From A to Z: Wearable technology explained

A. Godfrey, V. Hetherington, H. Shum, P. Bonato, N.H. Lovelle, S. Stuart

1. Introduction

Wearable technology (WT, or wearable computing) encapsulates a plethora of devices worn directly on or loosely attached to a person. Commonly, the latter comprises smartphones, which have become integral to the popularity and functionality of WT. Although there is a plethora of devices worn directly on or loosely attached to a person.

In short, WT can be subdivided into two categories: (i) primary, those operating independently and functioning as central connectors for other devices and/or information (e.g. wrist worn fitness tracker, smartphone) and; (ii) secondary, capturing specific actions or executing a measurement (e.g. heart rate monitor worn around the chest) off-loading to a primary wearable device for analysis. Additionally, those categories may include smart textiles where the physical properties of the material can measure or react to stimuli from the user or environment. Smart textiles currently lay beyond the scope of normal daily use as the concept of wearing electronic or uncommon tailoring materials interwoven within clothes or directly on the skin remains the vernacular of technological idealists.

Nevertheless, fuelled by miniaturisation of electronic-based components, WT has experienced an evolution since first appearing as means to take traditional desktop computing on the go. With the ability to gather and store data as well as perform complex permutations in any real-world environment it hasn’t taken WT long to enter the consumer market. Qualitative studies have seen the demise and rebirth of WT as useful aids to assist daily living. This is primarily due to the rise of third party applications (i.e. apps) which have nurtured innovation but at the expense of well-organised app development, leaving the end-user overwhelmed with choices. Indeed, the mobile computing power of smartphones is so influential that they will likely play a key role in ongoing WT innovations such as performing quick, robust and easy bioassays anywhere and at any time.

In short, WT can be subdivided into two categories: (i) primary, those operating independently and functioning as central connectors for other devices and/or information (e.g. wrist worn fitness tracker, smartphone) and; (ii) secondary, capturing specific actions or executing a measurement (e.g. heart rate monitor worn around the chest) off-loading to a primary wearable device for analysis. Additionally, those categories may include smart textiles where the physical properties of the material can measure or react to stimuli from the user or environment. Smart textiles currently lay beyond the scope of normal daily use as the concept of wearing electronic or uncommon tailoring materials interwoven within clothes or directly on the skin remains the vernacular of technological idealists.

Nevertheless, fuelled by miniaturisation of electronic-based components, WT has experienced an evolution since first appearing as means to take traditional desktop computing on the go. With the ability to gather and store data as well as perform complex permutations in any real-world environment it hasn’t taken WT long to enter the consumer market. Qualitative studies have seen the demise and rebirth of WT as useful aids to assist daily living. This is primarily due to the rise of third party applications (i.e. apps) which have nurtured innovation but at the expense of well-organised app development, leaving the end-user overwhelmed with choices. Indeed, the mobile computing power of smartphones is so influential that they will likely play a key role in ongoing WT innovations such as performing quick, robust and easy bioassays anywhere and at any time.
2. Wearables: an A–Z guide

The following details a selection of the most commonly used devices, terminologies and areas of interest. For simplicity, we present an A–Z guide (Fig. 1).

2.1. A is for algorithm

WT comprise different electronic-based sensors depending on measurement needs, e.g. electrocardiogram, blood glucose. For simplicity, sensors will generate an electrical signal when detecting physiological signs/responses, captured many times a second (high sampling frequency, SF) or every few minutes (low SF) depending on measurement needs. Subsequently, signals are stored as complex/raw time series data by acquisition electronics. Off-the-shelf commercial devices use proprietary software with embedded algorithms to download data, extract pertinent features and generate required outcomes (e.g. heart rate). Additionally, most WT facilitate access to raw data to allow the creation of bespoke algorithms via research tools (e.g. Matlab®, R) for more insightful patient assessment [5]. This aligns to trends in open-source development options, making algorithms transparent compared to black-box designs. Broadly, algorithms (within software/apps) are structured computer-based protocols to process and analyse sections of raw electronic signals/data to derive real world, meaningful outcomes. Algorithm syntax can be complex given the permutations of data interpretation needed but pseudo-code representations offer some insight to operations, like in eye tracking [6].

