A Bijective Proof of a False Theta Function Identity from Ramanujan’s Lost Notebook

Dedicated to Professor George Andrews on the occasion of his eightieth birthday

Hannah E. Burson

Abstract. In his lost notebook, Ramanujan listed five identities related to the false theta function:

$$f(q) = \sum_{n=0}^{\infty} (-1)^n q^{(n+1)/2}.$$ 

A new combinatorial interpretation and a proof of one of these identities are given. The methods of the proof allow for new multivariate generalizations of this identity. Additionally, the same technique can be used to obtain a combinatorial interpretation of another one of the identities.

Mathematics Subject Classification. Primary 05A17; Secondary 05A19.

Keywords. Partitions, Overpartitions, False theta functions.

1. Introduction

Rogers [16] introduced false theta functions, which are series that would be classical theta functions except for changes in signs of an infinite number of terms. In his notebooks [14] and the lost notebook [15], Ramanujan recorded many false theta function identities that he discovered. However, in Ramanujan’s last letter to Hardy in 1920, Ramanujan introduced mock theta functions and shifted his focus away from false theta functions. The mathematical community followed Ramanujan’s lead and largely ignored false theta functions for the next several decades.

In recent times, there has been an increase in interest in false theta functions. G.E. Andrews devoted a section of [3] to partition theoretic applications of false theta functions. More recently, such as in [1, 2, 9, 10, 13], researchers have found combinatorial proofs of some of Ramanujan’s false theta function identities.
In his lost notebook [15] (cf. [5, p. 227]), Ramanujan stated five identities related to the false theta function:

\[ f(q) = \sum_{n=0}^{\infty} (-1)^n q^{n(n+1)/2}, \quad |q| < 1. \]  

(1.1)

These identities were first proved by Andrews in [4], using identities such as the Rogers–Fine identity and Heine’s transformation. Other analytic proofs have been given in [7,11,17]. There are no previously known bijective proofs of any of these identities.

In this paper, we adopt the standard \( q \)-series notation:

\[ (a; q)_n = \prod_{j=0}^{n-1} (1 - aq^j), \quad |q| < 1, n \in \{0, 1, 2 \ldots \}. \]

We will focus on a bijective proof of Ramanujan’s identity for \( f(q^4) \).

**Theorem 1.1.** (Ramanujan) If \( f(q) \) is defined by (1.1), then for \( |q| < 1 \):

\[ \sum_{n=0}^{\infty} \frac{(q; q^2)_n q^n}{(-q^2; q^2)_{n+1}} = f(q^4). \]

The combinatorial interpretation of this identity has several similarities to the combinatorial version of Euler’s pentagonal number theorem, which was bijectively proved by Franklin [12]. Since the function in the pentagonal number theorem is a theta function, these similarities are not obvious analytically.

In Sect. 2, we explain the necessary background on partitions. Then, in Sect. 3, we introduce a new combinatorial analog of Theorem 1.1 and give its bijective proof in Sect. 4. In Sect. 5, we introduce new identities that arise from generalizing the proof in Sect. 4. Finally, in Sect. 6, we give a similar combinatorial interpretation of another one of Ramanujan’s identities.

**2. Background**

We use several tools from the theory of partitions. Recall that a partition of \( n \) is a non-increasing sequence of integers \( (\pi_1, \pi_2, \ldots, \pi_k) \), where \( \pi_1 + \pi_2 + \cdots + \pi_k = n \). An overpartition of \( n \) is a partition of \( n \) where the first appearance of a part of any size may be overlined. For example, \( (7, 6, 5, 5, 5, 3, 2, 2, 2) \) is an overpartition of 37. We can create a graphical representation of a partition, called a Ferrers diagram, by making an array of boxes whose \( i \)th row has as many boxes as the \( i \)th part of the partition. There is a variation of a Ferrers diagram called an \( m \)-modular diagram (also called a MacMahon diagram) where the part \( mj + r \) with \( 0 \leq r < m \) is represented by a row made of \( j \) boxes containing an \( m \) following one box containing an \( r \).

