1 | INTRODUCTION

The initial definitions, that sepsis is caused by a host's systemic inflammatory response syndrome (SIRS) to infection, was developed in a 1991 consensus conference (Members of the American College of Chest Physicians/Society of Critical Care Medicine Consensus Conference Committee, 1992). In 2016, it is defined as life-threatening organ dysfunction...
arising from a dysregulated host response to infection (Singer et al., (2016)). In some cases, many of the components of the innate immune response can lead to cell and tissue damage, and even multiple organ failure, the clinical hallmark of sepsis (Cohen, (2002)). The development of sepsis inflammatory injury is a complex process, in which abnormal structure and expression of many encoding genes or non-coding genes exist (Sun et al., 2017). Similarly to acute myocardial infarction or stroke, early detection during the first few hours of sepsis improves outcomes (Rhodes et al., 2017). Due to the high mortality of sepsis, many efforts have been made to help understand the dysregulation of the host response in sepsis.

Considerable evidences suggest that long noncoding RNAs (lncRNAs) are RNA species >200 bp in length and frequently polyadenylated (Guttman et al., 2009; Prensner & Chinnaiyan, 2011). Abundant lncRNAs which are associated with various biological functions have been identified with whole genome transcriptomic analyses (Wang, Han, et al., 2014; Wang et al., 2015). LncRNA is closely related to some pathological process, which was reported to exert great influence in the regulation of chondriokinesis, cell-type determination and tissue homeostasis, pro-inflammatory cytokines, calcium ion transport, nuclear factor-xB (NF-xB) in signal pathway, and other inflammatory lesions (Carpenter et al., 2013; Gupta et al., 2010; Magny et al., 2013; Rapicavoli et al., 2013; Wang, Long, et al., 2014). As per competing endogenous RNA (ceRNA) hypothesis, lncRNAs exert momentous roles in various biological processes by competing miRNAs with mRNAs to attenuate the inhibition ability of miRNAs to mRNAs (Salmena et al., (2011)). Several studies have described the lncRNA profile in sepsis, but the lncRNA landscape in septic patients remains to be explored (Dai et al., 2017; Lin et al., 2015; Mayama et al., 2016).

We previously identified expression profiles of miRNA and mRNA in septic patients by RNA-sequencing and bioinformatics analysis (Qin et al., 2020). Currently, we aimed to further investigate lncRNAs associated with sepsis by RNA-sequencing and constructing a ceRNA (lncRNA-miRNA-mRNA) network. Combined with the mRNA profiles, we obtained previously, an integrated analysis of mRNA expression profiles downloaded from Gene Expression Omnibus (GEO) database was performed to obtain the differentially expressed mRNAs (DEmRNAs) between septic patients and healthy controls. Based on differentially expressed lncRNAs (DElncRNAs) and DEmRNAs acquired in this present study and differentially expressed miRNAs (DEmiRNAs) acquired in previous study, a ceRNA network was constructed.

2 MATERIALS AND METHODS

2.1 Ethical compliance

This study was approved by the Ethics Committee of The Third Hospital of Hebei Medical University (2018-021-1).

2.2 Data sets collection

To acquire mRNA expression profiles of sepsis, data sets in GEO were retrieved. Five data sets, including GSE69528, GSE67652, GSE57065, GSE26378, and GSE26440, were downloaded from GEO (Table 1).

2.3 Patients and samples

Three septic patients and three healthy controls were recruited to obtain lncRNA expression profiles in this current study. Every participant provided written informed consent for use of their samples. A 2.5 ml peripheral whole blood from every individual was collected in PAXgene® RNA blood tubes (PreAnalytiX GmbH) and stored at −80°C prior to processing. RNA isolation was performed with PAXgene blood RNA kit (PreAnalytiX GmbH). Sequencing was performed based on the Illumina Hiseq X-ten platform (Illumina, Inc.). The GRCh38 was used as the reference genome sequence.

### Table 1 List of mRNA study samples from GEO.

| GEO ID     | Author | Platform | Samples (N:P) | Country | Year |

2.4 Identification of DEmRNAs and DElncRNAs

MetaMA was applied to obtain the DEmRNAs based on the mRNA expression profiles downloaded from GEO and mRNAs we identified previously. The threshold for the significance of DEmRNAs was \( p < .05 \). As Zhou et al., (2018) described, differentially expressed IncRNAs (DElncRNAs) were acquired with false discovery rate (FDR) <0.01. By using R package “pheatmap,” hierarchical clustering analysis of DElncRNAs and DEmRNAs was performed.

