ON THE AUTOMORPHISM GROUPS OF REGULAR HYPER-STARS AND FOLDED HYPER-STARS

S. MORTEZA MIRAFZAL

ABSTRACT. The hyper-star graph $HS(n,k)$ is defined as follows: its vertex-set is the set of $\{0,1\}$-sequences of length $n$ with weight $k$, where the weight of a sequence $v$ is the number of 1's in $v$, and two vertices are adjacent if and only if one can be obtained from the other by exchanging the first symbol with a different symbol (1 with 0, or 0 with 1) in another position. In this paper, we will find the automorphism groups of regular hyper-star and folded hyper-star graphs. Then, we will show that, only the graphs $HS(4,2)$ and $FHS(4,2)$ are Cayley graphs.

Keywords: Vertex transitive graph; Permutation group; Symmetric graph; Cayley graph

AMS Subject Classifications: 05C25; 94C15

1. Introduction and Preliminaries

An interconnection network can be represented as an undirected graph where a processor is represented as a vertex and a communication channel between processors as an edge between corresponding vertices. Measures of the desirable properties for interconnection networks include degree, connectivity, scalability, diameter, fault tolerance, and symmetry [1]. For example in [4,6] have been found the symmetries of two important classes of graphs. The main aim of this paper is to study the symmetries of a class of graphs that are useful in some aspects for designing some interconnection networks. First major class of interconnection networks is the classical n-cubes. Star graphs were introduced by [1] as a competitive model to the n-cubes. Both the n-cubes and Star graphs have been studied and many
of the properties are known and star graphs have proven to be superior to the n-cubes. The hyper-star graphs were introduced in [8] as competitive model to both n-cubes and star graphs. Some of the structural and topological properties of hyper-star graphs have been studied in [3, 7]. For all the terminology and notation not defined here, we follow [2, 5, 10]. Let \( n > 2 \), the hyper-star graph \( HS(n, k) \) where, \( 1 \leq k \leq n - 1 \), is defined in [8] as follows: its vertex-set is the set of \( \{0, 1\} \)-sequences of length \( n \) with weight \( k \), where the weight of the sequence \( v \) is the number of 1's in \( v \), and two vertices are adjacent if and only if one can be obtained from the other by exchanging the first symbol with a different symbol (1 with 0 or 0 with 1) in another position. Formally, if we denote by \( V(HS(n, k)) \) and \( E(HS(n, k)) \) the vertex-set and edge-set of \( HS(n, k) \) respectively, then

\[
V = V(HS(n, k)) = \{x_1x_2\cdots x_n \mid x_i \in \{0, 1\}, \sum_{j=1}^{n} x_j = k\}
\]

\[
E = E(HS(n, k)) = \{\{u, v\} \mid u = x_1x_2\cdots x_n, v = x_ix_2\cdots x_{i-1}x_{i+1}\cdots x_n, x_1 = x_i^c\}, \text{ where } x^c \text{ is the complement of } x \text{ (} 0^c = 1 \text{ and } 1^c = 0 \text{).}
\]

It is clear that the degree of a vertex \( v \) of \( HS(n, k) \) is, \( n - k \) if \( 1 \in v \), or is \( k \) if \( 1 / \in v \). So \( HS(n, k) \) is regular if and only if \( n = 2k \).

Let \( X = \{1, 2, ..., n\} \) and \( X_k \) be the family of subsets of \( X \) with \( k \) elements. Let \( S(n, k) \) be the graph with vertex-set \( X_k \) and two vertices \( v = \{x_1, \cdots, x_k\} \) and \( w = \{y_1, \cdots, y_k\} \) are adjacent if and only if \( |v \cap w| = k - 1 \) and, 1 belongs to one, and only one, of the vertices \( v \) and \( w \), in other words \( w \) is obtained from \( v \) by replacing an element \( y \in X - v \) with 1, if \( 1 \in v \), and replacing \( x \in v \) by 1 if, \( 1 \notin v \). Let \( A \) be a subset of \( X \), then the characteristic function of \( A \) is the function \( \chi_A : X \rightarrow \{0, 1\} \) such that \( \chi_A(x) = 1 \), if and only if \( x \in A \). Thus \( A \rightarrow \chi_A \) is a bijection between the family of subsets of \( X \) and the set of sequences of \( \{0, 1\} \) of length \( n \). The graphs \( \Gamma_1 = (V_1, E_1) \) and \( \Gamma_2 = (V_2, E_2) \) are called isomorphic, if there is a bijection \( \alpha : V_1 \rightarrow V_2 \) such that, \( \{a, b\} \in E_1 \) if and only if \( \{\alpha(a), \alpha(b)\} \in E_2 \) for all \( a, b \in V_1 \). in such a case the bijection \( \alpha \) is called an isomorphism. Now it is an easy task to show that the graphs \( HS(n, k) \) and \( S(n, k) \) are isomorphic, in fact the correspondence \( A \rightarrow \chi_A \) is an isomorphism between \( S(n, k) \) and \( HS(n, k) \), and for this reason, from now
on, we work with $S(n,k)$ and we denote it by $HS(n,k)$. The following
figure shows the graph $HS(6,3)$, where the set $\{x,y,z\}$ is denoted by $xyz$.