For this paper, we create an analog of a two-modular diagram called a boxed two-modular diagram, which is a graphical representation of a pair \( (k, \pi) \) where \( k \) is a non-negative integer and \( \pi \) is a partition. To obtain the boxed two-modular diagram, we represent \( \pi \) as a two-modular diagram and \( k \)
as a row of one 0 and $k$ 1s at the top of the diagram. For example, the figure below is a boxed two-modular diagram for the pair $(3, (8, 7, 5, 5, 3))$:

```
0 1 1 1
2 2 2 2
1 2 2 2
1 2 2
1 2
```

Note that, if $\pi$ is a partition into odd parts with the largest part no greater than $2k + 1$, the boxed 2-modular diagram will have the shape of a partition and the boxes in the first column will not contain any 2s. In this case, our boxed two-modular diagram is exactly the odd Ferrers graph introduced in [6] and named in [8].

To represent an overpartition, we add a shaded box to the end of any overlined part. Note that, to maintain the general shape of a Ferrers diagram, we must require that any overlined part be no larger than $2k - 1$. For example, the figure below is a boxed 2-modular diagram for the pair $(3, (8, 7, 5, 5, 3))$:

```
0 1 1 1
2 2 2 2
1 2 2 2
1 2 2
1 2
```

We use the following notation when discussing pairs $(k, \pi)$.
- $P_n$ is the set of pairs $(k, \pi)$ where $k$ is a non-negative integer and $\pi$ is an overpartition of $n - k$ into odd parts of size no greater than $2k + 1$ and with all overlined parts of size no greater than $2k - 1$.
- $\nu(\pi)$ is the number of parts of the overpartition $\pi$.
- $s(\pi)$ is the size of the smallest part of $\pi$.
- $\nu(\ell)(k, \pi)$ is the number of parts of size $2k + 1$ in $\pi$.
- $\nu_s(\pi)$ is the number of times the smallest part appears in $\pi$.

### 3. Combinatorial Interpretation

In this section, we interpret Theorem 1.1 in terms of pairs $(k, \pi) \in P_n$. We count each pair $(k, \pi) \in P_n$ with weight $(-1)^{\nu(\pi)}$.

**Theorem 3.1.** Let $\overline{p}_o(n)$ (resp. $\overline{p}_e(n)$) be the number of pairs $(k, \pi)$, where $k$ is a non-negative integer and $\pi$ is an overpartition of $n - k$ into an odd number (resp. even number) of odd parts of size not exceeding $2k + 1$, where all overlined parts must have size $< 2k + 1$. Then, for $n \geq 0$:

$$
\overline{p}_e(n) - \overline{p}_o(n) = \begin{cases} (-1)^k, & \text{if } n = 2k(k + 1), \\ 0, & \text{otherwise}. \end{cases}
$$

**Theorem 3.2.** Theorems 1.1 and 3.1 are equivalent.
Proof. The equivalence of the right sides is trivial, so we focus on the left sides. Note that \((q; q^2)_k\) generates partitions into distinct odd parts of size no greater than \(2k - 1\), where each partition into \(\nu\) parts has weight \((-1)^\nu\). Similarly, \(\frac{1}{(-q; q^{-2})_{k+1}}\) generates partitions into odd parts of size no greater than \(2k + 1\), where each partition into \(\nu\) parts has weight \((-1)^\nu\). Thus, if we let the parts coming from \((q; q^2)_k\) be overlined, we find that \((q; q^2)_k\) \((-q; q^{-2})_{k+1}\) generates overpartitions into odd parts of size no greater than \(2k + 1\), where all overlined parts are no larger than \(2k - 1\), and each overpartition into \(\nu\) parts is counted with weight \((-1)^\nu\). Additionally, \(q^k\) generates the integer \(k\). Therefore

\[
\sum_{k=0}^{\infty} (q; q^2)_k q^k = \sum_{n=0}^{\infty} [p_e(n) - p_o(n)] q^n,
\]

where \(p_e(n)\) and \(p_o(n)\) are as defined in Theorem 3.1.

\[\Box\]

4. Proof of the Main Theorem

We devote this section to proving Theorem 3.1 combinatorially. To obtain the bijection, we split \(\mathcal{P}_n\) into cases. First, we show that conjugation is a sign-reversing involution on the case where \(k + \nu(\pi) \equiv 1 \pmod{2}\). Then, for the case where \(k + \nu(\pi) \equiv 0 \pmod{2}\), we further divide this subset of \(\mathcal{P}_n\) into cases depending on the relative sizes of the last row and the last column of the boxed 2-modular diagram and introduce variations of the conjugation that provide sign-reversing bijections and involutions on these cases.

