2.5). Consider a
typical interface element $T$ as in Figure 2.1 and let $z_4$ and $z_5$ be the intersection points between the interface $\Gamma$ and edges of the element. Connecting the line segment $z_4 z_5$ forms an approximation of interface $\Gamma$ in the element $T$, denoted by $\Gamma_h |_{T}$. Then the element $T$ is split into two parts: $T^-$ and $T^+$. We construct the following piecewise linear function on the interface element $T$

$$
\phi(z) = \begin{cases} 
\phi^+ = a^+ + b^+x + c^+y, & z = (x, y) \in T^+, \\
\phi^- = a^- + b^-x + c^-y, & z = (x, y) \in T^-,
\end{cases} \quad (2.13)
$$

where the coefficients are determined by the following linear system

$$
\phi(z_1) = V_1, \phi(z_2) = V_2, \phi(z_3) = V_3, \quad (2.14)
\phi^+(z_4) = \phi^-(z_4), \phi^+(z_5) = \phi^-(z_5), \beta^+ \partial_n \phi^+ = \beta^- \partial_n \phi^- \quad (2.15)
$$

with $V_i$ being the nodal variables. The immersed finite element space $V_h$ [36] is defined as

$$
V_h := \{ v \in V_h : v|_{T} \in V_h(T) \text{ and } v \text{ is continuous on } \mathcal{N}_h, \},
$$

$$
V_{h,0} = \{ v \in V_h : v(z) = 0 \text{ for all } z \in \mathcal{N}_h \cap \partial \Omega \},
$$

where

$$
V_h(T) := \begin{cases} 
\{ v|v \in P_1(T) \}, & \text{if } T \in T_h^e; \\
\{ v|v \text{ is defined by } (2.13) - (2.15) \}, & \text{if } T \in T_h^i.
\end{cases} \quad (2.18)
$$

A function in $V_h(T)$ is called a linear IFE function on $T$ when $T$ is an interface element. For the linear IFE function, traditional trace inequality [7,18] fails. In [39], Lin et al. established the following trace inequality:

**Lemma 2.1.** There exists a constant $C$ independent of the interface location such that for every linear IFE function $v$ on $T$, the following inequality holds:

$$
\| \beta \nabla \cdot n_e \|_{0,e} \leq Ch^{1/2}|T|^{-1/2} \sqrt{\beta} \| \nabla v \|_{0,K}. \quad (2.19)
$$

It is obvious that $V_h$ (resp. $V_{h,0}$) is a subspace of $X_h$ (resp. $X_{h,0}$). The PPIFE method for (2.1)–(2.5) reads as finding $u_h \in V_{h,0}$ such that

$$
a_h(u_h, v_h) = (f, v_h), \quad \forall v_h \in V_{h,0}. \quad (2.20)
$$

The energy norm $\| \cdot \|_h$ is defined as

$$
\| v_h \|_h = \left( \sum_{T \in T_h} \int_T \beta \nabla v_h \cdot \nabla v_h dx + \sum_{e \in E_h^i} \int_e \frac{\sigma^0}{|e|} [v_h]^2 ds \right)^{1/2}. \quad (2.21)
$$

The following coercivity has been proved in [39].

**Lemma 2.2.** There exists a constant $C > 0$ such that

$$
C \| v_h \|_h^2 \leq a_h(v_h, v_h), \quad \forall v_h \in V_{h,0}, \quad (2.22)
$$

is true for $\epsilon = 1$ unconditionally and is true for $\epsilon = 0$ or $\epsilon = -1$ under the condition that $\sigma^0_\epsilon$ is large enough.