![Fig. 1. HS(6,3) graph](image)

An automorphism of a graph $\Gamma$ is an isomorphism of $\Gamma$ with itself. The
set of all automorphisms of $\Gamma$, with the operation of composition of func-
tions, is a group, called the automorphism group of $\Gamma$ and denoted by $Aut(\Gamma)$. A permutation of a set is a bijection of it with itself. The group of
all permutations of a set $V$ is denoted by $Sym(V)$, or just $Sym(n)$ when $|V|=n$. A permutation group $G$ on $V$ is a subgroup of $Sym(V)$. In this
case we say that $G$ acts on $V$. If $\Gamma$ is a graph with vertex-set $V$, then we
can view each automorphism as a permutation of $V$, and so $Aut(\Gamma)$ is a
permutation group. Let $G$ act on $V$, we say that $G$ is transitive (or $G$ acts
transitively on $V$) if there is just one orbit. This means that given any
two elements $u$ and $v$ of $V$, there is an element $\beta$ of $G$ such that $\beta(u) = v$.

The graph $\Gamma$ is called vertex transitive if $Aut(\Gamma)$ acts transitively on
$V(\Gamma). The action of $Aut(\Gamma)$ on $V(\Gamma)$ induces an action on $E(\Gamma)$ by the
rule $\beta(x,y) = \{\beta(x), \beta(y)\}$, $\beta \in Aut(\Gamma)$, and $\Gamma$ is called edge transitive if
this action is transitive. The graph $\Gamma$ is called symmetric, if for all vertices
$u,v,x,y$, of $\Gamma$ such that $u$ and $v$ are adjacent, and $x$ and $y$ are adjacent,
there is an automorphism $\alpha$ such that $\alpha(u) = x$, and $\alpha(v) = y$. It is clear
that a symmetric graph is vertex transitive and edge transitive.

For $v \in V(\Gamma)$ and $G = Aut(\Gamma)$, the stabilizer subgroup $G_v$ is the sub-
group of $G$ containing all automorphisms which fix $v$. In the vertex transi-
tive case all stabilizer subgroups $G_v$ are conjugate in $G$, and consequently
isomorphic, in this case, the index of $G_v$ in $G$ is given by the equation,

$$|G : G_v| = \frac{|G|}{|G_v|} = |V(\Gamma)|.$$ If each stabilizer $G_v$ is the identity group, then

every element of $G$, except the identity, does not fix any vertex, and we say

that $G$ acts semiregularly on $V$. We say that $G$ acts regularly on $V$ if and

only if $G$ acts transitively and semiregularly on $V$ and in this case we have

$$|V| = |G|.$$

Let $G$ be any abstract finite group with identity $1$, and suppose that $\Omega$

is a set of generators of $G$, with the properties :

(i) $x \in \Omega \implies x^{-1} \in \Omega$; (ii) $1 \notin \Omega$ ;

The Cayley graph $\Gamma = \Gamma(G, \Omega)$ is the ( simple ) graph whose vertex-set

and edge-set defined as follows :

$V(\Gamma) = G; E(\Gamma) = \{ \{g, h\} \mid g^{-1}h \in \Omega \}$. It can be shown that a con-

nected graph $\Gamma$ is a cayley graph if and only if $\text{Aut}(\Gamma)$ contains a subgroup $H$,

such that $H$ acts regularly on $V(\Gamma) [2, 5]$.