4.1. Conjugation

For an ordinary partition \(\pi\), the conjugate partition \(\pi'\) is defined to be the partition created by reflecting the Ferrers diagram of \(\pi\) about the line \(y = -x\). Similarly, for a pair \((k, \pi)\), where \(k\) is a non-negative integer and \(\pi\) is a partition into odd parts of size \(\leq 2k + 1\), we can reflect our boxed 2-modular diagram about the line \(y = -x\) to get the conjugate pair \((k', \pi')\).

Example 4.1. The conjugate of \((4, (9, 9, 7, 7, 5, 5, 3))\) is \((7, (15, 13, 9, 5))\):

\[
\begin{array}{cccccc}
0 & 1 & 1 & 1 & 1 & 0 \\
1 & 2 & 2 & 2 & 2 & 1 \\
1 & 2 & 2 & 2 & 2 & 1 \\
1 & 2 & 2 & 2 & 1 & 2 \\
1 & 2 & 2 & 1 & 2 & 2 \\
1 & 2 & 1 & 2 & 1 & 2 \\
1 & 2 & 1 & 2 & 1 & 2 \\
1 & 2 & 1 & 2 & 1 & 2 \\
1 & 2 & 1 & 2 & 1 & 2 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{cccccc}
0 & 1 & 1 & 1 & 1 & 1 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 & 2 & 2 \\
\end{array}
\]

Furthermore, we note that conjugation generalizes to the overpartition case. Specifically, we let \((k', \pi')\) be the conjugate partition of the pair \((k, \pi)\) \(\in\mathcal{P}_n\). Then, for every \(j\), where a part of size \(2j + 1\) is overlined in \(\pi\), the \((j + 1)^{st}\) part in \(\pi'\) must be overlined.

Example 4.2. The conjugate of \((3, (7, 5, 5, 3, 1, 1, 1))\) is \((8, (11, 9, 3))\):

\[
\begin{array}{cccc}
0 & 1 & 1 & 1 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
\end{array}
\quad \rightarrow \quad
\begin{array}{cccc}
0 & 1 & 1 & 1 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
1 & 2 & 2 & 2 \\
\end{array}
\]
Note that, because conjugation swaps rows and columns and preserves the boxes in the diagram, $k' = \nu(\pi)$, $\nu(\pi') = k$, and $k' + |\pi'| = k + |\pi|$. Furthermore, since conjugation is its own inverse, we obtain the following lemma.

**Lemma 4.3.** Let $S_{n,k,\ell}$ be the set of pairs $(k, \pi)$, where $k$ is a non-negative integer and $\pi$ is an overpartition of $n - k$ into $\ell$ odd parts of size $\leq 2k + 1$, with all overlined parts no larger than $2k - 1$. Then, $|S_{n,k,\ell}| = |S_{n,\ell,k}|$.

When $k + \nu(\pi) \equiv 1 \pmod{2}$, conjugation is sign-reversing, which leads to the next lemma.

**Lemma 4.4.** Conjugation is a sign-reversing involution on pairs $(k, \pi) \in P_n$ counted with weight $(-1)^{\nu(\pi)}$, when $k + \nu(\pi) \equiv 1 \pmod{2}$.

**Proof.** This follows from Lemma 4.3 and the fact that $k \not\equiv \nu(\pi) \pmod{2}$, so conjugation must be sign-reversing. \qed

### 4.2. Variations

For the case $k + \nu(\pi) \equiv 0 \pmod{2}$, we consider two variations of conjugation. First, we define $\phi_s(k, \pi)$ by fixing the last row of the boxed two-modular diagram for $(k, \pi)$ and conjugating the remainder of the diagram.