Based on the above coercivity, Lin et al. proved the following optimal convergence result:
Theorem 2.3. Assume that the exact solution $u$ to the interface problem \([2.1]–[2.5]\) is in $H^3(\Omega^- \cup \Omega^+)$ and $u_h$ is the solution to \([2.20]\) on a Cartesian mesh $T_h$. Then there exists a constant $C$ such that

$$
\|u - u_h\|_h \leq C h \|u\|_{3, \Omega^- \cup \Omega^+}.
$$

(2.23)

Remark 2.1. As remarked in \([39]\), when the exact solution belongs to $W^{2, \infty}(\Omega^- \cup \Omega^+)$, the IFE solution $u_h$ of \([2.20]\) on a Cartesian mesh $T_h$ has error estimation in the following form

$$
\|u - u_h\|_h \leq C \left( h \|u\|_{3, \Omega^- \cup \Omega^+} + h^{3/2} \|u\|_{3, \infty, \Omega^- \cup \Omega^+} \right).
$$

(2.24)

Note that the above error estimation is also an optimal one since the leading (first) term is of $O(h)$.

3. Superconvergence Analysis. In this section, we first present a superconvergence analysis for the PPIFE method on shape regular meshes. Then we show that the gradient recovery method introduced in \([22]\) is applicable and prove that the recovered gradient is superconvergent to the exact gradient.

3.1. Superconclouseness result. From now on, we suppose $T_h$ is a shape regular triangular mesh although $T_h$ is usually Cartesian mesh in the literature of IFE methods. Let $h = \max_{T \in T_h} \text{diam}(T)$. The set of regular element $T_h^\prime$ can be further decomposed into the following two disjoint parts:

$$
T_h^- := \left\{ T \in T_h \mid T \text{ has all three vertices in } \Omega^- \right\},
$$

$$
T_h^+ := \left\{ T \in T_h \mid T \text{ has all three vertices in } \Omega^+ \right\}.
$$

(3.1)

Definition 3.1. 1. Two adjacent triangles are called to form an $O(h^{1+\alpha})$ approximate parallelogram if the lengths of any two opposite edges differ only by $O(h^{1+\alpha})$.

2. The triangulation $T_h$ is called to satisfy Condition $(\sigma, \alpha)$ if there exist a partition $T_{h,1} \cup T_{h,2}$ of $T_h$ and positive constants $\alpha$ and $\sigma$ such that every two adjacent triangles in $T_{h,1}$ form an $O(h^{1+\alpha})$ parallelogram and

$$
\sum_{T \in T_{h,2}} |T| = O(h^\sigma).
$$

Remark 3.1. It is obvious that Cartesian mesh satisfies Condition $(\sigma, \alpha)$ with $\sigma = \infty$ and $\alpha = 1$.

Suppose $T_h$ satisfies Condition $(\sigma, \alpha)$. Then we can prove the following superconclouseness result:

Theorem 3.2. Suppose the triangulation $T_h$ satisfies Condition $(\sigma, \alpha)$. Let $u$ be the solution of the interface problem \([2.1]–[2.5]\) and $u_I$ be the interpolation of $u$ in the IFE space $V_{h,0}$. If $u \in H^1(\Omega) \cap H^3(\Omega^- \cup \Omega^+) \cap W^{2, \infty}(\Omega^- \cup \Omega^+)$, then for all $v_h \in V_{h,0}$

$$
a_h(u - u_I, v_h) \leq C \left( h^{1+\rho} \|u\|_{3, \Omega^- \cup \Omega^+} + \|u\|_{2, \infty, \Omega^- \cup \Omega^+} \right) |v_h|_h.
$$

(3.2)

where $C$ is a constant independent of interface location and $h$ and $\rho = \min(\alpha, \frac{3}{2}, \frac{1}{2})$. 
Proof. Notice that

\[ a_h(u - u_I, v_h) = \sum_{T \in T_h} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx - \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \} \{ v_h \} \, ds + \]
\[ \epsilon \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla v_h \cdot n_e \} [u - u_I] \, ds + \sum_{e \in \hat{E}_h} \int_e \frac{\sigma_0}{|e|} [u - u_I] [v_h] \, ds \]
\[ = \sum_{T \in T_h^+} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx + \sum_{T \in T_h^-} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx \]
\[ \sum_{T \in T_h^+} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx - \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \} \{ v_h \} \, ds + \]
\[ \epsilon \sum_{e \in \hat{E}_h} \int_e \{ \beta \nabla v_h \cdot n_e \} [u - u_I] \, ds + \sum_{e \in \hat{E}_h} \int_e \frac{\sigma_0}{|e|} [u - u_I] [v_h] \, ds \]
\[ = I_1 + I_2 + I_3 + I_4 + I_5 + I_6. \] (3.3)

