GROUND STATES ARE GENERICALLY A PERIODIC ORBIT

GONZALO CONTRERAS

Abstract. We prove that for an expanding transformation the maximizing measures of a generic Lipschitz function are supported on a single periodic orbit.

1. Introduction

Let \( X \) be a compact metric space and \( T : X \to X \) an expanding map. This means that there are numbers \( d \in \mathbb{Z}^+, 0 < \lambda < 1 \) such that for every point \( x \in X \) there is a neighborhood \( U_x \) of \( x \) in \( X \) and continuous branches \( S_i, i = 1, \ldots, \ell_x \leq d \) of the inverse of \( T \) such that
\[
T^{-1}(U_x) = \bigcup_{i=1}^{\ell_x} S_i(U_x), \quad T \circ S_i = I_{U_x} \quad \forall i,
\]
and
\[
d(S_i(y), S_i(z)) \leq \lambda d(y, z) \quad \forall y, z \in U_x.
\]

Given a continuous function \( F : X \to \mathbb{R} \), a maximizing measure is a \( T \)-invariant Borel probability measure \( \mu \) which maximizes the integral of \( F \) among all \( T \)-invariant Borel probabilities:
\[
\int F \, d\mu = \sup \left\{ \int F \, d\nu \mid \nu \in \mathcal{M}(T) \right\},
\]
where
\[
\mathcal{M}(T) = \{ \text{\( T \)-invariant Borel probabilities in } X \}.
\]

Recall that an equilibrium state for \( F \) is an invariant Borel probability \( \mu_F \) which satisfies
\[
\mu_F := \arg \max \left\{ h_{\mu}(T) + \int F \, d\mu \mid \mu \in \mathcal{M}(T) \right\}.
\]

Ground states are the zero temperature limits of equilibrium states. This is, limits of the form \( \lim_{\beta \to +\infty} \mu_{\beta F} \). Here \( \beta \) is interpreted as the inverse of the temperature. It is known [9, Proposition 29] that if the limit of a sequence \( \{\mu_{\beta_k F}\}_k \) with \( \beta_k \to \infty \) exists, then it has to be a maximizing measure with maximal entropy among the maximizing measures. Brémont [4] proves that the limit \( \lim_{\beta \to +\infty} \mu_{\beta F} \) exists if \( F \) is locally constant. Chazottes, Gambaudo and Ugalde [7] give a characterization of the limit and a new proof of Brémont’s

---

Gonzalo Contreras was Partially supported by CONACYT, Mexico, grant 178838.
result. Leplaideur [14] gives another proof of Brémond’s theorem and a generalization: if \( G \) is Hölder continuous and \( F \) is locally constant, when \( \beta \to \infty \) the limit of the equilibrium states of \( G + \beta F \) exists. Chazottes and Hochman [8] give an example of a Lipschitz function \( F \) for which the zero temperature limit does not exist\(^1\).

For generic Hölder or Lipschitz functions \( F \), the maximizing measure is unique. This is proven in [9] and it is presented in a general version in [13]. The ideas came from an analogous result for lagrangian systems by Mañé [15]. After Jenkinson lecture notes [13] the study of maximizing measures for a fixed dynamical system became known as Ergodic Optimization. Surveys of the subject are presented by Jenkinson [13] and Baraviera, Leplaideur, Lopes [1].

1.1. **Theorem** (Contreras, Lopes, Thieullen [9], see also Jenkinson [13]). Let \( T : X \to X \) be a continuous map of a compact metric space. Let \( E \) be a topological vector space which is densely and continuously embedded in \( C^0(X, \mathbb{R}) \). Write

\[
\mathcal{U}(E) := \{ F \in E \mid \text{there is a unique } F\text{-maximizing measure} \}.
\]

Then \( \mathcal{U}(E) \) is a countable intersection of open and dense sets.

If moreover \( E \) is a Baire space, then \( \mathcal{U}(E) \) is dense in \( E \).

The main conjecture in Ergodic Optimization during the last decade have been wether the maximizing measure for generic Hölder or Lipschitz functions \( F \) is supported on a periodic orbit. For lagrangian systems an analogous statement is known as Mañé’s conjecture.

On the space \( \text{Lip}(X, \mathbb{R}) \) of Lipschitz functions on \( X \) we use the norm

\[
\| f \| := \sup_{x \in X} |f(x)| + \sup_{x \neq y} \frac{|f(x) - f(y)|}{d(x, y)}.
\]

We denote the second term in (1) as \( \text{Lip}(f) \).

Here we prove

**Theorem A.** If \( X \) is a compact metric space and \( T : X \leftrightarrow \) is an expanding map then there is an open and dense set \( \mathcal{O} \subset \text{Lip}(X, \mathbb{R}) \) such that for all \( F \in \mathcal{O} \) there is a single \( F\)-maximizing measure and it is supported on a periodic orbit.

**Corollary B.** For an open and dense set \( \mathcal{O} \) of Lipschitz functions \( F \) on \( X \) the zero temperature limit \( \lim_{\beta \to +\infty} \mu_{\beta F} \) exists and it is supported on a single periodic orbit.

\(^1\) A discontinuous example was given before by Van Enter and Ruszel [19].
On the negative side, for expanding transformations Bousch [3, Proposition 9, p. 306] proves that for generic continuous functions the maximizing measure is not supported on a periodic orbit. Indeed, its support is the total space [3, Rem. 7]. Bousch theorem in the case of hyperbolic sets is presented by Jenkinson in [13, Theorem 4.2].

There have been several approaches to the conjecture from which we will use some of their techniques. Write

$$\mathcal{P}(E) := \{ F \in E \mid \text{the } F\text{-maximizing measure is supported on a periodic orbit} \}.$$  

Contreras, Lopes, Thieullen [9] prove that $\mathcal{P}(E)$ is open for $E = C^\alpha(X, \mathbb{R})$ the space of $\alpha$-Hölder continuous functions and in the $\alpha$-Hölder topology it is open and dense in $E = C^\alpha(X, \mathbb{R})$, the space of functions $F : X \to \mathbb{R}$ such that

$$\forall \eta > 0 \exists \varepsilon > 0 \quad d(x, y) < \varepsilon \implies |F(x) - F(y)| < \eta d(x, y)^\alpha.$$  

The main technique is the introduction of a sub-action $u : X \to \mathbb{R}$ to transform the function $F$ to a cohomologous function $G = F + u \circ T - u$ such that $G \leq a = \int G \, d\mu^G$, where $\mu^G$ is a maximizing measure for $G$ and $F$. The sub-action is defined similarly, and plays the same role, as a sub-solution of the Hamilton-Jacobi equation for Lagrangian systems. In fact analogous constructions to the weak KAM theory can be translated to this setting. In proposition 2.1 we construct a sub-action following the original method by Fathi [10] to construct weak KAM solutions. This method was used in ergodic optimization by Bousch in [2]. In fact many results from Lagrangians systems can be translated to the ergodic optimization setting, see for example [11].