**Example 4.5.** $\phi_s(4, (9, 9, 9, 7, 7, 5)) = (5, (11, 11, 11, 7, 5))$

Note that $\phi_s$ is well defined for pairs $(k, \pi) \in P_n$ where the last row of the boxed two-modular diagram is shorter than the last column. Equivalently, $\phi_s$ is well defined when $\frac{s(\pi) - 1}{2} < \nu(\ell(k, \pi))$. Furthermore, $\phi_s$ is also well defined when $\frac{s(\pi) - 1}{2} = \nu(\ell(k, \pi))$, $s(\pi) < 2k + 1$, and the last part of $\pi$ is not overlined. The last condition is necessary to maintain the restriction on overpartitions that only the first part of any size may be overlined. If we define $(k_s, \pi_s) = \phi_s((k, \pi))$, we can note that $k_s = \nu(\pi) - 1$ and $\nu(\pi_s) = k + 1$. Moreover, the size of the penultimate part of $\pi$ determines $\nu(\ell(\phi_s(k, \pi)))$, so we consider separately the cases where $\nu_s(\pi) = 1$ and $\nu_s(\pi) > 1$. Then, we have the following lemmas.
Lemma 4.6. The map \( \phi_s \) is a sign-reversing involution on the set \( \{ (k, \pi) \in \mathcal{P}_n : k + \nu(\pi) \equiv 0 \pmod{2}, s(\pi) < 2\nu(k, \pi) + 1, \text{ and } \nu_s(\pi) = 1 \} \).

Proof. Let \( (k, \pi) \in \mathcal{P}_n \), such that \( k + \nu(\pi) \equiv 0 \pmod{2}, s(\pi) < 2\nu(k, \pi) + 1 \), and \( \nu_s(\pi) = 1 \). Let \( (k_s, \pi_s) = \phi_s(k, \pi) \). Since \( \nu_s(\pi) = 1 \), the second smallest part of \( \pi \), which determines \( \nu(k_s, \pi_s) \), will be larger than \( s(\pi) = s(\pi_s) \), so \( s(\pi_s) < 2\nu(k, \pi_s) + 1 \). Moreover, since \( s(\pi) < 2\nu(k, \pi) + 1, \nu_s(\pi) = 1 \). Thus, \( (k_s, \pi_s) \in \mathcal{P}_n, k_s + \nu(\pi_s) \equiv 0 \pmod{2}, s(\pi_s) < 2\nu(k_s, \pi_s) + 1, \text{ and } \nu_s(\pi_s) = 1 \). Finally, since \( \nu(\pi) \equiv k \not\equiv k + 1 \pmod{2} \) and \( \nu(\pi_s) = k + 1, \nu(\pi_s) \neq \nu(\pi) \pmod{2} \), so the map is sign-reversing. \( \square \)

Lemma 4.7. The map \( \phi_s \) is a sign-reversing involution on the set \( \{ (k, \pi) \in \mathcal{P}_n : k + \nu(\pi) \equiv 0 \pmod{2}, s(\pi) = 2\nu(k, \pi) + 1, s(\pi) \neq 2k + 1, \text{ and } \nu_s(\pi) > 1 \} \).

Proof. Let \( (k, \pi) \in \mathcal{P}_n \), such that \( k + \nu(\pi) \equiv 0 \pmod{2}, s(\pi) = 2\nu(k, \pi) + 1 \), \( s(\pi) \neq 2k + 1 \) and \( \nu_s(\pi) > 1 \). Since \( s(\pi) \neq 2k + 1, \phi_s \) is well defined and we can let \( (k_s, \pi_s) = \phi_s(k, \pi) \). Since \( \nu_s(\pi) > 1, 2\nu(k_s, \pi_s) + 1 = s(\pi) = s(\pi_s) \). Furthermore, because \( s(\pi) \neq 2k + 1 \) and \( \nu_s(\pi) > 1, \nu(k, \pi_s) < \nu(\pi) - 1 \), we have \( s(\pi_s) = s(\pi) = 2\nu(k, \pi) + 1 < 2\nu(\pi) - 1 = 2k_s + 1 \). Moreover, since \( s(\pi) = 2\nu(k, \pi) + 1, \nu_s(\pi_s) > 1 \). Thus, \( (k_s, \pi_s) \in \mathcal{P}_n, k_s + \nu(\pi_s) \equiv 0 \pmod{2}, s(\pi_s) = 2\nu(k_s, \pi_s) + 1, s(\pi_s) \neq 2k + 1, \text{ and } \nu_s(\pi_s) > 1 \). Finally, as explained above, the map is sign-reversing, because \( \nu(\pi_s) \neq \nu(\pi) \pmod{2} \). \( \square \)