The group $G$ is called a semidirect product of $N$ by $Q$, denoted by

$G = N \ltimes Q$, if $G$ contains subgroups $N$ and $Q$ such that, (i) $N \leq G$ ($N$ is a

normal subgroup of $G$ ); (ii) $NQ = G$; (iii) $N \cap Q = 1$.

2. Main results

In the remaining of this section we assume that $k$ is a fixed natural

number, but arbitrarily chosen and $k > 2$ and $X = \{1, 2, ..., 2k\}$.

Lemma 2.1. The graph $HS(2k, k)$ is a vertex transitive graph.

Proof. In [8] it is proved that $HS(2k, k)$ is a vertex transitive graph and

in [3] it is proved that this graph is edge transitive, but for the sake of consistency and,

since our proof is independent of those and we need our proof in the sequel, we bring a proof. Let $V = V(HS(2k, k))$. The graph

$HS(2k, k)$ is a regular bipartite graph of valency (regularity $k$ ), in fact

if $P_1 = \{v \in V \mid 1 \in v\}$ and $P_2 = \{w \in V \mid 1 \notin w\}$ then, $\{P_1, P_2\}$

is a partition of $V$ and every edge of $HS(2k, k)$ has a vertex in $P_1$ and

a vertex in $P_2$ and $|P_1| = |P_2|$. Let $\alpha$ be a permutation of $\text{Sym}(X)$

such that $\alpha$ fixes the element $1$. $\alpha$ induces a permutation $\tilde{\alpha}$ on $V$ by the

rule $\tilde{\alpha}(\{x_1, x_2, \cdots, x_k\}) = \{\alpha(x_1), \alpha(x_2), \cdots, \alpha(x_k)\}$. We have $|v \cap w| =
Now let $v$ be transitive graph, it is enough to show that $G$ is an automorphism of $HS(2k,k)$. Note that if $v \in P_1$, then $\alpha(v) \in P_1$, thus $\alpha(P_1) = P_1$ and $\alpha(P_2) = P_2$. For any vertex $v$ in $V$, let $v^c$ be the complement of the set $v$ in $X$. We define the mapping $\theta : V \to V$ by the rule, $\theta(v) = v^c$, for every $v$ in $V$. In fact $\theta$ is an automorphism of $HS(2k,k)$. Note that for any $\alpha$ in $Sym(X)$ that fixes $1$, $\alpha \neq \theta$. Now, let $v, w \in V$. Suppose $v, w \in P_1$ and $|v \cap w| = t$. Let $v = \{1, x_2, ..., x_t, y_1, ..., y_{k-1}\}$ and $w = \{1, x_2, ..., x_t, z_1, ..., z_{k-1}\}$. We define the permutation $\pi \in Sym(X)$ by the rule: $\pi(1) = 1, \pi(x_i) = x_i, \pi(y_j) = z_j$, and $\pi(u) = u, u \in X - (v \cup w)$. Thus, $\hat{\pi}$ is an automorphism of $HS(2k,k)$ and $\hat{\pi}(v) = w$. If $v, w \in P_2$ then, $\theta(v), \theta(w) \in P_1$, therefore there is an automorphism $\hat{\pi}$ in $Aut(HS(2k,k))$ such that $\hat{\pi}(\theta(v)) = \theta(w)$, thus $\hat{\pi}(\theta^{-1} \theta(v)) = w$. Now, let $v \in P_1$ and $w \in P_2$, thus $\theta(w) \in P_1$ and there is an automorphism $\hat{\pi} \in Aut(HS(2k,k))$ such that $\hat{\pi}(v) = \theta(w)$, then we have $\theta^{-1} \hat{\pi}(v) = w$.

For a graph $\Gamma$ and $v \in V(\Gamma)$, let $N(v)$ be the set of vertices $w$ of $\Gamma$ such that $w$ is adjacent to $v$. If $G = Aut(\Gamma)$, then $G_v$ acts on $N(v)$, if we restrict the domains of the permutations $g \in G_v$ to $N(v)$. It is an easy task to show that a vertex transitive graph $\Gamma$ is symmetric, if and only if, $G_v$ acts transitively on the set $N(v)$ for any $v \in V(\Gamma)$. In the sequel $\theta$ is the automorphism of $HS(2k,k)$ which is defined in Lemma 2.1.