Bousch proves that $\mathcal{P}(E)$ is dense for Walters functions. Yuan and Hunt [21] prove that if a fixed measure is maximizing for an open set of functions $F$ in the Lipschitz topology, then it is supported on a periodic orbit. Their method of perturbation is the basis of the present work. Quas and Siefken [17] work in a one-sided shift. They prove that $\mathcal{P}(E)$ contains an open and dense set if $E$ is the space of super-continuous functions. They present an elegant version of the method of Yuan and Hunt. We need to modify it for Lipschitz functions and pseudo-orbits with finitely many jumps in Proposition 2.4.

Another ingredient of the proof is the following theorem. As a weak version of the conjecture, Morris [16] proves

1.2. Theorem (Morris [16]). Let $X$ be a compact metric space and $T : X \leftrightarrow$ an expanding map. There is a residual set $\mathcal{G} \subset \text{Lip}(X, \mathbb{R})$ such that if $F \in \mathcal{G}$ then there is a unique $F$-maximizing measure and it has zero metric entropy.
The original version of Theorem 1.2 is for Hölder functions in a shift of finite type. In appendix A we describe the modifications from the proof in Morris [16] needed to obtain Theorem 1.2.

2. Preliminars

Let $\epsilon_0 > 0$ and $0 < \lambda < 1$ be such that for every $x \in X$ the branches of the inverse of $T$ are well defined, injective and are $\lambda$-contractions on the ball of radius $\epsilon_0$ centered at $x$.

Given $F \in \text{Lip}(X, \mathbb{R})$, the Lax operator for $F$ is $L_F : \text{Lip}(X, \mathbb{R}) \leftrightarrow$

$$L_F(u)(x) = \max_{y \in T^{-1}(x)} \{ \alpha + F(x) + u(x) \},$$

where

$$\alpha = -\max_{\mu \in \mathcal{M}(T)} \int F \, d\mu.$$

Denote the set of maximizing measures by

$$\mathcal{M}(F) := \left\{ \mu \in \mathcal{M}(T) \mid \int F \, d\mu = -\alpha(F) \right\}.$$  

A calibrated sub-action for $F$ is a fixed point of the Lax operator $L_F$. If $L_F(u) = u$, writing

$$(2) \quad \overline{F} := F + \alpha + u - u \circ T$$

it is easy to see that

(i) $-\alpha(\overline{F}) = \max_{\mu \in \mathcal{M}(T)} \int \overline{F} \, d\mu = 0.$

(ii) $\overline{F} \leq 0.$

(iii) $\mathcal{M}(F) = \mathcal{M}(\overline{F}) = \{ T\text{-invariant measures supported on } [\overline{F} = 0] \}$

2.1. Proposition. There exists a Lipschitz calibrated sub-action.

Proof: We claim that

$$\text{Lip}(L_F(u)) \leq \lambda \left( \text{Lip}(u) + \text{Lip}(F) \right).$$
Indeed, given \( x, y \in X \), let \( \overline{y} \in T^{-1}(y) \) be such that \( \mathcal{L}_F(u)(y) = \alpha + F(\overline{y}) + u(\overline{y}) \). Let \( S \) be the branch of the inverse of \( T \) such that \( S(y) = \overline{y} \). Let \( \overline{x} := S(x) \). Then

\[
\mathcal{L}_F u(x) - \mathcal{L}_F u(y) \leq \alpha + F(\overline{x}) + u(\overline{x}) - \alpha - F(\overline{y}) - u(\overline{y}) \\
\leq (F(\overline{x}) - F(\overline{y})) + (u(\overline{x}) - u(\overline{y})) \\
\leq (\text{Lip}(F) + \text{Lip}(u)) d(\overline{x}, \overline{y}) \\
\leq (\text{Lip}(F) + \text{Lip}(u)) \lambda d(x, y).
\]

The other inequality is similar.

Thus \( \mathcal{L}_F \) leaves invariant the space

\[
\mathbb{E} := \left\{ u \in \text{Lip}(X, \mathbb{R}) \mid \text{Lip}(u) \leq \frac{\lambda \text{Lip}(F)}{1 - \lambda} \right\}.
\]

The quotient space \( \mathbb{E}/\{\text{constants}\} \) is compact and convex and on it \( \mathcal{L}_F \) is continuous. By Schauder Theorem [12, Theorem 18.10, p. 197] \( \mathcal{L}_F \) has a fixed point in \( \mathbb{E} \).

In fact \( \mathcal{L}_F \) is non-expanding in the supremum norm and a simpler fixed point applies [12, Theorem 3.1, p. 28].

If \( u \) is a calibrated sub-action, every point \( z \in X \) has a calibrating pre-orbit, \((z_k)_{k \leq 0}\) such that \( T^i(z_{-i}) = z_0 = z \) and

\[
(3) \quad u(z_{k+1}) = u(z_k) + \alpha + F(z_k), \quad \forall k \leq -1.
\]

Or equivalently, since \( T(z_k) = z_{k+1} \),

\[
\overline{F}(z_k) = 0, \quad \forall k \leq -1.
\]

2.2. Remark. If \( \nu \) is a maximizing measure then by (iii) its support is contained in \( [F = 0] \). If \( z \in \text{supp}(\nu) \) then there is a pre-orbit of \( z \) which is included in \( \text{supp}(\nu) \). Since \( \text{supp}(\nu) \subset [F = 0] \) the pre-orbit must calibrate \( u \). In proposition 2.4 we will obtain a periodic orbit \( \mathcal{O}(y) \) such that the \( \alpha \)-limit of every calibrating pre-orbit is \( \mathcal{O}(y) \). This implies that every maximizing measure has support on \( \mathcal{O}(y) \).

The iteration of equality (3) gives

\[
\forall k \leq -1, \quad u(z_0) = u(z_{-k}) + k\alpha + \sum_{i=-k}^{-1} F(z_i)
\]
for any calibrating pre-orbit.

We say that a sequence \((x_n)_{n \in \mathbb{N}} \subset X\) is a \( \delta \)-pseudo-orbit if \(d(x_{n+1}, T(x_n)) \leq \delta, \forall n \in \mathbb{N}\).

We say that the orbit of \(y \in X\) \( \varepsilon \)-shadows a pseudo-orbit \((x_n)_{n \in \mathbb{N}}\) if \(\forall n \in \mathbb{N}, d(T^n(y), x_n) < \varepsilon\).

2.3. Proposition (Shadowing Lemma).

If \((x_k)_{k \in \mathbb{N}}\) is a \(\delta\)-pseudo-orbit then there is \(y \in X\) whose orbit \(\varepsilon\)-shadows \((x_k)\) with \(\varepsilon = \frac{\delta}{1-\lambda}\). If \((x_k)\) is a periodic pseudo-orbit then \(y\) is a periodic orbit with the same period.