2.2. B is for big data

WT can continuously monitor many times a second for days or weeks. However, this will negatively affect running time between battery recharge/replacement and memory capabilities: increased data capture means reduced WT deployment time. Although WT can use large batteries or memory units, this will make WT impractical, too big and bulky to wear discretely. Thus, when deploying WT, data acquisition appreciation is required to ensure robust data collection procedures. For example; too little data and vital clues to diagnose or treat a patient may be missed; alternatively, mining/searching big data for clinically sensitive/relevant outcomes is complex. One common approach is to place WT in a low-power mode and only power up additional sensors when a possible event that is of interest has been detected [7].

2.3. C is for cloud (computing)

Most WT is now part of the Internet of Things (IoT): connectable to digital communication infrastructures, facilitating rapid data transmission and storage. The latter is big business and growing, with overwhelming future estimates of 2.3 trillion gigabytes (GB) of IoT-based data produced daily by 2020 [10], reaching an accumulation of...
847 zettabytes (ZB) by 2021 [11]. Indeed, we are on the cusp of the yottabyte (YB) era which heralds a need to consider how big data is used as large proportions remain underutilised [11]. The cloud (and clustered IT infrastructures, i.e. data centres) can overcome limitations by providing ubiquitous computerised economies of scale: the power of a super computer accessed anywhere through any device. However, cloud computing is still maturing, such as implementing optimisation methodologies like (the aptly named) fog and cloudlets to process data at network edges, i.e. on more local systems like smartphones. Hence, that topic of research is termed edge computing where real-time analytics plays a key driver to improve data efficiency [12].

2.4. D is for design

Technology-driven developments rather than co-creation driven by end-users (user centred design) led to discrepancies between project aims and outputs from the EU Ambient and Assisted Living Joint Programme [13]. Although WT stems from an evolution of computing and sensing technologies, its continued revolution relies on interactions with numerous stakeholders from all ages. Younger generations are exposed to technologies from an early age, making adoption and use instinctual. Yet, older adults remain excluded from aiding technology design and development for their generation, described as a lack of involvement to build their own future [14]. Furthermore, WT often lacks considerations for the wearer’s physical, psychological and social preferences [15] as holistic end-user preferences need consideration [16]. Contemporary frameworks exist to guide WT design ensuring a human-centred approach [16], as well as novel reflective themes which could be more broadly applied to other topics influencing WT [14].

2.5. E is for efficiency

Deploying WT for prolonged periods is difficult due to two primary WT criteria: battery life and memory capacity. Current studies aiming to gather longitudinal data may adopt a series of n-of-1 methods, repeated measurement of an individual over time (with low SF) allowing conclusions to be drawn about the individual [17]. That method of data gathering can complement traditional study designs and would help personalise health behaviour interventions to individuals [18]. Moreover, it could help carefully manage study resources, optimising personnel time and minimise costs due to reduced WT expenditure. However, studies needing to deploy WT on larger patient numbers for more data (with high SF) must deal with device logistics, e.g. rotating fully charged WT between users. Typically, battery limitations outweigh memory, as it constitutes the bulkiest component. Alternatively, energy harvesting for improved efficiency, utilises the dynamic energy (e.g. body heat, friction, movement) of the wearer to continuously (months) power wearables through smart materials has been suggested [19].

2.6. F is for fusion

Current WT inefficiencies are offset by the application of data fusion techniques from different sensors and technologies. For example, a more reliable indication of pulse rate is achievable by signal fusion from electrocardiogram and pulse oximetry. Continuous monitoring with WT is aided by gathering additional data from ubiquitous devices placed within habitual environments. Yet, coherent analysis with data gathered from other sensor types, capturing at diverse specifications with alternate algorithms, is a challenge. Data fusion techniques stemming from WT have been presented [20], detailing considerations like number of sensors to adequately provide seamless monitoring, paramount for complex conditions with multiple co-morbidities. Multi-sensor data fusion has many engineering obstacles [21], but pragmatic implementation remains equally challenging, e.g. access to commercial data; knowledge sharing between companies; uptake/integration within national/private health services.