Since \( T_h \) satisfies Condition \((\sigma, \alpha)\), it follows that \( T_h^+ \) and \( T_h^- \) also satisfy Condition \((\sigma, \alpha)\). Using the fact that the IFE functions becoming standard linear function on regular element, we have the following estimates for \( I_1 \) and \( I_2 \), whose proof can be found in [48]:

\[ |I_1| \leq C h^{1+\rho} (\|u\|_{3,\Omega^+} + \|u\|_{2,\infty,\Omega^+}) |v_h|_h, \] (3.4)
\[ |I_2| \leq C h^{1+\rho} (\|u\|_{3,\Omega^-} + \|u\|_{2,\infty,\Omega^-}) |v_h|_h, \] (3.5)

where \( C \) is a constant independent of \( h \) and \( \rho = \min(\alpha, \frac{\sigma}{2}, \frac{1}{2}) \). Now we proceed to
where we have used (4.19) in [39]. To bound \( I_5 \), we estimate it. By the Cauchy-Schwartz inequality, we have

\[
I_5 = \sum_{T \in T_h} \int_T \beta \nabla (u - u_I) \cdot \nabla v_h \, dx
\]

\[
\leq \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla (u - u_I) \|_{0,T}^2 \right)^{1/2} \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla v_h \|_{0,T}^2 \right)^{1/2}
\]

\[
\leq C \left( \sum_{T \in T_h} h^2 \| u \|_{2,T^-}^2 \right)^{1/2} \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla v_h \|_{0,T}^2 \right)^{1/2}
\]

\[
\leq C \left( \sum_{T \in T_h} h^4 \| u \|_{2,\infty,T^-}^2 \right)^{1/2} \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla v_h \|_{0,T}^2 \right)^{1/2}
\]

\[
\leq Ch^2 \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \left( \sum_{T \in T_h} 1 \right)^{1/2} \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla v_h \|_{0,T}^2 \right)^{1/2}
\]

\[
\leq Ch^{3/2} \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \left( \sum_{T \in T_h} \| \beta^{1/2} \nabla v_h \|_{0,T}^2 \right)^{1/2}
\]

\[
\leq Ch^{3/2} \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \| v_h \|_h,
\]

where we have used optimal approximation capability of IFE space [35,36] and the fact that \( \sum_{T \in T_h} 1 \approx \mathcal{O}(h^{-1}) \). Then we estimate \( I_4 \). Cauchy-Schwartz inequality implies that

\[
I_4 = \sum_{e \in E_h} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \} [v_h] \, ds
\]

\[
\leq \left( \sum_{e \in E_h} \int_e \frac{|e|}{\sigma_0} \{ \beta \nabla (u - u_I) \cdot n_e \}^2 \, ds \right)^{1/2} \left( \sum_{e \in E_h} \int_e \frac{\sigma_0}{|e|} [v_h]^2 \, ds \right)^{1/2}
\]

\[
\leq Ch^{1/2} \left( \sum_{e \in E_h} \int_e \{ \beta \nabla (u - u_I) \cdot n_e \}^2 \, ds \right)^{1/2} \left( \sum_{e \in E_h} \int_e \frac{\sigma_0}{|e|} [v_h]^2 \, ds \right)^{1/2}
\]

\[
\leq Ch^2 \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \left( \sum_{T \in T_h} 1 \right)^{1/2} \left( \sum_{e \in E_h} \int_e \frac{\sigma_0}{|e|} [v_h]^2 \, ds \right)^{1/2}
\]

\[
\leq Ch^{3/2} \| u \|_{2,\infty,\Omega^- \cup \Omega^+} \| v_h \|_h,
\]