Proof: Write \(B(x, r) := \{z \in X \mid d(z, x) \leq r\}\) and \(a := \frac{\lambda \delta}{1-\lambda}\). Let \(S_k\) be the branch of the inverse of \(T\) such that \(S_k(T(x_k)) = x_k\). We have that
\[
S_k(B(x_{k+1}, a)) \subseteq S_k(B(T(x_k), a + \delta)) \subseteq B(x_k, \lambda(a + \delta)) = B(x_k, a).
\]
Let \(y \in X\) be given by
\[
y = \bigcap_{k=0}^{\infty} S_0 \circ \cdots \circ S_k(B(x_{k+1}, a)).
\]
The point \(y\) exists and is unique because it is the intersection of a nested family of non-empty compact sets with diameter smaller than \(2a\lambda^k\). We have that \(T^k(y) \in B(x_k, a)\). Thus \(y\) \(a\)-shadows \((x_k)\). Now suppose \(x_k\) is \(p\)-periodic. Then also \(T^p(y)\) \(a\)-shadows \((x_k)\).

The uniqueness of \(y\) implies that \(T^p(y) = y\).

\[
\square
\]

We show now a condition which permits to obtain a perturbation with maximizing measure supported on a periodic orbit. The argument appeared first in Yuan and Hunt [21]. The proof below is a modification that we shall need of the arguments by Quas and Sieffken [17] which we adapt to pseudo-orbits.

Let \(y \in \text{Per}(T) = \cup_{p \in \mathbb{N}^+} \text{Fix}(T^p)\) be a periodic point for \(T\). Let \(P_y\) be the set of Lipschitz functions \(F \in \text{Lip}(X, \mathbb{R})\) such that there is a unique \(F\)-maximizing measure and it is supported on the positive orbit of \(y\). Let \(\overset{\circ}{P}_y\) be the interior of \(P_y\) in \(\text{Lip}(X, \mathbb{R})\).

2.4. Proposition. Let \(F, u \in \text{Lip}(X, \mathbb{R})\) with \(\mathcal{L}_F(u) = u\) and let \(\Phi\) be defined by (2).

Let \(M \in \mathbb{N}^+\). Suppose that for any \(\delta > 0\) there is a \(p(\delta)\)-periodic \(\delta\)-pseudo orbit \((x^\delta_k)_{k \in \mathbb{N}}\) in \([\Phi = 0]\) with at most \(M\) jumps such that if \(\gamma_\delta := \min_{0 \leq i < p(\delta)} d(x^\delta_i, x^\delta_j)\) then \(\lim_{\delta \to 0} \frac{\gamma_\delta}{\delta} = \infty\).

Then \(F\) is in the closure of \(\cup_{y \text{periodic}} \overset{\circ}{P}_y\).
Proof: Observe that fixing $u$, for any $H \in \text{Lip}(X, \mathbb{R})$ the functions $H$ and $H + \alpha(F) + u - u \circ T$ have the same maximizing measures. Therefore it is enough to prove that the function $F$ is in the closure of $\cup_{y \text{periodic}} \overset{o}{F}_y$.

Let $\varepsilon > 0$. We will show a perturbation of $F$ with Lipschitz norm smaller than $\varepsilon$ such that it has a unique maximizing measure supported on a periodic orbit. Moreover, we will exhibit a neighborhood of the perturbed function in which the same periodic orbit is the unique maximizing measure for all functions in the neighborhood. The neighborhood will depend on the periodic orbit.

Let
\[ K := \max \left\{ \frac{M \text{Lip}(F)}{(1-\lambda)^2}, \frac{\text{Lip}(F) + 2}{1-\lambda} \right\}, \]
\[ \gamma_3 := \frac{1}{\text{Lip}(F)} \left( \gamma - \frac{2\delta}{1-\lambda} - \delta \right). \]

Assume that $\frac{\gamma}{\delta}$ is so large that
\[ 3K\delta - \varepsilon\gamma_3 =: -2a < 0. \]

Let $y$ be the $p$-periodic point which $(\frac{\delta}{1-\lambda})$-shadows $(x_k)$. Write $y_k := T^k(y)$ and
\[ \mathcal{O}(y) = \{T^i(y) \mid i = 0, \ldots, p - 1\} = \{y_0, \ldots, y_{p-1}\}. \]

For a function $G : X \to \mathbb{R}$ write
\[ \langle G \rangle(y) = \frac{1}{p} \sum_{i=0}^{p-1} G(T^i(y)). \]

Let $n_i, i = 1, \ldots, \ell, \ell \leq M$, be the jumps of $(x_k)$; i.e. $d(T(x_k), x_{k+1}) = 0$ if $k \notin \{n_1, \ldots, n_\ell\}$. We have that
\[ \left| \sum_{k=n_i-1}^{n_i} F(y_k) - \sum_{k=n_i-1}^{n_i} F(x_k) \right| \leq \sum_{k=n_i-1}^{n_i} \text{Lip}(F) d(y_k, x_k) \leq \sum_{k=0}^{n_i-n_{i-1}} \lambda^k \frac{\delta}{1-\lambda} \text{Lip}(F) \]
\[ \leq \frac{\text{Lip}(F)}{(1-\lambda)^2} \delta. \]

Thus
\[ \left| \sum_{k=0}^{p-1} F(y_k) - \sum_{k=0}^{p-1} F(x_k) \right| \leq \frac{M \text{Lip}(F)}{(1-\lambda)^2} \delta. \]
By hypothesis $\forall k, \mathcal{F}(x_k) = 0$, thus $\sum_{k=0}^{p-1} \mathcal{F}(x_k) = 0$. Therefore

$$\sum_{k=0}^{p-1} \mathcal{F}(y_k) \geq -\frac{M \text{Lip}(\mathcal{F})}{(1-\lambda)^2} \delta \geq -K\delta,$$

(5)

$$\langle \mathcal{F} \rangle(y) \geq -\frac{K\delta}{p}.$$

Observe that if $0 \leq i < j < p$

$$d(y_i, y_j) \geq -d(y_i, x_i) + d(x_i, x_j) - d(x_j, y_j) > \frac{2\delta}{1-\lambda} =: \gamma_2.$$

Claim: Assume that $d(z, y_k) \leq \delta < e_0$. Take $w_1 \in T^{-1}\{z\}$ such that $d(w_1, y_{k-1}) < \lambda\delta$. If $w_2 \in T^{-1}\{z\} \setminus \{w_1\}$ then

$$d(w_2, \mathcal{O}(y)) \geq \gamma_3 := \frac{\gamma_2 - \delta}{\text{Lip}(T)} \gg \delta.$$

Proof: Let $y_j \in \mathcal{O}(y)$ be such that $d(w_2, \mathcal{O}(y)) = d(w_2, y_j)$. Observe that $j \neq k-1$ because $T$ is injective in the ball $d(\cdot, y_{k-1}) \leq \lambda\delta$. Then

$$\gamma_2 < d(y_k, y_{j+1}) \leq d(y_k, z) + d(z, y_{j+1}) \leq \delta + \text{Lip}(T)d(w_2, y_j).$$

This proves the claim.

Now we make two perturbations to $\mathcal{F}$. The first perturbation is the addition of $-\varepsilon g(x)$, where

$$g(x) := d(x, \mathcal{O}(y)),$$

and $\varepsilon$ depends on $\delta$ and $\gamma$. This is a perturbation with $\text{Lip}(\varepsilon g) = \varepsilon$. The second is a perturbation by any function with

$$\|h\|_0 < \frac{K\delta}{2p}, \quad \text{Lip}(h) \leq 1.$$

(6)

This perturbation depends on $\mathcal{O}(y)$, and in particular on its period $p$. We shall prove that the function $G_1 := \mathcal{F} - \varepsilon g + h$ has a unique maximizing measure supported on the periodic orbit $\mathcal{O}(y)$. Since the set of such functions $G_1$ contains an open ball centered at $\mathcal{F} - \varepsilon g$, this proves the proposition.