2.7. G is for GDPR (General Data Protection Regulation)

In 2016 the EU Parliament approved GDPR to replace the Data Protection Directive 95/46/EC, aiming to empower individuals by strengthening and merging data protection as well as addressing the export of personal data outside the EU (Additional information found here). Requirements for firmer data regulations were justified by considering technology foresight and examining a range of national and political organisations influencing policy across many technologies [22]. Four factors were identified which complicate data protection and privacy that are applicable to WT:

1. It’s hard to understand what new technologies are doing and the real limits of their capabilities.
2. Technological development is not linear and disruptive breaks can occur which bring about qualitative changes in circumstances, making prediction from past technologies challenging.
3. Technology cannot be taken in isolation; it should be assessed alongside a range of other technologies to aid combination.
4. Technologies do have affordances (relational properties supporting different actions) but can be used in ways unintended by designers and developers.

A notable example of the latter was a serious security breach of wrist worn WT in the context of divulging secret information (i.e. key entries) while people accessed key-based security systems [23].

2.8. H is for hardware

Most WT may comprise the same underlying hardware, the only difference being algorithms and visualisation tools (on a smartphone/computer) that decipher and graph the data, respectively. One example is WT quantifying human movement, where inertial sensors (typically accelerometers) generate a signal when the wearer moves. Depending on where WTs are worn, sensors will generate different signal shapes requiring different algorithms to interpret data to generate specific outcomes [24]. Generally, more outcomes mean more embedded sensors or algorithm complexity creating a trade-off for length of use, influenced by: (i) battery life (to power all functionality) and; (ii) abundance of data stored.

2.9. I is for instrumented

WT value in everyday clinical practice is yet to be realised. WT is often used without healthcare professionals appreciating the extent of its capabilities but broad recommendations are provided [25]. Furthermore, WT can be a hindrance to those in working in healthcare due to cost, complexity of integration to existing technology frameworks and need to upskill. Sometimes low-tech works but realising how WT can add value is key. Recent approaches to understanding ageing phenotypes highlight the instrumented approach to measure traditional tasks like gait speed, replacing manual observations with a stopwatch. Where the latter was prone to observation variations/errors in recording(s), WT facilitates a standardised (computerised) approach to

---

\[1\] 1 ZB = 1000^7 \text{ bytes} = 10^{21} \text{ bytes} = 1,000,000,000,000,000,000,000,000 \text{ bytes} = 1000 \text{ exabytes (EB)} = 1 \text{ million petabytes (PB)} = 1 \text{ billion terabytes (TB)} = 1 \text{ trillion GB}.

\[2\] 1 YB = 1000^9 \text{ bytes} = 10^{24} \text{ bytes} = 1,000,000,000,000,000,000,000,000,000 \text{ bytes} = 1000 \text{ ZB} = 1 \text{ trillion TB}.

\[3\] Those collectively labelled generations: Z, Y (millennials) and less often, X.

gathering data in any environment, often with additional outcomes usually obtained by larger and more expensive devices in specialist settings [26,27]. Additionally, ongoing work is examining motor phenotyping individuals (e.g. Parkinson’s) and Alzheimer’s disease), where WT has gained a great deal of interest among rehabilitation and movement disorder specialists [28,29].

2.10. J is for jewellery

A recent exploration of patents suggested that a key factor for immediate WT success is a need for a clear strategic vision within healthcare [30]. The referenced study suggests that in addition to focusing on current WT norms (e.g. smartwatch) companies should invest in new subclasses (e.g. smart jewellery) where there are high potentials for growing products. Suggestions by a major telecommunications provider propose sensors beneath the skin as mainstream by 2049 to aid automated emergency responses. Current work to achieve that goal is examining mobile (false) nails accompanied by connected jewellery that will let you walk into the nail by raising your finger to your face [31]. Although that idea is visionary and stylish, current WT jewellery (Table 1) are equally so but lack focus and the “wow” factor [32] by replicating mundane outcomes: there is a need to merge style with leading research to ensure novel concepts aren’t left in the vintage collection.