where we have used (4.19) in [39]. To bound \( I_5 \), we use the standard trace inequality.
Hence, we get (3.18) which implies
\[
\|u - u_I\|_{0,e} \leq \|(u - u_I)_{T_{e,1}}\|_{0,e} + \|(u - u_I)_{T_{e,2}}\|_{0,e} \\
\leq Ch^{-1/2}\left(\|u - u_I\|_{0,T_{e,1}} + h\|\nabla(u - u_I)\|_{0,T_{e,1}}\right) + Ch^{-1/2}\left(\|u - u_I\|_{0,T_{e,2}} + h\|\nabla(u - u_I)\|_{0,T_{e,2}}\right)
\]
\[
\leq Ch^{1/2}\left(\|u\|_{2,T_{e,1} \cup T_{e,2}^+} + \|u\|_{2,T_{e,2} \cup T_{e,1}^+}\right) \\
\leq Ch^{5/2}\|u\|_{2,\infty,\Omega - \partial \Omega^+}.
\]
Also, the trace inequality for IFE function (2.19) implies that
\[
\|\{\beta \nabla v_h \cdot n_e\}\|_{0,e} \leq \|\{\beta \nabla v_h|_{T_{e,1}} \cdot n_e\}\|_{0,e} + \|\{\beta \nabla v_h|_{T_{e,2}} \cdot n_e\}\|_{0,e} \\
\leq Ch^{-1/2}\left(\|\sqrt{\beta} \nabla v_h\|_{0,T_{e,1}} + \|\sqrt{\beta} \nabla v_h\|_{0,T_{e,2}}\right).
\]
Hence, we get
\[
I_5 = \left|\sum_{e \in \mathcal{E}_h^e} \int_e \{\beta \nabla v_h \cdot n_e\} [u - u_I] ds\right| \\
\leq \left(\sum_{e \in \mathcal{E}_h^e} \|\{\beta \nabla v_h \cdot n_e\}\|_{0,e}^2\right)^{1/2} \left(\sum_{e \in \mathcal{E}_h^e} \|u - u_I\|^2_{0,e}\right)^{1/2} \\
\leq C \left(\sum_{e \in \mathcal{E}_h^e} h^{-1}\left(\|\sqrt{\beta} \nabla v_h\|_{0,T_{e,1}} + \|\sqrt{\beta} \nabla v_h\|_{0,T_{e,2}}\right)^2\right)^{1/2} \left(\sum_{e \in \mathcal{E}_h^e} h^5\|u\|^2_{2,\infty,\Omega - \partial \Omega^+}\right)^{1/2} \\
\leq Ch^2\|u\|_{2,\infty,\Omega - \partial \Omega^+} \left(\sum_{T \in \mathcal{T}_h^e} \|\sqrt{\beta} \nabla v_h\|^2_{0,T}\right)^{1/2} \left(\sum_{T \in \mathcal{T}_h^e} 1\right)^{1/2} \\
\leq Ch^{3/2}\|u\|_{2,\infty,\Omega - \partial \Omega^+}\|v_h\|_h,
\]
where we have also used the fact \(\sum_{T \in \mathcal{T}_h^e} 1 \approx O(h^{-1})\). For \(I_6\), by the Cauchy-Schwartz inequality and (3.8), we have
\[
I_6 = \sum_{e \in \mathcal{E}_h^e} \left(\int_e \sigma_0^e[u - u_I][v_h] ds\right) \\
\leq \left(\sum_{e \in \mathcal{E}_h^e} \int_e \sigma_0^e[u - u_I]^2 ds\right)^{1/2} \left(\sum_{e \in \mathcal{E}_h^e} \int_e \sigma_0^e[v_h]^2 ds\right)^{1/2} \\
\leq Ch^{-1/2}\left(\sum_{e \in \mathcal{E}_h^e} \|u - u_I\|^2_{0,e}\right) \|v_h\|_h \\
\leq Ch^2\|u\|_{2,\infty,\Omega - \partial \Omega^+} \left(\sum_{T \in \mathcal{T}_h^e} 1\right)^{1/2} \|v_h\|_h \\
\leq Ch^{3/2}\|u\|_{2,\infty,\Omega - \partial \Omega^+}\|v_h\|_h,
\]
where we have also used the fact \( \sum_{T \in \mathcal{T}_h} 1 \approx \mathcal{O}(h^{-1}) \). Summarizing the bounds for \( I_i \) \((i = 1, 2, \cdots, 6)\) together gives \( \lVert u - u_l \rVert_h \leq C \left( h^{3/2} \| u \|_{2, \infty, \Omega + \cup \Omega^-} \right) \),