2.5 Functional enrichment of DEmRNAs

With GeneCodis3 (http://genecodis.cnbc.es/analysis), Gene Ontology (GO) classification and Kyoto Encyclopedia of Genes and Genomes (KEGG) pathway enrichment analysis of DEmRNAs were conducted. Statistical significance was defined as \( p < .05 \).

2.6 Protein-protein interaction (PPI) network construction

All DEmRNAs were searched with the BioGrid (http://www.uniprot.org/database/DB-0184), and PPI network was visualized with Cytoscape software (version 3.6.1, http://www.cytoscape.org).

2.7 Construction of the ceRNA (DElncRNA-DEmiRNA-DEmRNA) regulatory network

Based on miRTarBase, DEmiRNA-DEmRNA pairs were acquired. With starBase, DElncRNA-DEmiRNA interaction pairs were obtained as well. According to ceRNA theory, the ceRNA (DElncRNA-DEmiRNA-DEmRNA) regulatory network was constructed with Cytoscape 3.5.1 (http://cytoscape.org/), by combining IncRNA-miRNA pairs and miRNA-mRNA pairs.

2.8 Cell culture and transfection

Human monocytes THP-1 was purchased from National Infrastructure of Cell Line Resource (Beijing, China) and cultured in Roswell Park Memorial Institute (RPMI)-1640 medium supplemented with 10% fetal bovine serum (FBS) in a 5% CO₂ incubator at 37°C. Cells were treated by 10 μg/mL LPS for 24 h to induce sepsis cell model. siRNAs against LINC00963 and negative controls were purchased from GenePharma. Cell transfection was conducted using Lipofectamine 2000 reagent (Thermo Fisher Scientific, Waltham, MA, USA) according to the manufacturer’s protocol. Culture medium was replaced after transfection 4–6 h. After incubation for 24 h, they were collected for further analyses.

2.9 CCK-8 assay

The cell proliferation was examined using the CCK-8 assay kit according to the manufacturer’s instructions. THP-1 cells in the logarithmic growth phase were selected and planted into 96-well plates at a density of 5 × 10^4 (Cohen, 2002) cells per well with three replicates per condition. At 0, 24, 48, and 72 h, 10 μl CCK-8 solution was added to each well. After incubation with CCK-8 solution for 4 h, the absorbance value at 450 nm was measured using a microplate reader (Thermo Fisher Scientific).

2.10 Quantitative reverse transcription PCR assay

Total RNA was extracted using TRIzol reagent (Invitrogen) according to the manufacturer’s instructions. Quantitative reverse transcription PCR (qRT-PCR) was performed using a SYBR Green QPCR Supermix (Bio-rad). The primer sequences were as follows: tumor necrosis factor-α (TNF-α) F: 5′-CAGCCTCTTCTCTTCTCTTGTA-3′, R: 5′-GGAAGACCCCTCCAGAGATA-3′; CCL2 F: 5′-GCCTATAGCAGCACCTATCCTC-3′, R: 5′-CGGCCAAATAAACCGATGTGATAC-3′; interleukin (IL)-1β F: 5′-GCAACTGTTCCTGAACTCAACT-3′; Caspase1 (CASP1) F: 5′-ACGCCTTGCCCTCATAAT-3′, R: 5′-GGCTGTTGATCCCTCAGACCC-3′; GAPDH (F: 5′-GGAGGGAGATCCCTCCAAAAT-3′, R: 5′-GGCTGTGTTGATCCCTCAGACCC-3′) was used as an internal reference gene. The result of each sample was normalized by GAPDH and data were calculated by \( 2^{-ΔΔCt} \) method.

2.11 ELISA

ELISA was performed to detect the concentration of TNF-α, CCL2, IL-1β, NLRP3, and CASP1 in the culture medium of THP-1 cells using ELISA Kit (Abcam) according to the manufacturer's instructions.

2.12 Phagocytosis assay

According to the manufacturer's instructions, phagocytosis assay was performed. THP-1 cells suspension was prepared by centrifugation after trypsin digestion. Drop 400 μl cell
suspension onto a coverslip in a six-well plate. Then, 3 ml RPMI-1640 medium supplemented with 2% FBS was added after 4 h, followed by adding a fluorescent microsphere after 8 h and incubated for 24 h. Coverslips were washed with PBS three times, fixed with Carnoy's Fluid for 20 min, washed with PBS three times, and permeabilized with 0.1% Triton X-100 for 20 min. After washing with PBS, coverslips were treated with 1 mmol/l Dil solution for 20 min. Then, coverslips were mounted with Antifade Mounting Medium and visualized with a Confocal Microscope.