2.11. K is for kits

Professional groups no longer work in isolation; there is a requirement for multidisciplinary teams to share experiences and knowledge. Therefore, the necessity to be technology literate is more profound than ever allowing diverse groups to work efficiently and effectively. For those within healthcare sciences, developer kits (DK) are presented as a means of increasing some basic technical insights to WT. Typically, software DK (SDK) are more commonly discussed (e.g. SDK6 for an iOS app) but they are quite complex and require specific expertise. Alternatively, affordable hobby-based DK are growing in popularity. Generally, DK come with simple projects for hardware and software integration as well as online help resources. Current DK allow easy upskilling and a basic appreciate of some technical WT design and development, Table 2.

2.12. L is for low cost

WT offers a one-stop-shop to monitor people in their natural living environments, potentially offering better insight compared to occasional clinical observations. A single WT can offer numerous sensing capabilities with multiple algorithms, termed collapse of functionality [33], to allow for more streamlined and efficient healthcare monitoring. Commercial competition and huge economies of scale drive the price of WT down, passing low costs to the consumer (single user or health service provider). The ability to self-monitor (e.g.) to avoid the burden of waiting rooms has led consumers (patients) yearning for convenience, simplicity, speed and immediate satisfaction. Consequently, there is increasing growth for affordable on-demand services (e.g. Uber) where health represents the second fastest growing segment [34].

2.13. M is for machine learning

Machine learning (ML, akin to computational statistics) algorithms have emerged as useful analytical methodologies, undoubtedly due to the rise of big data. Typically, the machine/computer learns from a training set of data where outcomes are mapped to specific data characteristics. That is the basic concept that differentiates ML from artificial intelligence (AI), the latter being more autonomous. ML is captured for clinical scientists in a previous tutorial including: relevant terminology; relationship to traditional biomedical statistics; application to WT clinical measurement7; and limitations [35]. ML algorithms and their application(s) are numerous, current examples include: decision trees for classifying motoric activities [36]; and neural or deep learning networks for measuring upper limb rehabilitation [37], disease state in Parkinson’s [38] and managing large amounts of time series data from a large number of input channels with a high temporal resolution (several kHz) such as electroencephalography [39]. Table 3 describes an open resource for those wishing to try some ML-based analysis.

2.14. N is for nursing

An article published before the turn of the millennium highlighted a dilemma for healthcare workers (i.e. nurses): slaves or masters of technology [41]. The article provided several guidelines (some equally as relevant today for WT) to help frontline staff carefully assess the impact of emerging technologies (Table 4). Of paramount importance

Table 1
Recent smart jewellery examples (www.smartgeekwrist.com/best-smart-jewelry).

| Name                  | Worn         | Health-based functionality                                                                 | Colour                  |
|-----------------------|--------------|-------------------------------------------------------------------------------------------|-------------------------|
| Bellabeat Leaf Urban  | Necks, wrist | Activity and sleep, Stress, Menstrual cycle                                               | Rose Gold, Silver       |
| Ringly Luxe smart ring| Fingers      | Activity tracking (steps, distance, calories burned). Mindfulness – meditation and breathing exercises | Gold/Lapis, Gold/Black Onyx |
| Fitbit Flex 2         | Wrist        | Activity (including swimming) and sleep tracking                                           | Black, Lavender, Magenta, Navy |
| Misfit Shine (with Bloom Necklace) | Wrist, neck | Activity (inc. sports) and sleep tracking                                                  | Black, Grey, Champagne and 7 more |
| Ringly Luxe smart bracelet | Wrist      | Activities (steps, distance, calories burned)                                              | Silver/Blue Lace Agate, Gold/Lapis |
| Omate Ungaro          | Finger       | None – vibration alerts for calls and texts                                                 | Gold, Silver            |
| Michael Kors access bracelet | Wrist | Activity tracker with sleep monitoring                                                    | Rose Gold/Pink, Black, Blue, Silver, Rose Gold/Grey |
| Mira wellness & activity bracelet | Wrist, clip  | Activities (steps, elevation, calories burned, distance). Motivation (gives fitness tips) | Midnight Purple         |
| Joule earring backing | Earring backing | Continuous heart rate tracking. Activity tracking and level measurement via headset | Silver                  |
| Netatmo June          | Bracelet     | UV bracelet hat’s designed to keep you safe from the sun’s harmful rays                   | Gold, charcoal, platinum |
| Moodmetric            | Ring         | Stress management (detects stress levels by measuring electrodermal activity)             | Black, grey, plum and turquoise |
| Grace                 | Wristband (bracelet) | Automated tracking and cooling device for women experiencing menopausal hot flushes   | Rose gold with grey     |

Try me – A resource to deploy some ML methodologies.