**Remark 3.2.** When the discontinuity disappears, \( \dot{E}_h^i \) will become empty. In that case, \( I_i \) \((i = 3, 4, 5, 6)\) will become zero and we can reproduce the standard supercloseness result \[48\].

**Remark 3.3.** Here we discuss the triangle element. For the bilinear PPIFE method, we can prove similar supercloseness results by adapting the integral identities in \[37,38\], the trace inequalities for bilinear IFE functions \[39\], and the same techniques that we used here to deal with the interface part.

Based on the supercloseness results, we can prove the following theorem:

**Theorem 3.3.** Assume the same hypothesis in Theorem 3.2 and let \( u_h \) be the IFE solution of discrete variational problem \( \lVert \nabla u - \nabla u_h \rVert_{\infty, \Omega + \cup \Omega^-} \leq \mathcal{O}(h) \); then

\[
\left\| u_h - u_l \right\|_h \leq C \left( h^{3/2} \| u \|_{2, \infty, \Omega + \cup \Omega^-} + h^{3/2} \| u \|_{2, \infty, \Omega + \cup \Omega^-} \right),
\]

where \( \rho = \min(\alpha, \frac{\pi}{2}, \frac{1}{2}) \).

**Proof.** Since \( V_{h,0} \) is a subset of \( X_{h,0} \), it follows that

\[
a_h(u - u_h, v_h) = 0, \quad \forall v_h \in V_{h,0}.
\]

Then we have

\[
a_h(u_h - u_l, v_h) = a_h(u - u_l, v_h), \quad \forall v_h \in V_{h,0}.
\]

Taking \( v_h = u_h - u_l \) and using Theorem 3.2 and Lemma 2.2, we prove \( 3.12 \). \( \square \)

**Remark 3.4.** Similarly as Remark 3.2, when the discontinuity disappear, \( 3.12 \) will reduce to the standard supercloseness result \[48\].

**3.2. Superconvergence results.** In this subsection, using the supercloseness results, we show that the recovered gradient of the PPIFE solution is superconvergent to the exact gradient.

To define the gradient recovery operator introduced \[22\], we first generate a local body-fitted mesh \( \hat{T}_h \) by adding some new vertices into \( \mathcal{N}_h \). Suppose \( \hat{X}_h \) is a \( C^0 \) linear finite element space defined on \( \hat{T}_h \), we defined an enrich operator \( \hat{E}_h : V_h \rightarrow \hat{X}_h \) by averaging the discontinuous values on interface vertices as in \[22\].

Let \( \Gamma_h \) be the approximated interface by connecting the intersection points of edges with \( \Gamma \). We can category the triangulation \( \hat{T}_h \) into the following two disjoint sets:

\[
\hat{T}_h^- := \left\{ T \in \mathcal{T}_h \text{ all three vertices of } T \text{ are in } \overline{\Omega^-} \right\},
\]

\[
\hat{T}_h^+ := \left\{ T \in \mathcal{T}_h \text{ all three vertices of } T \text{ are in } \overline{\Omega^+} \right\}.
\]

Let \( \Omega_h^- = \cup_{T \in \hat{T}_h^-} T \) and \( \Omega_h^+ = \cup_{T \in \hat{T}_h^+} T \). Suppose \( \hat{X}_h^- \) and \( \hat{X}_h^+ \) are the continuous linear finite element spaces defined on \( \hat{T}_h^- \) and \( \hat{T}_h^+ \), respectively.