3 | RESULTS

3.1 | DEmRNAs and DElncRNAs between septic patients and healthy controls

Compared to healthy controls, a total of 290 DEmRNAs (117 upregulated and 173 downregulated DEmRNAs) and 46 DElncRNAs (39 upregulated and 7 downregulated DElncRNAs) were acquired in sepsis. The top 10 up- and downregulated DEmRNAs and DElncRNAs were exhibited in Tables 2 and 3, respectively. Hierarchical clustering analysis of DElncRNAs was shown in Figure 1.

3.2 | Functional enrichment of DEmRNAs

Respiratory electron transport chain ($p = 1.66E-08$), G1/S transition of mitotic cell cycle ($p = 1.50E-06$), nucleus ($p = 1.26E-20$), protein binding ($p = 4.58E-21$), and nucleic acid binding ($p = 2.06E-07$) were significantly enriched GO terms in sepsis (Figure 2a-c). Parkinson's disease ($p = 2.63E-10$), Oxidative phosphorylation ($p = 2.88E-10$), and Cardiac muscle contraction ($p = 5.50E-09$) were significantly enriched KEGG pathways in sepsis (Figure 2d).

3.3 | PPI network construction

The sepsis-specific PPI network included 114 nodes and 131 edges. XPO1 (degree = 26), CUL4A (degree = 10), and NEDD8 (degree = 9) were three hub proteins of sepsis-specific PPI network (Figure 3).

3.4 | CeRNA regulatory network

By combining DElncRNA-DEmiRNA pairs and DEmiRNA-DEmRNA pairs as mentioned above, the ceRNA network,

Abbreviations: DEmRNAs, differentially expressed mRNAs; FDR, false discovery rate.
which contained 16 DElncRNA-DEmiRNA pairs and 82 DEmiRNA-DEmRNA pairs, involving 5 lncRNAs, 10 miRNAs, and 60 mRNAs, was obtained (Figure 4).

### 3.5 Knockdown of LINC00963 promotes cell proliferation in THP-1 cells

To validate the analysis results, we chose an lncRNA termed LINC00963 for further investigation. In this study, LINC00963 was detected to be upregulated in sepsis. Then, LINC00963 was suppressed by siRNA in THP-1 cells. The effect of a reduced LINC00963 level on cell viability was determined by using CCK8 assay. THP-1 cells that were transfected with siRNA targeting LINC00963 showed significant increase in cell viability compared to the negative controls (Figure 5). This result demonstrated that knockdown of LINC00963 may promote cell proliferation in THP-1 cells.

### 3.6 Knockdown of LINC00963 reduces cytokine expression and suppresses inflammasome activation and phagocytosis in LPS-induced THP-1 cells

Compared to the control group, the mRNA levels of cytokine TNF, CCL2, and IL1β were significantly upregulated in LPS group (Figure 6a-c). Then, the concentration of cytokine TNF, CCL2, and IL1β were detected by ELISA as well. The results showed the markedly increase of these cytokines in the LPS group compared to the control group, as well as the significantly suppressed levels by knockdown of LINC00963 (Figure 7a-c). Thus, knockdown of LINC00963 could influence the concentration of TNF, CCL2, and IL1β, which may indicate that knockdown of LINC00963 inhibited the expression of TNF, CCL2, and IL1β in LPS-induced THP-1 cells. Subsequently, the degree of inflammasome activation, as indicated by the levels of NLRP3 and CASP1, was assessed. Both qRT-PCR and ELISA showed these two factors were significantly upregulated in the LPS group and significantly suppressed by knockdown of LINC00963, which suggested that knockdown of LINC00963 may suppress inflammasome activation in LPS-induced THP-1 cells. Finally, the phagocytosis activity of THP-1 cells was examined. As showed in Figure 8, the numbers of cells ingesting fluorescent microsphere was increased in LPS group, and decreased by knockdown of LINC00963. Hence, we speculated knockdown of LINC00963 could inhibit the phagocytosis activity of monocytes in the cell model of sepsis.

Table 3: Top 10 up- and downregulated DElncRNAs between patients with sepsis and normal controls.

Abbreviations: DElncRNAs, differentially expressed lncRNAs. FC, fold change. FDR, false discovery rate.