Let

$$G = \mathcal{F} - \varepsilon g + h + \beta = G_1 + \beta,$$

(7)
where

\[ \beta = - \sup_{\mu \in \mathcal{M}(T)} \int (\mathcal{F} - \varepsilon g + h) \, d\mu. \]

It is enough to prove the claim for \( G \) because \( G \) and \( G_1 \) have the same maximizing measures.

Using (5), we have that

\[ \beta \leq - \langle \mathcal{F} - \varepsilon g + h \rangle (y) = - \langle \mathcal{F} + h \rangle (y) \]
\[ \leq - \langle \mathcal{F} \rangle (y) + \| h \|_0 \]
\[ \leq \frac{K \delta}{p} + \| h \|_0 \]

(8)

Let \( v \) be a calibrated sub-action for \( G \), \( L_G(v) = v \). Given any \( z \in X \) let \( (z_k)_{k \leq 0} \) be a pre-orbit of \( z \) which calibrates \( v \). Let \( 0 > t_1 > t_2 > \cdots \) be the times on which \( d(z_k, \mathcal{O}(y)) > \delta \). Then for each \( n \in \mathbb{N}^+ \) there is \( s_n \in \mathbb{Z} \) such that the orbit segment \( (z_k)_{k=t_n+1}^{t_n+1} \) \( \delta \)-shadows \( (y-i+s_n)_{i=t_n-t_{n+1}-1} \), thus

\[ d(z_i+t_{n+1}, y-i+s_{n+1}) \leq \lambda^{i-1} \delta, \quad \forall n \in \mathbb{N}, \quad \forall i = 1, \ldots, t_n - t_{n+1} - 1. \]

By the Claim, we have that

(9)

\[ d(z_{t_n}, \mathcal{O}(y)) \geq \gamma_3. \]

Since both terms in \( \mathcal{F} - \varepsilon g \) are non-positive, from (7) and (8) we obtain

(10)

\[ G \leq h + \beta \leq \frac{K \delta}{p} + 2 \| h \|_0. \]

On a shadowing segment we have

\[
\left| \sum_{k=t_{n+1}+1}^{t_n-1} G(z_k) - \sum_{s_n-t_n+t_{n+1}-1}^{s_n-1} G(y_k) \right| \leq \operatorname{Lip}(G) \sum_{i=0}^{\infty} \lambda^i \delta \leq \operatorname{Lip}(G) \frac{\delta}{1-\lambda} \leq K \delta.
\]

Write

\[ t_n - t_{n+1} - 1 = mp + r \]

with \( 0 \leq r < p \) and separate the shadowing segment in \( m \) loops around the orbit \( \mathcal{O}(y) \) and a residue with at most \( p - 1 \) iterates. Using (10) for \( (p - 1) \) times, we have that

\[
\sum_{k=t_{n+1}+1}^{t_n-1} G(z_k) \leq mp \langle G \rangle (y) + (p - 1) \frac{K \delta}{p} + 2(p - 1) \| h \|_0 + \operatorname{Lip}(G) \frac{\delta}{1-\lambda}.
\]
By the definition of $\beta$ we have that $(G)(y) \leq 0$. Therefore

$$G(z_k) \leq (p - 1) \frac{K\delta}{p} + 2(p - 1) \|h\|_0 + K\delta.$$  \hspace{1cm} (11)

On the points $z_{t_n}$ far from $O(y)$, using (7), (9) and (10), we have that

$$G(z_{t_n}) \leq 0 - \varepsilon \gamma_3 + \|h + \beta\|_0 \leq -\varepsilon \gamma_3 + \frac{K\delta}{p} + 2\|h\|_0.$$  \hspace{1cm} (12)

Thus, adding (11) and (12), and using (6) and (4)

$$\sum_{t_{n+1}+1}^{t_n-1} G(z_k) \leq 2p \|h\|_0 + 2K\delta - \varepsilon \gamma_3 < -a < 0.$$  \hspace{1cm} (13)

Since $v$ is finite and $(z_k)$ is a calibrating pre-orbit for $v$, we have that for every $k \leq 0$,

$$v(z) = v(z_k) + \sum_{i=k+1}^{-1} G(z_i)$$

Thus

$$\sum_{-\infty}^{-1} G(z_k) \geq -2 \|v\|_0 > -\infty.$$ From (13) we obtain that the sequence $t_n$ is finite. Thus every calibrating pre-orbit has $\alpha$-limit $O(y)$. By remark 2.2, this implies that every maximizing measure for $G$ has support on $O(y)$.

$\square$

3. Proof of Theorem A

Proof of theorem A:

We prove that $\cup_{y \in \text{Per}(T)} \mathcal{O}_y^\circ$ is open and dense. It is clearly open.

Suppose that there is a non-empty open set

$$\mathcal{U} \subset \text{Lip}(X, \mathbb{R})$$

which is disjoint from $\cup_{y \in \text{Per}(T)} \mathcal{O}_y^\circ$. Let $F \in \mathcal{U}$. Let $\mu$ be an ergodic maximizing measure for $F$. By Theorem 1.2 we can assume that the entropy of $\mu$ is

$$h_\mu(T) = 0.$$  \hspace{1cm} (15)
By (iii) for any calibrating subaction $u$, $\text{supp}(\mu) \subset \{F = 0\}$. Let $q \in X$ be a generic point for $\mu$, i.e. for any continuous function $f : X \to \mathbb{R}$,

$$\int f \, d\mu = \langle f \rangle(q) = \lim_{N \to \infty} \frac{1}{N} \sum_{i=0}^{N-1} f(T^i(q)).$$

By Proposition 2.4 with $M = 2$ there is $Q > 0$ and $\delta_0 > 0$ such that if $(x_k)_{k \geq 0} \subset \mathcal{O}(q)$ is a $p$-periodic $\delta$-pseudo-orbit with at most 2 jumps made with elements of the positive orbit of $q$ and $0 < \delta < \delta_0$ then $\gamma = \min_{1 \leq i < j < p} d(x_i, x_j) < Q\delta$.

Let $N_0$ be such that

$$2 Q^{-N_0} < \delta_0. \quad (16)$$

Fix a point $w \in \text{supp}(\mu)$ for which Brin-Katok Theorem holds [6], i.e.

$$h_\mu(T) = -\lim_{L \to +\infty} \frac{1}{L} \log \mu(V(w, L, \varepsilon)), \quad (17)$$

where $V(w, L, \varepsilon)$ is the dynamic ball:

$$V(w, L, \varepsilon) := \{ x \in X \mid d(T^k x, T^k w) < \varepsilon, \forall k = 0, \ldots, L \}. \quad (18)$$

Given $N > N_0$ let $0 \leq t_1^N < t_2^N < \cdots$ be all the $Q^{-N}$ returns to $w$, i.e.

$$\{t_1^N, t_2^N, \ldots\} = \{ n \in \mathbb{N} \mid d(T^n q, w) \leq Q^{-N} \}.$$

We need the following

3.1. **Proposition.** For any $\ell \geq 0$, $\quad t_{\ell+1}^N - t_\ell^N \geq \sqrt{2^{N-N_0-1}}$.