Denote the PPR gradient recovery operator on \( \hat{X}_h^- \) by \( G_h^- \). Then \( G_h^- \) is a linear bounded operator from \( \hat{X}_h^- \) to \( \hat{X}_h^- \times \hat{X}_h^- \). Similarly, let \( G_h^+ \) be PPR gradient recovery operator from \( \hat{X}_h^+ \) to \( \hat{X}_h^+ \times \hat{X}_h^+ \). Then, for any \( u_h \in V_h \), let \( G_h : \hat{X}_h \rightarrow (\hat{X}_h^- \cup \hat{X}_h^+) \)}
\( \hat{X}^+ \times (\hat{X}^- \cup \hat{X}^+) \) be the immersed polynomial preserving recovery (IPPR) operator proposed in [21] which is defined as following,

\[
(G_h^I u_h)(z) = \begin{cases} 
(G_h^- u_h)(z) & \text{if } z \in \overline{\Omega_h^-}, \\
(G_h^+ u_h)(z) & \text{if } z \in \overline{\Omega_h^+}.
\end{cases}
\] (3.17)

Then the recovered gradient of PPIFE solution \( u_h \) is defined as

\[ R_h u_h = G_h^I(E_h u_h). \] (3.18)

The linear boundedness and consistency of the gradient recovery operator \( R_h \) are showed in [22]. The previous established supercloseness result enables us to prove the following main superconvergence result:

**Theorem 3.4.** Assume the same hypothesis in Theorem 3.2 and let \( u_h \) be the IFE solution of discrete variational problem (2.20) ; then

\[
\| \nabla u - R_h u_h \|_{0, \Omega} \leq C \left( h^{1+\rho} (\| u \|_{3, \Omega^+ \cup \Omega^-} + \| u \|_{2, \infty, \Omega^+ \cup \Omega^-}) + Ch^{3/2} \| u \|_{2, \infty, \Omega^+ \cup \Omega^-} \right).
\] (3.19)

**Proof.** We decompose \( \nabla u - R_h u_h \) as \( (\nabla u - R_h u_I) - (R_h u_I - R_h u_h) \). Then the triangle inequality implies that

\[
\| \nabla u - R_h u_h \|_{0, \Omega} \leq \| \nabla u - R_h u_I \|_{0, \Omega} + \| R_h u_I - R_h u_h \|_{0, \Omega} \leq: I_1 + I_2.
\] (3.20)

According to Theorem 3.7 in [22], we have

\[ I_1 \lesssim h^2 \| u \|_{3, \Omega^- \cup \Omega^+} \] (3.21)

Using definition (3.18), we obtain that

\[
I_2 = \| G_h E_h (u_I - u_h) \|_{0, \Omega} \\
\lesssim \| G_h E_h (u_I - u_h) \|_{0, \Omega^-} + \| G_h E_h (u_I - u_h) \|_{0, \Omega^+} \\
\lesssim \| \nabla E_h (u_I - u_h) \|_{0, \Omega^-} + \| \nabla E_h (u_I - u_h) \|_{0, \Omega^+} \\
\lesssim \| \nabla E_h (u_I - u_h) \|_{0, \Omega} \\
\lesssim \| \nabla (u_I - u_h) \|_{0, \Omega} \\
\lesssim h^{1+\rho} (\| u \|_{3, \Omega^+ \cup \Omega^-} + \| u \|_{2, \infty, \Omega^+ \cup \Omega^-}) + Ch^{3/2} \| u \|_{2, \infty, \Omega^+ \cup \Omega^-}
\] (3.22)

where we have used the boundedness property of \( G_h^\pm \) in the second inequality, Corollary 3.4 of [22] in the fourth inequality, and Theorem 3.3 in the last inequality. Combining (3.20) - (3.22) completes the proof of (3.19). \( \Box \)