4 | DISCUSSION

Sepsis, a catastrophically amplified and dysregulated induction of pro-inflammatory cytokines often eventuating in multiorgan failure and death, is a major public health problem.
and a significant burden on the global healthcare system (Cohen, 2002; Edbrooke et al., 1999). Hence, it is of great importance to investigate key lncRNAs associated with the pathological mechanism of sepsis.

*UBAP2* (HGNC: 14185) encodes the protein ubiquitin-associated protein 2, a protein containing a UBA (ubiquitin-associated) domain characteristic of proteins that function in the ubiquitination pathway (Latonen et al., 2016). Abnormal *UBAP2* was detected in different cancers, such as hepatocellular carcinoma (HCC) and prostate cancer (PC; Bai et al., 2016; Latonen et al., 2016). Substantial evidences suggest that the ubiquitin-proteasome pathway (UPP) may play roles in regulating intermediary metabolism and cell function in catabolic disease states, including sepsis (Patel et al., 2007). It is reported that UPP is a major protein degradation pathway that is modulated during sepsis (Jamart et al., 2014). However, to our best knowledge, there is no research linked *UBAP2* with sepsis. In current study, *UBAP2* was significantly downregulated in septic patients. Hence, we speculated that *UBAP2* may involve in the process of sepsis.

**Figure 1** The heatmap of DElncRNAs between sepsis and healthy controls. Row and column represented DElncRNAs and tissue samples, respectively. The color scale represented the expression levels.
FIGURE 2  Significantly enriched GO terms and KEGG pathways of DEmRNAs between sepsis and healthy controls. (a) BP, biological process; (b) CC, cellular component; (c) MF, molecular function; (d) KEGG pathways. The x-axis shows counts of DEmRNAs enriched in GO terms or KEGG pathways and the y-axis shows GO terms or KEGG pathways. The color scale represented -lg p-value.
Activin A receptor type 1 (ACVR1, HGNC: 171), also named as ALK2, is a bone morphogenetic protein (BMP) type I receptor and an important member of the BMP signaling pathway (Wang et al., 2018). Fibrodysplasia ossificans progressiva (FOP) is the most known ACVR1-related disorder (Rafati et al., 2016). In addition, it has been reported that ACVR1 not only functions in BMP signaling pathway, but also Wnt signaling pathway and plays critical roles in many diseases including breast cancer (Wang et al., 2018). In this study, ACVR1 was the most significantly downregulated DEmRNA and it may play key roles in sepsis.

Cytochrome c oxidase (COX) consists of three mitochondrial encoded proteins and 10 nuclear-encoded proteins, the latter of which including cytochrome c oxidase subunit 7B (COX7B, HGNC: 2291), to form the mature holocomplex in humans (Fontanesi et al., 2006). Over-expressed COX7B was detected in multiple diseases, such as, nasopharyngeal carcinoma, ovarian cancer, and Alzheimer’s disease (L’Esperance et al., 2006; Xiong et al., 2011; Zhang et al., 2015). As we all know, oxidative phosphorylation (OXPHOS) is an important biological process in mitochondria, and closely correlated to multiple neurodegenerative diseases, such as Parkinson’s disease, Alzheimer’s disease, and Huntington’s disease (Singh et al., 2019). Recently, mitochondrial dysfunction is increasingly recognized as an accomplice in most of the common human diseases, not only including cancer, neurodegeneration, but also diabetes, and sepsis (Lee & Huttemann, 2014). Substantial evidences suggest that the mitochondrial
OXPHOS system is a primary site of action during acute inflammation and inflammatory responses are key for the outcome of sepsis (Lee & Huttemann, 2014). Our study also indicated that COX7B is significantly upregulated and significantly enriched in Parkinson's disease, oxidative phosphorylation, Alzheimer's disease, and Huntington's disease. Hence, we speculated that COX7B might involve in sepsis through OXPHOS.