Using Proposition 3.1 we continue the proof of Theorem A.

Write

$$B(w, r) := \{ x \in X \mid d(x, w) \leq r \}.$$  

Given $N \gg N_0$, let $f_N : X \to \mathbb{R}$ be a continuous function such that $0 \leq f \leq 1$, $f|_{B(w, Q^{-N-1})} \equiv 1$ and supp$f \subseteq B(w, Q^{-N})$. Using that $q$ is a generic point for $\mu$ and
Proposition 3.1, we have that
\[
\mu(B(w, Q^{N-1})) \leq \int f_N \, d\mu = \lim_{L \to +\infty} \frac{1}{L} \sum_{i=0}^{L-1} f_N(T^i w)
\]
\[
\leq \lim_{L \to +\infty} \frac{1}{L} \# \{ 0 \leq i < L \mid d(q_i, w) \leq Q^{-N} \}
\]
\[
\leq \lim_{L \to +\infty} \frac{1}{L} \# \{ \ell \mid t_{\ell}^N \leq L \}
\]
\[
\leq \sqrt{2}^{-N+N_0+1}.
\]
(19)

Recall that the dynamic ball about \( w \) is
\[
V(w, L, \varepsilon) := \{ x \in X \mid d(T^k x, T^k w) < \varepsilon, \forall k = 0, \ldots, L \}.
\]
We have that
\[
V(w, L, \varepsilon) = S_1 \circ \cdots \circ S_L(B(T^L w, \varepsilon)),
\]
where \( S_k \) is the branch of the inverse of \( T \) such that \( S_k(T^k w) = T^{k-1} w \). Therefore
\[
V(w, L, \varepsilon) \subseteq B(w, \lambda^L \varepsilon).
\]
Let \( N \) be such that
\[
Q^{-N-2} \leq \lambda^L \varepsilon \leq Q^{-N-1}.
\]
Then
\[
-N \leq L \frac{\log \lambda}{\log Q} + \frac{\log \varepsilon}{\log Q} + 2.
\]
Using (19), we have that
\[
\mu(V(w, L, \varepsilon)) \leq \mu(B(w, \lambda^L \varepsilon)) \leq \mu(B(w, Q^{-N-1})) \leq \sqrt{2}^{-N+N_0+1}.
\]
\[
\frac{1}{L} \log \mu(V(w, L, \varepsilon)) \leq \frac{1}{L} \left( \log \sqrt{2} \right) \left( -N + N_0 + 1 \right)
\]
\[
\leq \frac{\log \lambda}{\log Q} \log \sqrt{2} + \frac{1}{L} \left( \log \sqrt{2} \right) \left( 2 + \frac{\log \varepsilon}{\log Q} + N_0 + 1 \right).
\]
By Brin-Katok Theorem [6] we have that
\[
h_{\mu}(T) = -\lim_{L \to +\infty} \frac{1}{L} \log \mu(V(w, L, \varepsilon)) \geq \frac{\log \lambda^{-1}}{\log Q} \log \sqrt{2} > 0.
\]
This contradicts the choice of \( F \) in (15). Therefore such non-empty open set \( \mathcal{U} \) in (14) does not exist. This implies that the (open) set \( \cup_{y \in \text{Per}(T)} \hat{P}_y \) is dense. \( \square \)
Now we prove

3.1. Proposition. For any $\ell \geq 0$, $t_{\ell+1}^N - t_\ell^N \geq \sqrt{2^{N-N_0}-1}$.

Proof: For $N \in \mathbb{N}$, let
$$A_N := \{(x,y) \in X \times X \mid d(x,y) \leq Q^{-N}\}.$$

From (16) if $N > N_0$ and $(x_k)_{k=0}^{p-1}$ is a $p$-periodic $2Q^{-N}$ pseudo-orbit in $O(q)$ with at most 2 jumps, then there is a $Q^{-N+1}$-return $(x_i, x_j) \in A_{N-1}$ with $0 \leq i < j \leq p - 1$.

Write $q_i := T^i(q)$. The sequence $(q_k)_{k=t_\ell^N}^{t_{\ell+1}^N-1}$ is a periodic $Q^{-N}$ pseudo-orbit in $O(q)$ with 1 jump. Therefore there is a $Q^{-N+1}$-return $d(q_i, q_j) \leq Q^{-N+1}$ with $t_\ell^N \leq i < j \leq t_{\ell+1}^N - 1$.

This gives rise to two $Q^{-N+1}$ periodic pseudo-orbits in $O(q)$ with at most 2 jumps. Namely, $(q_i, \ldots, q_{j-1})$ and $(q_j, \ldots, q_{t_{\ell+1}^N-1}, q_{t_\ell^N}, \ldots, q_{i-1})$. Each of them give rise to a $Q^{-N+2}$ return.

![Figure 1. Example of a cascade of returns implied by the inductive process.](image)

It is simpler to show the inductive process in a picture. Draw a circle $S$ with the elements of the pseudo-orbit $(q_k)_{k=t_\ell^N}^{t_{\ell+1}^N-1}$. Inside the disk $\mathbb{D}$, draw a line from $q_i$ to $q_j$. It may be that $q_i = q_{t_\ell^N}$ but in that case $q_j \neq q_{t_{\ell+1}^N}$. The line $\ell_1 = \overline{q_i q_j}$ separates the disk in two components. Each component is a $Q^{-N+1}$ pseudo-orbit with at most two jumps (one jump of size $\leq Q^{-N+1}$ and possibly another with size $\leq Q^{-N} < Q^{-N+1}$). Thus, each component has at least one $Q^{-N+2}$ return... The interior of the lines in this construction do not intersect.

We will also draw a tree with the returns, in order to see that their number grows exponentially. An example appears in figure 2. The nodes of the tree are the returns...
implied by Proposition 2.4. The height\footnote{A node in level $N - 2$ corresponds to a return $(q_i, q_j) \in \mathbb{A}_{N-2}$ with $d(q_i, q_j) \leq Q^{-N+2}$. The distance could actually be smaller. The height in the tree is just the distance implied by the previous steps in the construction of the tree. It if was smaller it would imply a larger subtree from that point, this helps the argument.} of the node corresponds to the size of the return. The numbers near a node are the quantity of returns in upper levels of the tree which are adjacent to the return of the node, either at its left or at its right. These numbers are also equal to $-1 +$ the quantity of jumps of the two new periodic pseudo-orbits determined by the node.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{tree_example}
\caption{An example of a distribution of returns implied by Proposition 2.4 and the tree representing it. The shadow is explained after inequality (20).}
\end{figure}

We show how the tree is constructed in the example of figure 2. We begin with a return in $\mathbb{A}_N$. This gives a periodic $Q^{-N}$ pseudo-orbit with no other jump. It implies the existence of a return in $\mathbb{A}_{N-1}$. In the tree we draw a vertical line from level $N$ to level $N - 1$. At this stage, the line in the circle corresponding to the $\mathbb{A}_{N-1}$ return divides the disk in two components. One side has 1 return in $\mathbb{A}_N$ that appears in a previous level in the tree and the other side has 0 returns appearing above in the tree. We write the numbers 0 and 1 at the sides of the node of the tree corresponding to the $\mathbb{A}_{N-1}$ return.