**Theorem 2.2.** The graph $HS(2k,k)$ is a symmetric graph.

**Proof.** Let $\Gamma = HS(2k,k)$ and $G = Aut(HS(2k,k))$. Since $\Gamma$ is a vertex transitive graph, it is enough to show that $G_v$ acts transitively on $N(v)$ for any $v \in V = V(\Gamma)$. Let $v \in P_1$, $v = \{1, x_2, ..., x_k\}$, thus $N(v) = \{y_i, x_2, ..., x_k\}$, where $X = \{1, x_2, ..., x_k, y_1, ..., y_k\}$. If $w_i, w_j \in N(v)$, $w_i = \{y_i, x_2, ..., x_k\}$, $w_j = \{y_j, x_2, ..., x_k\}$, then the transposition $\tau = (y_i y_j) \in Sym(X)$ is such that $\hat{\tau}$ is in $G_v$ and $\hat{\tau}(w_i) = w_j$. Now let $v \in P_2$ and $u, w \in N(v)$, thus $\theta(v) = v^c \in P_1$ and $\theta(u), \theta(w) \in N(\theta(v)) = N(v^c)$. Therefore there is an automorphism $\pi \in G_{v^c}$ such that
\[ \pi(\theta(u)) = \theta(v). \] Thus, \((\theta^{-1} \pi \theta)(u) = w\) and since \(\pi(\theta(v)) = \theta(v)\), we have \((\theta^{-1} \pi \theta)(v) = v\). 

Suppose \(\Gamma\) is a graph and \(G = \text{Aut}(\Gamma)\). For a vertex \(v\) of \(\Gamma\), let \(L_v\) be the set of all elements \(g\) of \(G_v\) such that \(g\) fixes each element of \(N(v)\). Let \(L_{v,w} = L_v \cap L_w\).

**Lemma 2.3.** Let \(\Gamma\) be a graph such that every vertex of it is of degree greater than one and \(G = \text{Aut}(\Gamma)\). If \(v\) be a vertex of \(\Gamma\) of degree \(b\), and \(w\) be an element of \(N(v)\) with minimum degree \(m\), then, \(|G_v| \leq b!(m-1)!|L_{vw}|\).

**Proof.** Let \(Y = N(v)\) and \(\Phi : G_v \rightarrow \text{Sym}(Y)\) be defined by the rule, \(\Phi(g) = g|_Y\) for any element \(g\) in \(G_v\), where \(g|_Y\) is the restriction of \(g\) to \(Y\). In fact \(\Phi\) is a group homomorphism and \(\text{ker}(\Phi) = L_v\), thus \(G_v/L_v\) is isomorphic with a subgroup of \(\text{Sym}(Y)\). Since, \(|Y| = \text{deg}(v) = b\), therefore \(|G_v|/|L_v| \leq b!\).

Now, \(|G_v| \leq (b!)/|L_v|\). If \(w\) is an element of \(N(v)\) of degree \(l\) and \(g \in L_v\), then \(g\) fixes \(v \in N(w)\). Let \(Z = N(w) - \{v\}\) and \(\Psi : L_v \rightarrow \text{Sym}(Z)\) be defined by \(\Psi(h) = h|_Z\), for any element \(h\) in \(L_v\). Then the kernel of the homomorphism \(\Psi\) is \(L_{vw}\) and since \(|Z| = l - 1\), thus \(|L_v| \leq (l-1)!|L_{v,w}|\).

Now, we have \(|G_v| \leq b!(l-1)!|L_{v,w}|\). If \(w\) be an element in \(N(v)\) of minimum degree \(m\), then the result follows.

\[\square\]

From the previous Lemma it follows that, if \(\Gamma\) is a regular graph of degree \(m\), then for every edge \(\{v,w\}\) of \(\Gamma\) we have \(|G_v| \leq m!(m-1)!|L_{vw}|\).

**Theorem 2.4.** The automorphism group of \(HS(2k,k)\) is a semidirect product of \(N\) by \(Q\), where \(N\) is isomorphic to \(\text{Sym}(2k-1)\) and \(Q\) is isomorphic to \(Z_2\), the cyclic group of order 2.