Another variation of conjugation is \( \phi_r \), defined as \( \phi_r(k, \pi) = \text{conj} \circ \phi_s \circ \text{conj}(k, \pi) \), where conj is the conjugation map described in Sect. 4.1. Note that this is the same as fixing the right-most column of the boxed 2-modular diagram, and conjugating the remainder.

Example 4.8. We have \( \phi_r(5, (11, 11, 9, 9, \overline{7}, 7, 7)) = (8, (17, 17, 15, \overline{9})) \).

Note that \( \phi_r \) is well defined for pairs \( (k, \pi) \in \mathcal{P}_n \) where the last row of the boxed 2-modular diagram is longer than the last column. Equivalently, \( \phi_r \) is well defined when \( \frac{s(\pi) - 1}{2} > \nu(k, \pi) \). Thus, we obtain the following lemma.

Lemma 4.9. The map \( \phi_r \) is a sign-reversing involution on the set \( \{ (k, \pi) \in \mathcal{P}_n : k + \nu(\pi) \equiv 0 \pmod{2}, s(\pi) > 2\nu(k, \pi) + 1, \text{ and } \pi \text{ has a part of size } 2k - 1 \} \).
Proof. Let \((k, \pi) \in \mathcal{P}_n\), such that \(k + \nu(\pi) \equiv 0 \pmod{2}\), \(s(\pi) > 2\nu(\ell(k, \pi)) + 1\), and \(\pi\) has a part of size \(2k-1\). Let \((k', \pi')\) be the conjugate of \((k, \pi)\). Then, \(s(\pi') < 2\nu(\ell(k', \pi')) + 1\) and \(\nu_s(\pi) = 1\), so we can apply Lemma 4.3. □

After applying Lemmas 4.4, 4.6, 4.7, and 4.9, we are left with four cases, all of which have \(k + \nu(\pi) \equiv 0 \pmod{2}\).

- **Case 1:** The smallest part of \(\pi\) appears once and is equal to \(2\nu(\ell(k, \pi)) + 1 \neq 2k + 1\).
- **Case 2:** The smallest part of \(\pi\) appears multiple times and is smaller than \(2\nu(\ell(k, \pi)) + 1\).
- **Case 3:** The smallest part of \(\pi\) is greater than \(2\nu(\ell(k, \pi)) + 1\) and \(\pi\) has no part of size \(2k - 1\).
- **Case 4:** \(s(\pi) = 2\nu(\ell(k, \pi)) + 1 = 2k + 1\).

Note that applying \(\phi_s\) to a pair \((k, \pi)\) in Case 1 reduces the number of distinct parts by one. Since the number of overpartitions of a given shape depends on the number of distinct parts, reducing the number of distinct parts by one requires us to restrict which parts of \(\pi\) may be overlined. The next two lemmas provide the details of dividing Case 1 into two halves by considering whether or not the smallest part is overlined.

**Lemma 4.10.** There is a sign-reversing bijection between the pairs in Case 1 where the smallest part is not overlined and the pairs in Case 2.

**Proof.** Let \((k, \pi)\) be a pair in Case 1 where the smallest part of \(\pi\) is not overlined. Since the smallest part of \(\pi\) is not overlined, \(\phi_s\) is well defined. Thus, let \((k_s, \pi_s) = \phi_s(k, \pi)\). Since \(\nu_s(\pi) = 1\), \(s(\pi_s) < 2\nu(\ell(k_s, \pi_s)) + 1\). Moreover, because \(s(\pi) = 2\nu(\ell(k, \pi)) + 1\), \(\nu_s(\pi_s) > 1\). Therefore, \((k_s, \pi_s)\) is in Case 2.