The $\mathbb{A}_{N-1}$ return divides the circle in two components. The component at the left is a periodic $Q^{N-1}$ pseudo-orbit with only one $Q^{N-1}$ jump, corresponding to the number 0 in the tree. The component at the right is a $Q^{N-1}$ pseudo-orbit with a $Q^{N-1}$ jump and also a $Q^N$ jump, and corresponds to the number 1 in the tree in the node at level $N - 1$. Proposition 2.4 implies the existence of other returns in $\mathbb{A}_{N-2}$ for both pseudo-orbits. In the right hand side of figure 2 we draw the case in which the pseudo-orbit segment between the $\mathbb{A}_{N-2}$ return contains a $Q^{-N}$ jump. Cutting the $Q^{N-1}$ pseudo-orbit of the right hand side of the circle at the $\mathbb{A}_{N-2}$ return we obtain two $Q^{N-2}$ periodic pseudo-orbits. The one
at the right has a $Q^N$ jump which appears previously in the tree and the one at the left has a $Q^{N-1}$ jump appearing previously in the tree. We write the numbers 1 and 1 in the corresponding node of the tree.

![Figure 3](image)

**Figure 3.** If the return implied by Proposition 2.4 contains one of the endpoints of the mother periodic pseudo-orbit we observe that it divides the mother pseudo-orbit in two child pseudo-orbits. We draw lines connecting the ends of these pseudo-orbits and shadow the internal part of the disk $D$ which does not contain an interval in the circle $S$.

We want to assure that each node of the tree corresponds to a return which has at least one new point of the pseudo-orbit $(q_{t_{N}}^{1}, \ldots, q_{t_{N}+1}^{1})$ which did not appear in the returns corresponding to the other nodes of the tree. So that we have

$$t_{N}^{t_{N}+1} - t_{N}^{t} \geq \#\{\text{nodes}\}.$$  

Given a $Q^{-B}$ periodic pseudo-orbit $(q_{a}, \ldots, q_{b-1})$ with at most $M = 2$ jumps we get a return $(i, j)$ with $d(q_{i}, q_{j}) \leq Q^{-B+1}$, $a \leq i < j \leq b$. It may happen that $i = a$ or $j = b - 1$ but not both, because it would be the same return we started with. Say $i = a$. The next return in the construction of the tree could be $(j, b)$ and in that case the new node in the tree does not correspond to a new element in the pseudo-orbit, the points $q_{a}$, $q_{i}$, $q_{b}$ were already counted. To avoid this situation we observe that $(q_{j}, \ldots, q_{b-1})$ is indeed a $2Q^{-B}$ periodic pseudo-orbit because $d(q_{j}, q_{b}) \leq d(q_{j}, q_{a}) + d(q_{a}, q_{b}) = d(q_{j}, q_{i}) + d(q_{a}, q_{b})$. In the disk we draw two new lines $q_{a}q_{j}$ and $q_{j}q_{b}$ and shadow the region bounded by these two lines and $q_{a}q_{b}$. We treat the region as a new line. This is, the two new components in the $(\text{disk } D) \setminus \{\text{shadow}\}$ are treated as the two sides of a new line in $D$ corresponding to a node in the tree. The numbers in the node are -1 + the quantity of jumps of each of the pseudo-orbits determined by the components.

We describe in figures 4 – 7 all the possibilities for a vertical step of size one of the tree’s construction. The “bitten” parts are returns which appeared previously in the tree’s construction. In the case of a node at level $B$ with numbers $(0, 2)$, for $M = 2$ Proposition 2.4 does not give a new return for the side which already has 2 returns. In
this case Proposition 2.4 only implies that there is one return in $A_{B-1}$ in the side which had 0 previous returns. Then for a node at level $B$ with numbers $(0, 2)$ we draw only one vertical line to level $B - 1$.

Figure 4. These are all the cases for a node in the tree with numbers $(0, 0)$. Since the beginning numbers are $(0, 1)$, the numbers $(0, 0)$ appear only with a shadow i.e. returns to the beginning (and end) of the pseudo-orbit.

The tree is constructed by joining the pieces shown in these figures. Except for the nodes with numbers $(0, 2)$ all the other nodes have two child nodes. All the nodes have at least one child. The nodes with numbers $(0, 2)$ in figure 7 have one child with numbers different from $(0, 2)$. This implies that they have at least two grandchildren nodes. This is graphically shown in figure 8. Therefore the quantity of nodes at least duplicates in every sequence of two vertical steps. The tree continues growing while the height number is larger than $N_0$. Thus it has at least $N - N_0$ vertical steps and then at least $(N - N_0 - 1)/2$ sequences of two vertical steps (and hence duplication of nodes). We obtain

$$t_{\ell+1}^N - t_\ell^N \geq \#\{\text{nodes}\} \geq 2^{\frac{N-N_0-1}{2}}.$$

Figure 6. The case of a node with numbers \((1, 1)\) is symmetric with respect to a reflection with axis \(BB\) = the line joining the returning points. Here we show the three possibilities at the right hand side of the axis \(BB\). There are 9 possibilities for a node with numbers \((1, 1)\) given by all the combinations of the three cases shown in the figure at the right hand side and the three symmetric cases at the left hand side. All the possibilities have two child nodes.

Figure 7. In a node with numbers \((0, 2)\) one side is a pseudo-orbit with \(M + 1 = 3\) nodes. Since we have chosen \(M = 2\), Proposition 2.4 does not apply and we leave that side without a child node. The other side has a child node with numbers \((0, 0)\) or \((0, 1)\). Both cases have been analyzed before: the child node has in turn two children nodes.

In this appendix we prove Theorem 1.2.

We need two lemmas.

A.1. Lemma. Let \(a_1, \ldots, a_n\) be non-negative real numbers, and let \(A = \sum_{i=1}^{n} a_i \geq 0\). Then
\[
\sum_{i=1}^{n} -a_i \log a_i \leq 1 + A \log n,
\]
where we use the convention \(0 \log 0 = 0\).

Proof: Applying Jensen’s inequality to the concave function \(x \mapsto -x \log x\) yields
\[
\frac{1}{n} \sum_{i=1}^{n} -a_i \log a_i \leq -\left(\frac{1}{n} \sum_{i=1}^{n} a_i\right) \log \left(\frac{1}{n} \sum_{i=1}^{n} a_i\right) = -\frac{A}{n} \log A + \frac{A}{n} \log n
\]
from which the result follows. \(\square\)

A.2. Lemma. Let \(f \in \text{Lip}(X, \mathbb{R})\) and suppose that \(\mathcal{M}_{\text{max}}(f) = \{\mu\}\) for some \(\mu \in \mathcal{M}(T)\). Then there is \(C > 0\) such that for every \(\nu \in \mathcal{M}(T)\),
\[
-\alpha(f) - C \int d(x, K) \, d\nu \leq \int f \, d\nu,
\]
where \(K = \text{supp} \, \mu\).