**Proof.** If \(H\) be the subgroup of \(\text{Sym}(X)\) that contains permutations which fix the element 1, then \(H\) is isomorphic with \(\text{Sym}(2k-1)\). Then \(f : H \rightarrow \text{Aut}(HS(2k,k)) = G\), defined by \(f(\alpha) = \tilde{\alpha}\), (\(\tilde{\alpha}\) is defined in Lemma 2.1) is an injection. In fact, if \(\alpha \neq 1\) be in \(\text{Sym}(X)\) and \(\alpha(1) = 1\), then there is an \(x \in X\) such that \(\alpha(x) \neq x\). Now, let \(T\) be a \(k\)-subset of \(X\) such that \(x \in T\).
and \( \alpha(x) \notin T \). Then \( \hat{\alpha}(T) \neq T \) and hence \( \hat{\alpha} \neq 1 \). It follows that the kernel of the homomorphism \( f \) is the identity group. Therefore, the subgroup \( f(H) = N = \{ \hat{\alpha} | \alpha \in H \} \) is of order \((2k-1)!\). If \( Q \) be the cyclic subgroup of \( G \) generated by \( \theta \) (\( \theta \) is defined in Lemma 2.1), then \( |Q| = 2 \). Since, \( \theta \notin N \), so \( N \cap Q = 1 \), thus for the set \( NQ \subseteq G \) we have \( |NQ| = \frac{|N||Q|}{|N \cap Q|} = (2k - 1)!/(2) \), so we have \( |G| \geq (2k - 1)!/(2) \). If we show that \( |G| \leq (2k - 1)!/(2) \), then we must have \( G = NQ \) and since the index of \( N \) in \( NQ = G \) is 2, then \( N \) is a normal subgroup of \( G \) and the theorem will be proved. In the first step of the remaining proof, we assert that every 3-path in the graph \( \Gamma = HS(2k, k) \) determines a unique 6-cycle in this graph. Let \( P : v_1v_2v_3v_4 \) be a 3-path in \( \Gamma \). The path \( P \) has a form such as, \( v_1 = \{y_1, x_2, x_3, \ldots x_k\}v_2 = \{1, x_2, x_3, \ldots x_k\}v_3 = \{y_2, x_2, x_3, \ldots x_k\}v_4 = \{y_2, 1, x_3, \ldots x_k\} \). If \( C \) be a 6-cycle of \( \Gamma \) that contains \( P \), then \( C \) has two adjacent vertices \( v_5 \) and \( v_6 \) such that \( v_5 \) is adjacent to \( v_4 \) and \( v_6 \) is adjacent to \( v_1 \). Thus \( v_5 \) has a form such as \( v_5 = \{y_2, s, x_3, \ldots x_k\} \) where, \( s \in \{y_1, y_3, \ldots y_k, x_1\} \) and \( v_6 \) has a form such as \( v_6 = \{y_1, x_2, \ldots x_{i-1}, 1, x_{i+1}, \ldots x_k\} \). Since \( v_5 \) and \( v_6 \) are adjacent we must have \( v_5 = \{y_2, y_1, x_3, \ldots x_k\} \) and \( v_6 = \{y_1, 1, x_3, \ldots x_k\} \). Now the assertion is proved. In the second step we show that if \( \{v,w\} \) be an edge of \( \Gamma \), then \( L_{v,w} = 1 \). Let \( g \in L_{v,w} \) and \( x \) be a vertex of \( \Gamma \) of distance 2 from \( v \). If \( x \) is adjacent to \( w \), then \( g(x) = x \). Let \( x \) is not adjacent to \( w \), so there is a vertex \( y \) adjacent to \( v \) such that \( vyx \) is a 2-path of \( \Gamma \). If \( C : xyvwtu \) be the unique 6-cycle that contains the 3-path \( xyuv \), then \( g(C) \) is the 6-cycle \( g(x)yvwtg(u) \), so \( C \) and \( g(C) \) contain the 3-path \( yvwt \), thus \( g(C) = C \). Therefore \( g_{|V(C)} \) is an automorphism of 6-cycle \( C \) that fixes the 2-path \( vyuv \), thus \( g \) fixes all vertices of this cycle and we have \( g(x) = x \). Now, since the graph \( \Gamma \) is connected, it follows that \( g \) fixes all the vertices of \( \Gamma \), so \( g = 1 \) and \( L_{v,w} = 1 \).

The graph \( \Gamma \) is vertex transitive, thus for a vertex \( v \in V = V(\Gamma) \) we have:

\[
|G| = |V||G_v| \leq \binom{2k}{k}(k!)(k-1)! = \frac{2k!}{k!}k!(k-1)! = \frac{2k!}{k} = (2k-1)!2
\]  

\[\square\]
Remark: As we can see in the proof of Theorem 2.4, the graph $HS(2k, k)$ has 6-cycles and since this graph is bipartite, hence it has no 3-cycles and no 5-cycles. It is easy to show that this graph has no 4-cycles, so the girth of this graph is 6.