Previous studies linked LINC00963 (HGNC: 48716) with prostate cancer, hepatocellular carcinoma, and melanoma (Jiao et al., 2018; Wang, Han, et al., 2014; Wu et al., 2018). Chen et al., (2018) reported the effects of LINC00963 on renal interstitial fibrosis and oxidative stress of rats with chronic renal failure (CRF) through the Foxo signaling pathway, which is often complicated by sepsis. To validate our analyses results, the function of LINC00963 was investigated with a series of experiments in THP-1 cells. CCK8 assay demonstrated that knockdown of LINC00963 promotes cell proliferation in THP-1 cells. Both qRT-PCR and ELISA showed knockdown of LINC00963 inhibits cytokine expression and suppresses inflammasome activation in LPS-induced THP-1 cells. In addition, phagocytosis assay indicated that knockdown of LINC00963 inhibits the phagocytosis activity of monocytes in the cell model of sepsis. In our analysis,
LINC00963 acts as a ceRNA of UBAP2 via sponging hsa-miR-34a-5p, and a ceRNA of ACVR1 and COX7B via sponging hsa-let-7b-5p in ceRNA network, which may suggest that LINC00963 might involve in sepsis by ceRNA mechanism.

Acetylation of histone is an important epigenetic mechanism, regulated by two families of enzymes: histone deacetylases (HDACs) and histone acetyltransferases (HATs; Hawtree et al., 2013). Dysregulated HDAC activity is believed to be associated with the pathogenesis of inflammatory and autoimmune diseases (Hawtree et al., 2013). According to structure and function homology, 18 mammalian HDACs are classified as four different classes, including class I, II, III, and IV. In addition, class II HDACs are further subdivided into class IIa (HDAC4, 5, 7, and 9) and class IIb (HDAC6 and 10; Haberland et al., 2009).

As far as we know, HDAC6 (HGNC: 14064) is a unique HDAC and is found primarily in cytoplasm (Valenzuela-Fernandez et al., 2008). It is reported that HDAC6 promotes inflammation by regulating expression of genes involved in inflammatory responses (Yan et al., 2018). It had been reported that inhibition of HDAC6 resulted in the amelioration of lupus nephritis in lupus-prone mice (Vieson et al., 2017). In a lethal septic model, Tubastatin A, a selective inhibitor of HDAC6, was demonstrated to significantly improve long-term survival, which indicated the therapeutic significance of selective inhibition of HDAC6 for sepsis (Li et al., 2015). Recently, Guo et al. demonstrated that HDAC6 promotes sepsis development by impairing PHB1-mediated mitochondrial respiratory chain function (Guo et al., 2020).

PAX8-AS1 (HGNC: 49271) is located on chromosome 2q13 in the upstream region of PAX8 (Han et al., 2016). Expression level of PAX8-AS1 was significantly correlated to thyroid cancer patients overall or recurrence-free survival time (Lu et al., 2018). Two variants of PAX8-AS1 were reported to decrease the risk of cervical cancer (Han et al.,

**FIGURE 5** CCK8 assay showed that LINC00963 knockdown by siRNA promoted the proliferation of THP-1 cells.

**FIGURE 6** QRT-PCR analysis of TNF, CCL2, IL1β, NLRP3, and CASP1 in LPS-induced THP-1 cells.
**Figure 7** ELISA assay of TNF, CCL2, IL1β, NLRP3, and CASP1 in LPS-induced THP-1 cells.

**Figure 8** The phagocytosis activity of monocytes in LPS-induced THP-1 cells is inhibited by knockdown of LINC00963.
2016). SNHG6 (HGNC: 32965), also named as U87HG, which is mapped to chromosome 8q13, has been identified as an onco-gene in various cancers, including breast cancer, gastric cancer, and colorectal cancer (Lv et al.; Xu et al., 2019; Yan et al., 2017). However, to our knowledge, no previous study has linked PAX8-AS1 and SNHG6 with sepsis. In our study, we found that PAX8-AS1 and SNHG6 may participate in sepsis by acting as ceRNAs of HDAC6 through sponging hsa-miR-181a-5p in ceRNA network.

In conclusion, a total of 290 DEmRNAs and 46 DEmiRNAs in septic patients were obtained. In addition, PAX8-AS1/SNHG6/hsa-miR-181a-5p/HDAC6, LINC00963/hsa-miR-34a-5p/UBAP2, and LINC00963/hsa-let-7b-5p/ACVR1/COX7B were identified as important interaction pairs which may involve in the process of sepsis. Importantly, a series of function experiments indicated that knockdown of LINC00963 could promote cell proliferation, reduce cytokine expression, and suppress inflammascome activation and phagocytosis in LPS-induced THP-1 cells. Hence, we speculated that knockdown of LINC00963 might be effective for the treatment of sepsis. However, there are also a few limitations in the present study. For example, sample size for RNA-sequencing was small. Only LINC00963 was validated and its underlying molecular mechanism remains unclear. Further researches with large sample size are required to perform to validate these findings.

ACKNOWLEDGMENTS