Proof: By Proposition 2.1 there exists \(g \in \text{Lip}(X, \mathbb{R})\) such that \(f + g - g \circ T \leq -\alpha(f)\). Define \(\tilde{f} = f + g - g \circ T\). Since \(\tilde{f}\) is continuous, \(\int \tilde{f} \, d\mu = \int f \, d\mu = -\alpha(f)\) and \(\tilde{f} \leq -\alpha(f)\), it follows that \(\tilde{f}(x) = -\alpha(f)\) for every \(x \in K = \text{supp} \, \mu\). Let \(C = \text{Lip} (\tilde{f})\). Given \(x \in X\), let \(z \in K\) be such that \(d(x, z) = d(x, K)\); we then have
\[
\tilde{f}(x) \geq \tilde{f}(z) - C \, d(x, z) = -\alpha(f) - C \, d(x, K)
\]
from which the result follows. \(\square\)

1.2. Theorem (Morris [16]). Let \(X\) be a compact metric space and \(T : X \leftrightarrow\) an expanding map. There is a residual set \(\mathcal{G} \subset \text{Lip}(X, \mathbb{R})\) such that if \(F \in \mathcal{G}\) then there is a unique \(F\)-maximizing measure and it has zero metric entropy.
**Proof of Theorem 1.2:**

For $p \geq 1$ let $\mathcal{M}^p(T)$ be the set of invariant probabilities supported on periodic of period smaller or equal to $p$. In this appendix we will identify a periodic orbit $\{z, Tz, \ldots, T^{p-1}z\}$ with the corresponding invariant measure $\mu = \frac{1}{p} \sum_{i=0}^{p-1} \delta_{T^i z}$.

Let

$$\epsilon_0 > 0, \quad 0 < \lambda < 1$$

be such that for every $x \in X$ the branches of the inverses of $T$ at $x$ are well defined, injective, and are $\lambda$-contractions on the ball $B(x, \epsilon)$ of radius $\epsilon$ centered at $x$.

Let

$$\mathcal{E}_\gamma := \{ f \in \text{Lip}(X, \mathbb{R}) \mid h(\mu) < 2 \gamma h_{\text{top}}(T) \quad \forall \mu \in \mathcal{M}_{\text{max}}(f) \}.$$ 

It is enough to prove that $\mathcal{E}_\gamma$ is open and dense for every $\gamma > 0$.

**Step 1.** $\mathcal{E}_\gamma$ is open.

Suppose that $f \in \text{Lip}(X, \mathbb{R})$, $f_n \in \text{Lip}(X, \mathbb{R}) \setminus \mathcal{E}_\gamma$ and $\lim_n f_n = f$ in $\text{Lip}(X, \mathbb{R})$. Then there are $\nu_n \in \mathcal{M}_{\text{max}}(f_n)$ with $h(\nu_n) \geq 2 \gamma h_{\text{top}}(T)$. Taking a subsequence if necessary, we may assume that $\nu_n \to \nu \in \mathcal{M}(T)$. We have

$$\int f \, d\mu - \|f - f_n\|_\infty \leq \int f_n \, d\mu \leq \int f_n \, d\nu_n \leq \int f \, d\nu_n + \|f - f_n\|_\infty.$$ 

Thus $\int f \, d\mu \leq \int f \, d\nu$ and $\nu \in \mathcal{M}_{\text{max}}(T)$. Since the map $m \mapsto h(m)$ is upper semicontinuous (see e.g. [20]) we have that $h(\nu) \geq 2 \gamma h_{\text{top}}(T)$. Therefore $f \in \text{Lip}(X, \mathbb{R}) \setminus \mathcal{E}_\gamma$. We conclude that $\text{Lip}(X, \mathbb{R}) \setminus \mathcal{E}_\gamma$ is closed and then $\mathcal{E}_\gamma$ is open.

**Step 2.** We have to prove that $\mathcal{E}_\gamma$ intersects every non-empty open set. Let $U \subset \text{Lip}(X, \mathbb{R})$ be open and non-empty. By Theorem 1.1 there is $f \in U$ such that $\mathcal{M}_{\text{max}}(f)$ has only one element. If this element is a periodic orbit then $f \in \mathcal{E}_\gamma \cap U$ and we are done. Otherwise by Lemma A.2 there is a real number $C > 0$ and a compact invariant set $K$ such that for every $\mu \in \mathcal{M}(T)$

$$-\alpha(f) - C \int d(x, K) \, d\mu \leq \int f \, d\mu$$

and such that $K$ does not contain a periodic orbit.

Let $\beta > 0$ be small enough that $f + g \in U$ whenever $\|g\|_\beta \leq 2\beta$. We will construct a sequence of approximating functions such $f_n \in U \cap \mathcal{E}_\gamma$ for $n$ large enough. In the next two steps we choose a sequence of periodic orbits which will be used in the construction.
Step 3.

Claim: Given any $0 < \theta < 1$, there is a sequence of integers $(m_n)_n$ and a sequence of periodic orbits $\mu_n \in \mathcal{M}^n(T)$ such that

$$\int d(x, K) \, d\mu_n = o(\theta^{m_n}) \quad \text{and} \quad \lim_{n \to \infty} \frac{\log n}{m_n} = 0.$$ 

Proof of the Claim. By a theorem of Bressaud and Quas [5, Corollary 3 and Theorem 4] for every $k > 0$

(23) \[ \lim_{n \to +\infty} n^k \left( \inf_{\mu \in \mathcal{M}^n(T)} \int d(x, K) \, d\mu \right) = 0. \]

Indeed recall that using a Markov partition (cf. Ruelle [18, §7.29]) the map $T$ is Hölder continuously semi-conjugate to a shift of finite type. This is enough to obtain estimate (23) (see the proof of Corollary 3 in Bressaud and Quas [5]).

From (23) there exists a sequence of periodic orbits $\mu_n \in \mathcal{M}^n(T)$ such that

$$\lim_{n \to +\infty} n^k \int d(x, K) \, d\mu_n = 0.$$ 

Define

$$r_n := \log_\theta \left( \int d(x, K) \, d\mu_n \right).$$

Since

$$\theta^{r_n} \leq n^k \theta^{r_n} \leq 1 \quad \iff \quad 0 \geq \frac{\log n}{r_n} \geq -\frac{1}{k},$$

we have that $r_n^{-1} \log n \to 0$. Define $m_n := \lfloor \frac{1}{2} r_n \rfloor$, then $m_n^{-1} \log n \to 0$ and

$$\int d(x, K) \, d\mu_n = \theta^{r_n} \leq \theta^{m_n + \frac{1}{2} r_n} = o(\theta^{m_n})$$

as required.