3. Folded hyper-star graphs

The folded hyper star-graph $FHS(2k, k)$ is the graph which its vertex-set is identical to the vertex-set of hyper-star graph $HS(2k, k)$, and with edge-set $E_2 = E_1 \cup \{\{v, v^c\} \mid v \in V_1\}$, where $E_1$ and $V_1$ are the edge-set and vertex-set of $HS(2k, k)$ respectively. It is clear that this graph is a regular bipartite graph of degree $k + 1$. It is an easy task to show that the diameter of $FHS(2k, k)$ is $k$, whereas the diameter of $HS(2k, k)$ is $2k - 1$ [8]. We will show that this graph is also vertex transitive, thus its edge connectivity is maximum, say $k+1$ [5, 11]. Let $v$ be a vertex of $FHS(2k, k)$. We can suppose that $v = \{1, x_2, ..., x_k\}$, then $N(v) = \{\{y_i, x_2, ..., x_k\}, 1 \leq i \leq k\} \cup \{\{y_1, ..., y_k\}\}$, where $X = \{1, x_2, ..., x_k, y_1, ..., y_k\}$. Then for every $w \in N(v)$ and $w \neq v^c$, $w^c$ is the unique vertex that is in $N(v^c)$ and adjacent to $w$. Thus, if $\{v, w\}$ be an edge of this graph and $v \neq w^c$, then the 4-cycle $vww^c$ is the unique 4-cycle that contains this edge, whereas if $w = v^c$, then any 4-cycle $vww^c$ contains this edge. Let $uvw^c$ be a 3-path in $FHS(2k, k)$ and $u \neq w^c$, then by a similar way that we have seen in the proof of Theorem 2.4, we can show that the 6-cycle $uvw^c$ is the unique 6-cycle that contains this 3-path. It is clear that the girth of this graph is 4. The following figure shows $HS(4, 2)$ graph and $FHS(4, 2)$ graph.

![Fig. 2. FHS(4,2) graph](image-url)
Theorem 3.1. The automorphism group of folded hyper-star graph $FHS(2k,k)$ is identical to the automorphism group of hyper-star graph $HS(2k,k)$.

Proof. Let $\Gamma_1 = HS(2k,k)$, $\Gamma_2 = FHS(2k,k)$ and $H = NQ$ be the set which is defined in the proof of Theorem 2.4. Let $\{v,w\} = e$ be an edge of $\Gamma_2$ and $h \in NQ$. If $e$ be an edge of $\Gamma_1$, then $h(e)$ is an edge of $\Gamma_2$. If $e$ is not an edge of $\Gamma_1$, then $w = v^e$. Let $h = nq$, $n \in N$, $q \in Q$, then we have $h(e) = \{h(v), h(v^e)\} = \{nq(v), nq(v^e)\} = \{n(v), n(v^e)\}$, now since, $|n(v) \cap n(v^e)| = |v \cap v^e| = 0$, then $h(e)$ is an edge of the graph $\Gamma_2$. It follows that $H = NQ \leq Aut(\Gamma_2)$. Then $|Aut(\Gamma_2)| \geq |NQ| = (2k - 1)!2$.

Let $G = Aut(\Gamma_2)$. If $\{v,w\}$ be an edge of $\Gamma_2$ such that $w \neq v^e$, then we will show that $L_{v,w} = 1$. Let $u \in L_{v,w}$. Let $u$ be a vertex of $\Gamma_2$ of distance 2 from the vertex $v$. Then there is a vertex $t$ such that $utv$ is a 2-path in the graph $\Gamma_2$. If $t = v^e$, then the 4-cycle, $C : uv^evu^e$ is the unique 4-cycle that contains the 2-path $v^evu^e$. On the other hand, the 4-cycle $g(C) = g(u)v^evu^e$ also contains this 2-path, hence $g(u) = u$. Suppose that $t \neq v^e, u^e$, then the path $utvw$ is a 3-path in the subgraph $\Gamma_1 = HS(2k,k)$, so there is a unique 6-cycle $C : uv^ew^e$ in $\Gamma_1$ that contains this 3-path. $C$ also is the unique 6-cycle in $\Gamma_2$ that contains the 3-path $utvw$. On the other hand, $g(C) = g(u)g(t)g(v)g(w)g(r)g(s) = g(u)tvwr(s)$, thus $g(C)$ and $C$ are 6-cycles that contains the 3-path $tvwr$, hence $g(C) = C$ and $g|_V(C)$, the restriction of $g$ to $V(C)$, is an automorphism of the cycle $C$ that fixes the vertices $t,v,w,r$, therefore $g(u) = u$. If $u = t^e$, then $C : vt^e v^e$ is the unique 4-cycle that contains the 2-path $v^ev^e$ and $g(C) : vtg(t^e)v^e$ also contains this 2-path, so $g(C) = C$, then $g(u) = u$.