Since \(\phi_s\) is its own inverse, we can take a pair \((k_2, \pi_2)\) in Case 2 and apply \(\phi_s\) to find a pair in Case 1. Because \(\pi_2\) has more than one appearance of the smallest part, the last part will not be overlined, so the smallest part of \(\phi_s(k_2, \pi_2)\) will not be overlined. □

**Lemma 4.11.** There is a sign-reversing bijection between the pairs in Case 1, where the smallest part is overlined, and the pairs in Case 3.

**Proof.** Note that conjugation is a sign-preserving bijection between the pairs in Case 2 and the pairs in Case 3. Thus, we can remove the overline on the smallest part of \(\pi\), apply \(\phi_s\), and take the conjugate to obtain a sign-reversing bijection between the pairs in Case 1, where the smallest part is overlined, and the pairs in Case 3. □

Now, the only pairs left are those in Case 4. These occur exactly when \(n = k + |\pi| = 2k(k + 1)\), proving Theorem 3.1.

### 5. Generalizations

First, we note that all of our maps preserve the number of boxes containing a 1 in our diagrams. Furthermore, this number of 1s is exactly \(k + \nu(\pi)\). Thus, if we let \(z\) count the number of 1s in the diagram, we obtain a generalization:
Theorem 5.1. \[
\sum_{n=0}^{\infty} \frac{(zq^r;q^2)_n z^n q^n}{(-zq^r;q^2)_{n+1}} = \sum_{n=0}^{\infty} (-1)^n z^{2n} q^{2n(n+1)}.\]

Theorem 1.1 is the case \(z = 1\) of this generalization. Additionally, we can generalize boxed two-modular diagrams as boxed \(m\)-modular diagrams by replacing the 2s in the diagram with \(m\)'s and all 1s with \(r\)'s to allow parts of size \(r \pmod{m}\) for some fixed \(0 \leq r < m\). Then, we obtain the following generalization:

Theorem 5.2. \[
\sum_{n=0}^{\infty} \frac{(zq^r;q^m)_n z^n q^{rn}}{(-zq^r;q^m)_{n+1}} = \sum_{n=0}^{\infty} (-1)^n z^{2n} q^{n(mn+2r)},
\]

Theorem 5.2 yields Theorem 1.1 when \(z = 1\), \(m = 2\), and \(r = 1\). Analytically, Theorem 5.2 follows from the Rogers–Fine identity.

6. Further Work

This work allows us to obtain a similar combinatorial interpretation for another one of Ramanujan’s identities.

Theorem 6.1. (Ramanujan) If \(f(q)\) is defined by (1.1), then for \(|q| < 1\):

\[
\sum_{k=0}^{\infty} \frac{q^k (q_1^2)}{(-q_1)^{2k+1}} = f(q^3).
\]

We can interpret Theorem 6.1 in terms of pairs \((k, \pi)\) in \(P'_n\) where \(P'_n\) contains all pairs \((k, \pi)\) where \(k \in \mathbb{Z}_{\geq 0}\), \(\pi\) is an overpartition into parts of size \(\leq 2k+1\) where all overlined parts are odd and of size \(\leq 2k-1\), and \(k + |\pi| = n\). We count each pair with weight \((-1)^{\nu(\pi)}\).

Theorem 6.2. Let \(P'_o(n)\) (resp. \(P'_e(n)\)) be the number of pairs \((k, \pi)\) in \(P'_n\) where \(\pi\) has an odd number (resp. even number) of parts. Then, for \(n \geq 0\):

\[
P'_e(n) - P'_o(n) = \begin{cases} (-1)^k, & \text{if } n = \frac{3k(k+1)}{2}, \\ 0, & \text{otherwise}. \end{cases}
\]

Due to the presence of even parts in the partition, a bijective proof of Theorem 6.2 appears to be more difficult than the proof of Theorem 3.1 and would be a welcome contribution. We suspect that the involution necessary for a bijective proof of Theorem 6.2 will fix pairs \((k, (2k + 2k - 1 + \cdots + (k + 1)))).

Acknowledgements

The author would like to thank Bruce Berndt for suggesting this project, and also thank Frank Garvan for suggesting Theorem 5.1 and Dennis Eichhorn for his many helpful comments.