Step 4. For each $n \geq 1$ define $L_n := \text{supp} \mu_n$. Using (21), fix

(24) \[ 0 < \theta < \min\{\varepsilon_0, \lambda\}. \]

Claim: There is $N_\gamma > 0$ such that when $n \geq N_\gamma$

$$\nu(\{ x \in X \mid d(x, L_n) \geq \theta^{m_n} \}) > \gamma$$

for every invariant measure $\nu \in \mathcal{M}(T)$ such that $h(\nu) \geq 2_\gamma h_{\text{top}}(T)$. 
Proof of the Claim.

Recall that a Markov partition for $T$ is a finite collection of sets $S_i$ which cover $X$ such that

(a) $S_i = \overline{\text{int} S_i}$.
(b) If $i \neq j$ then $\text{int} S_i \cap \text{int} S_j = \emptyset$.
(c) $f(S_i)$ is a union of sets $S_j$.

Ruelle [18, §7.29] proves that for expanding maps there are Markov partitions of arbitrarily small diameter. Let $P$ be a Markov partition with $\text{diam} P < \varepsilon_0$. The elements of the partition

$$P^{(n)} := \bigvee_{i=0}^{n-1} T^{-i} P = \left\{ \bigcap_{i=0}^{n-1} A_i \mid A_i \in T^{-i} P \right\}$$

have diameter smaller than $\lambda^{n-1} \varepsilon_0$ and contain an open set. Then the partition $P$ is generating because the $\sigma$-algebra

$$P^\infty = \sigma\left( \bigcup_n P^{(n)} \right) = \text{Borel}(X).$$

contains all the open sets. Therefore for every invariant measure $\nu \in \mathcal{M}(T)$,

$$h(\nu) = \inf_k \frac{1}{k} \sum_{A \in P^{(k)}} -\nu(A) \log \nu(A).$$

From the definition of topological entropy using covers (cf. Walters [20, §7.1]) we have that

$$\lim_{k \geq 1} \frac{1}{k} \log \# P^{(k)} \leq h_{\text{top}}(T).$$

Choose $N_\gamma$ large enough that for all $n \geq N_\gamma$

$$2 + \log \frac{\# P}{m_n} + \log \frac{n}{m_n} + \frac{\gamma}{m_n} \log \# P^{(m_n)} < 2\gamma h_{\text{top}}(T). \quad (25)$$

Let $\nu \in \mathcal{M}(T)$ and suppose that

$$\nu(\{ x \in X \mid d(x, L_n) \geq \theta^{m_n} \}) \leq \gamma \quad (26)$$

for some $n \geq N_\gamma$. We will show that necessarily $h(\nu) < 2\gamma h_{\text{top}}(\nu)$.

Let

$$W_n := \{ A \in P^{(m_n)} \mid d(x, L_n) < \theta^{m_n} \quad \text{for some } x \in A \}.$$
From (26),
\[
\tilde{\gamma}_n := \sum_{A \in \mathcal{P}^{(m_n)} \setminus W_n} \nu(A) \leq \gamma.
\]

Using lemma A.1 we have that
\[
\begin{align*}
    h(\nu) &\leq \frac{1}{m_n} \sum_{A \in W_n} -\nu(A) \log \nu(A) + \frac{1}{m_n} \sum_{A \in \mathcal{P}^{(m_n)} \setminus W_n} -\nu(A) \log \nu(A) \\
    &\leq \frac{1}{m_n} (1 + (1 - \tilde{\gamma}_n) \log \#W_n) + \frac{1}{m_n} (1 + \gamma \log \#\mathcal{P}^{(m_n)}).
\end{align*}
\]

Using (24), observe that since \(\frac{\theta_m}{\lambda m} < \varepsilon_0\) for any \(y \in L_n\) there is a branch \(g\) of the inverse of \(T^{m_n}\) such that the ball
\[
B(y, \theta_m) \subseteq g(B(T^{m_n}y, \varepsilon_0)).
\]

Since \(\mathcal{P}\) is a Markov partition with \(\text{diam} \mathcal{P} < \varepsilon_0\),
\[
\mathcal{P}^{m_n} = \{ g(A) \mid A \in \mathcal{P}, \ g \text{ is branch of } T^{-m_n} \}.
\]

Therefore the ball \(B(y, \theta_m)\) intersects at most \(#\mathcal{P}\) elements of \(\mathcal{P}^{m_n}\) because by applying \(T^{m_n}\)
\[
\#\{ B \in \mathcal{P}^{m_n} \mid B \cap B(y, \theta_m) \neq \emptyset \} \leq \#\{ A \in \mathcal{P} \mid A \cap B(T^{m_n}y, \varepsilon_0) \neq \emptyset \} \leq \#\mathcal{P}.
\]

Since \(L_n\) has at most \(n\) elements, \(#W_n \leq n \#P\). Thus from (25) and (27) we have that
\[
\begin{align*}
    h(\nu) &\leq \frac{1}{m_n} (1 + (1 - \tilde{\gamma}_n) \log n \#\mathcal{P}) + \frac{1}{m_n} (1 + \gamma \log \#\mathcal{P}^{(m_n)}) \\
    &\leq \frac{2 + \log \#\mathcal{P}}{m_n} + \frac{\log n}{m_n} + \frac{\gamma}{m_n} \log \#\mathcal{P}^{(m_n)} < 2\gamma h_{\text{top}}(T).
\end{align*}
\]

This proves the claim.

**Step 5.** We now complete the proof. Define a sequence of functions \(f_n \in \text{Lip}(X, \mathbb{R})\) by
\[
(28) \quad f_n(x) = f(x) + \beta - \beta d(x, L),
\]

where \(L_n = \text{supp} \mu_n\) as above. From the definition of \(\beta\) we have that \(f_n \in U\) for each \(n \geq 1\). From step 3 we have that
\[
\int d(x, K) \, d\mu_n = o(\theta_m),
\]

and from step 4 it follows that when \(n\) is sufficiently large,
\[
\int d(x, L_n) \, d\nu \geq \theta_m \nu(\{ x \in X \mid d(x, L_n) \geq \theta_m \}) \geq \gamma \theta_m.
\]
for all $\nu \in \mathcal{M}(T)$ such that $h(\nu) \geq 2\gamma h_{\text{top}}(T)$.

We may therefore choose $n$ such that $\beta \int d(x, L_n) \, d\nu > C \int d(x, K) \, d\mu_n$ for every $\nu \in \mathcal{M}(T)$ such that $h(\nu) \geq 2\gamma h_{\text{top}}(T)$. It follows that for every such measure $\nu$

$$\int f_n \, d\nu = \int f \, d\nu + \beta \int d(x, L_n) \, d\nu$$

$$< -\alpha(f) - C \int d(x, K) \, d\mu_n + \beta$$

$$\leq \int f \, d\mu_n + \beta = \int f_n \, d\mu_n \leq -\alpha(f_n),$$

where we have applied (22) and (28). We have shown that if $\nu \in \mathcal{M}(T)$ and $h(\nu) \geq 2\gamma h_{\text{top}}(T)$, then $\nu \notin \mathcal{M}_{\text{max}}(f_n)$, and therefore $f_n \in \mathcal{E}_\gamma \cap U$. We conclude that $\mathcal{E}_\gamma$ is dense in Lip$(X, \mathbb{R})$ and the theorem is proved.