Since the graph $\Gamma_2$ is a connected graph, thus we can conclude that $g(u) = u$ for any vertex $u$ of $\Gamma_2$, then $L_{v,w} = 1$.

Let $v$ be a vertex of $\Gamma_2$, since this graph is a regular graph of degree $k + 1$, then from Lemma 2.3, it follows that $|G_v| \leq (k + 1)!k!$. Now, We show that in fact, $|G_v| \leq (k - 1)!k!$. Let $v$ be a vertex of $\Gamma_2$, $w \in N(v)$ and $w \neq v^e$. If $g \in L_v$, then $g$ fixes $w$, so $g$ induces a permutation on $N(w)$. Since, the 4-cycles $C : wvv^ew^e$ and $g(C) = wvv^eg(w^e)$, are identical, then
Therefore $g$ fixes two elements $v$ and $w^c$ of $N(w)$, hence $L_v/L_{ow} \leq \text{Sym}(k + 1 - 2)$, thus $|L_v| \leq (k - 1)!$. Now, let $h \in G_v$, then $h$ induces a permutation on $N(v)$, so $h(v^c) = w$ is in $N(v)$. Let $B = N(v) \cup N(v^c) - \{v, v^c\}$ and $S[B] = T$ be the subgraph induced by $B$. It is clear that $T$ is isomorphic to $h(T)$, where $h(T)$ is the subgraph induced by the set $D = h(B) = N(v) \cup N(w) - \{v, w\}$. We assert that if $w \neq v^c$, then the subgraph induced by $D$ has not any edge, whereas the subgraph induced by $B$ has $k$ edges. Suppose $x, y \in D$ and $x \in N(v)$ and $y \in N(w)$. We can assume that $v = \{1, x_2, \ldots, x_k\}$ and $w = \{y_1, x_2, \ldots, x_k\}$, then $x = \{y_j, x_2, \ldots, x_k\}$ and $y = \{y_i, x_2, \ldots, x_k\}$, where $i \neq j$. Now, it is clear that $\{x, y\}$ is not an edge of $\Gamma_2$. Hence, $h(v^c) = w = v^c$.

Now if $Y = N(v) - \{v^c\}$, then $h|_Y \in \text{Sym}(Y)$, so $G_v/L_v \leq \text{Sym}(k)$, therefore $|G_v| \leq |L_v| \times (k!) = (k - 1)!k!$. Since The graph $\Gamma_2$ is a vertex transitive graph, thus;

$$|Aut(\Gamma_2)| = |G| = |V(\Gamma_2)| \times |G_v| \leq \frac{2k!}{k!k!}(k - 1)! = (2k - 1)!2$$

Now, we have $Aut(FHS(2k, k)) = H = NQ = Aut(HS(2k, k))$.

If $k = 2$, then $HS(2k, k)$ is isomorphic to $C_6$, the cycle on 6 vertices, hence $Aut(HS(4, 2))$ is $D_{12}$, the dihedral group of order 12. If $m$ be an odd number, then $D_{4m} = D_{2m} \times Z_2$. Therefore $D_{12} = D_6 \times Z_2$, but $D_6 \cong \text{Sym}(3)$, hence Theorem 2.4 is also true for $k = 2$. But $FHS(4, 2)$ is isomorphic to $K_{3,3}$, the complete bipartite graph of degree 3, and $Aut(K_{3,3})$ is a group of order 72 [2], thus Theorem 3.1 is not true for $k = 2$.

The group $G$ acting on a set $\Omega$ induces a natural action on the set $\Omega^{(m)}$, the set of $m$-element subsets of $\Omega$, by the rule $A^g = \{a_1, \ldots, a_m\}^g = \{g(a_1), \ldots, g(a_m)\}$, where $A \subseteq \Omega$ and $g \in G$. The group $G$ is called $m$-homogenous, if its action on $\Omega^{(m)}$ is transitive. We need the following fact.