The gradient recovery operator \( R_h \) naturally provides an \textit{a posteriori} error estimators for the PPIFE method. We define a local \textit{a posteriori} error estimator on element \( T \in T_h \) as

\[
\eta_T = \begin{cases} 
\| \beta^{1/2}(R_h u_h - \nabla u_h) \|_{0, T}, & \text{if } T \in T_h^r, \\
( \sum_{T \subset T, T \in \hat{T}_h} \| \beta^{1/2}(R_h u_h - \nabla u_h) \|_{0, T}^2 )^{1/2}, & \text{if } T \in T_h.
\end{cases}
\] (3.23)
and the corresponding global error estimator as

\[ \eta_h = \left( \sum_{T \in T_h} \eta_T^2 \right)^{1/2} \quad (3.24) \]

With the above superconvergence result, we are ready to prove the asymptotic exactness of error estimators based on the recovery operator \( R_h \).

**Theorem 3.5.** Assume the same hypothesis in Theorem 3.2 and let \( u_h \) be the IFE solution of discrete variational problem (2.20). Further assume that there is a constant \( C(u) > 0 \) such that

\[ \| \nabla (u - u_h) \|_{0, \Omega} \geq C(u)h. \quad (3.25) \]

Then it holds that

\[ \left| \frac{\eta_h}{\| \nabla (u - u_h) \|_{0, \Omega}} - 1 \right| \lesssim h^\rho. \quad (3.26) \]

**Proof.** It follows from Theorem 3.4, (3.25), and the triangle inequality. \( \square \)

**Remark 3.5.** Theorem 3.5 implies that (3.23) (or (3.24)) is an asymptotically exact a posteriori error estimator for PPIFE method.

**4. Numerical Examples.** In this section, the previous established supercloseness and superconvergence theory are demonstrated by three numerical examples. The first two are benchmark problems for testing numerical methods for linear interface problem. For that two examples, the computational domain are chosen as \( \Omega = [-1, 1] \times [-1, 1] \). The uniform triangulation of \( \Omega \) is obtained by dividing \( \Omega \) into \( N^2 \) sub-squares and then dividing each sub-square into two right triangles. The resulting uniform mesh size is \( h = 1/N \). The last example is a nonlinear interface problem. We test the examples using three different PPIFE method [39]: the symmetric PPIFE method (SPPIFEM), incomplete PPIFE method (IPPIFEM), and non-symmetric PPIFE method (NPPIFEM), which are corresponding to \( \epsilon = -1, \epsilon = 0, \) and \( \epsilon = 1 \), respectively. We choose the penalty parameter \( \sigma_0^e = \sqrt{\max(\beta^-, \beta^+)} \) for SPPIFEM and IPPIFEM and \( \sigma_0^e = 1 \) for NPPIFEM. For convenience, we shall adopt the following error norms in all the examples:

\[ D_e := \| u - u_h \|_{1, \Omega}, \quad D_i^e := \| \nabla u_I - \nabla u_h \|_{0, \Omega}, \quad D_r^e := \| \nabla u - R_h u_h \|_{0, \Omega}. \quad (4.1) \]

**Example 4.1.** In this example, we consider the elliptic interface problem (2.1) with a circular interface of radius \( r_0 = \frac{\pi}{6} \) as studied in [36]. The exact solution is

\[ u(z) = \begin{cases} \frac{x^3}{r^3} & \text{if } z \in \Omega_-, \\ \frac{x^3}{r^3} + \left( \frac{1}{r^3} - \frac{1}{r_0^3} \right) r_0^3 & \text{if } z \in \Omega^+, \end{cases} \]

where \( r = \sqrt{x^2 + y^2} \).