**FACT** [9]. Let $G$ be a group acting on a set $\Omega$, and $|\Omega| = n \geq 2m$, $m \geq 2$. If $G$ is $m$-homogenous, then it is also $(m-1)$-homogenous.
Theorem 3.2. Let $k \geq 3$. If $\Gamma \in \{ HS(2k, k), FHS(2k, k) \}$, then $\Gamma$ is not a Cayley graph.

Proof. We know that $Aut(HS(2k, k)) = Aut(FHS(2k, k))$, so if $R$ is a subgroup of $Aut(HS(2k, k))$, then $R$ acts regularly on $V(HS(2k, k))$ if and only if $R$ acts regularly on $V(FHS(2k, k))$. Hence, it is enough to prove the theorem for $HS(2k, k)$. Suppose the contrary, that $HS(2k, k)$ is a Cayley graph, then $Aut(HS(2k, k))$ has a subgroup $R$ that acts regularly on $V(HS(2k, k))$, then $|R| = \binom{2k}{k} = \frac{2k!}{k!k!}$. If $r$ is an element of $R$, then $r = \tilde{\sigma}\theta^i$, where $\tilde{\sigma}$ and $\theta$ are defined in the proof of Theorem 2.4 and $i \in \{0,1\}$. Let $M_1 = \{\tilde{\sigma} | \tilde{\sigma} \in R\}$, then $M_1$ is a subgroup of $R$. Since $R$ acts on $V(HS(2k, k))$ transitively, so $R$ contains an element of the form $\tilde{\sigma}\theta$. Now, if $M_2 = \{\tilde{\sigma}\theta | \tilde{\sigma} \in R\}$, then $M_2\tilde{\sigma}\theta \subseteq M_1$, because $\tilde{\sigma}\theta\tilde{\sigma}\theta = \tilde{\sigma}\tilde{\gamma}$. Then, $|M_2| \leq |M_1|$. Since $M_1\tilde{\sigma}\theta \subseteq M_2$, then $|M_1| \leq |M_2|$, so $|M_1| = |M_2| = (1/2)R$. If $M = \{\sigma | \sigma \in M_1\}$, then $|M_1| = |M|$ and $M$ is a subgroup of $Sym(X)$ and every element of $M$ fixes the element 1, where $X = \{1,2,...,2k\}$. In fact $M$ acts on $Y = \{2,...,2k\}$ and is $(k-1)$-homogenous on this set. Since $2(k-1) \leq 2k-1$, then $M$ is $(k-2)$-homogenous on $Y$. Hence we must have, $\binom{2k-1}{k-2} | M = (1/2)\binom{2k}{k}$, therefore $2(2k-1)!k!k! | (2k!(k-2)!(k+1)!$, hence $k(k-1) | k(k+1)$, so $k-1 | k+1$, thus we must have $k \in \{1,2,3\}$. If $k = 3$, then $|M| = (1/2)\binom{6}{3} = 10$. Since $2 | |M|$, then there is an element $\sigma$ in $M$ such that the order of $\sigma$ is 2. Note that $\sigma$ is an element of $Sym(6)$ that fixes 1. If we write $\sigma$ in the form of a product of disjoint cycles, then $\sigma = (rs)$ or $\sigma = (rs)(tu)$, where $r,s,t,u \in \{2,3,...,6\}$. In each of these cases, for $\tilde{\sigma} \in R$ and vertex $v = \{1,r,s\}$ of $HS(6,3)$ we have $\tilde{\sigma}(v) = \{\sigma(1), \sigma(r), \sigma(s)\} = \{1,r,s\} = v$. Thus $R$ can not be a regular subgroup of $Aut(HS(6,3))$ which contradicts the assumption.

If $k = 2$, then $HS(4,2)$ is $C_6$, the cycle on 6 vertices, which is the Cayley graph $\Gamma = \Gamma(Z_6, \Omega)$, where $Z_6$ is the cyclic group of order 6 and $\Omega = \{1,-1\}$. The graph $FHS(4,2)$ is $K_{3,3}$, the complete bipartite graph of degree 3, which is the Cayley graph $\Gamma = \Gamma(Sym(3), \Omega)$, where $\Omega = \{(12), (23), (13)\}$ [2].