We use two typical jump ratios: \( \beta^- / \beta^+ = 1/10 \) and \( \beta^- / \beta^+ = 1/1000 \). Tables 4.1-4.6 report numerical results. For \( D_e \), all three partially penalized finite element methods converge with the optimal rate \( O(h) \) for both differential jump ratios. As for \( D_i^e \) and \( D_r^e \), \( O(h^{1.5}) \) order of convergence can be clearly observed for all cases, which support our Theorems 3.3 and 3.4.
Example 4.2. In this example, we consider the interface problem (2.1) with a
cardioid interface as in [27]. The interface curve $\Gamma$ is the zero level of the function
\[ \phi(x, y) = (3(x^2 + y^2) - x)^2 - x^2 - y^2, \]
as shown Figure 4.1. We choose the exact solution $u(x, y) = \phi(x, y)/\beta(x, y)$, where
\[ \beta(x, y) = \begin{cases} 
    xy + 3 & \text{if } (x, y) \in \Omega^-, \\
    100 & \text{if } (x, y) \in \Omega^+. 
\end{cases} \]

Note that the interface is not Lipschitz-continuous and has a singular point at the origin. Tables 4.7-4.9 display the numerical data. We observe the same supercloseness and superconvergence phenomena as predicted by our theory.

**Example 4.3.** In this example, we consider the following nonlinear interface problem
\[ -\nabla \cdot (\beta(z)\nabla u(z)) + \sin(u(z)) = f(z), \quad z \in \Omega \setminus \Gamma, \]

| $h$  | $D_e$ | order | $D^e$ | order | $D^e$ | order |
|------|-------|-------|-------|-------|-------|-------|
| 1/16 | 5.77e-02 | – | 5.71e-03 | – | 2.48e-02 | – |
| 1/32 | 3.03e-02 | 0.93 | 2.39e-03 | 1.26 | 7.88e-03 | 1.66 |
| 1/64 | 1.51e-02 | 1.01 | 8.55e-04 | 1.48 | 2.27e-03 | 1.80 |
| 1/128 | 7.43e-03 | 1.02 | 3.07e-04 | 1.48 | 7.10e-04 | 1.68 |
| 1/256 | 3.71e-03 | 1.00 | 1.34e-04 | 1.45 | 2.36e-04 | 1.59 |
| 1/512 | 1.86e-03 | 1.00 | 6.19e-05 | 1.52 | 8.84e-05 | 1.41 |
| 1/1024 | 9.32e-04 | 1.00 | 3.09e-05 | 1.50 | 3.08e-05 | 1.52 |
with homogeneous jump conditions (2.4) and (2.5) where \( \Omega = [-2, 2] \times [-2, 2] \setminus [-0.5, 0.5] \times [-0.5, 0.5] \). The interface curve \( \Gamma \) is circle centered at origin with radius \( r_0 = \pi/3 \). The exact solution is

\[
    u(z) = \begin{cases} 
        \frac{\log(r)}{\frac{1}{\beta} - 1}, & \text{if } z \in \Omega_-, \\
        \frac{\log(r)}{\frac{1}{\beta} - 1} + \left(\frac{1}{\beta} - \frac{1}{\beta^+}\right) \log(r_0), & \text{if } z \in \Omega^+,
    \end{cases}
\]

where \( r = |z| = \sqrt{x^2 + y^2} \). The right hand side function \( f \) and boundary condition are obtained from the exact solution.

The nonlinear interface problem is solved by the PPIFE method with Newton’s
iteration on a series of uniform meshes. The coarsest mesh is depicted in Fig. 4.2 and the finer meshes are obtained by the uniform refinement. Numerical results are reported in Tables 4.10-4.12. We observe the same superconvergence and supercloseness phenomena as linear problems.

5. Conclusion. In this paper, we study the superconvergence theory for partially penalized immersed finite element (PPIFE) method. Specifically, we obtain supercloseness results analogous to standard linear finite element method. Due to the existence of the interface, we can only prove a supercloseness result of order $O(h^{1.5})$. We also notice that the supercloseness result will reduce to the well known one for standard linear element when the discontinuity disappears. These results provide us a fundamental tool to prove the $O(h^{1.5})$ superconvergence of recovered gradient by using the gradient recovery operator proposed in [22]. We present three numerical examples to support our theoretical results.