Waikato Environment for Knowledge Analysis*

A Java-based ML software that is openly available.* Contains online documentation, video tutorials and courses available through its webpage to explore how it can be used for data mining. WEKA allows users to dabble with ML algorithms on WT datasets without writing any code. Users access a selection of graphical interfaces, choosing menu and form filling options to implement ML algorithms and visualise the results. Suggested ways of using WEKA are (i) to apply a ML method to a dataset and analyse its output to learn more about the data or (ii) to use ML models to generate predictions on new instances [40].

Table 4
1999 based guidelines for wise technology integration.

1. Technology systems must be patient centred
2. Technology must be thoughtfully applied
3. Technology should have an invisible interface when possible
4. Technology should be carefully integrated
5. Nurses must avoid on overreliance on technology
6. Technology must be evaluated as a team
7. Sometimes less is best
8. Technology cannot replace humanity

for point 5 the authors note that “data are not information” and “must be interpreted before they can be considered real information”. Certainly, the role of current and future WT should enhance the role of frontline staff. Yet, future work must help frontline clinical staff understand how WT data translates to sensitive clinical information/outcomes and how validation and standardisation procedures play a key role in that process.

2.15. O is for open-source

2018 marks the 20th anniversary of the Open Source Initiative (OSI), a non-profit organisation advocating open-source software. For simplicity, (free and) open-sourced software (FOSS) will be described here as software that is freely available and applied as the users deems necessary. There is no doubting OSI and FOSS have proliferated WT research and development (R&D) with languages (e.g. Python™) and platforms (e.g. WEKA, see W) accessible to all rather than groups using bespoke software in premier institutes. Open-source (but not necessarily free) hardware examples include Arduino and Raspberry Pi, where the latter slightly differs due to its closed firmware, i.e. low-level software to control specific hardware functionality. Regardless, their low-cost and easy availability make for interesting low-cost solutions to current clinical-based WT research [42].

2.16. P is for pets

WT isn’t just for humans, it has extended its reach to our home-based pets to impact human health. Options exist for pet owners to track the activity of their furry friends in their natural surroundings where some algorithms provide insight to emotional behaviour and stress [43]. In fact, pilot work involving WT showed promise to improve communication between working (guide) dogs and their handlers [44]. Currently, the focus of WT is generally on pet health and costs associated with insurance [45]. However, WT could better inform animal-assisted interventions (AAI) where several theoretical and practical challenges remain [46]. Better understanding of animal and owner activities could aid AAI where dog ownership indicates potential health improvements due to increased ambulation [47].

2.17. Q is for quality of life

WT was recently labelled as a digital compass to navigate everyday choice, counting and controlling how “bites, sips, steps and minutes of sleep” impact health, but this can bypass individual responsibility and self-regulation [48]. Undoubtedly, WT can help users achieve healthier lifestyle goals if regulated with appropriate, expert guidance but over reliance on the fixed thresholds/scores within WT can negatively impact health. Use of wrist-worn WT with feedback mechanisms showed healthier trends in eating and exercise but users felt under pressure to reach daily targets. Almost one third felt the WT was an enemy and made them feel guilty [49]. Therefore, it is important to consider the long-term psychological as well as physiological effects of WT.

2.18. R is for reliability

WT should be validated according to an expert set of standardised validation procedures while also ensuring it remains reliable over time. WT sensors are prone to a phenomenon called drift, physical changes which results in error accumulation. Most modern WT should have recalibration strategies to account for drift, e.g. time synchronisation to network protocols. The use of a gold standard reference is often described but in truth, all equipment will slightly differ in their functionality as well as having some inherent error. Therefore, allowance must be made for some discrepancies when comparing between WT and
other devices [50]. For those that are unsure, simple bench testing of
the device against a reliable scale would help check accuracy over time. For
example, video recording and counting the steps from a pedometer with
a participant on a treadmill at different speeds. Ultimately, calibration
procedures must be conducted prior to deployment ensuring (with some confidence) WT reliability.

2.19. S is for standardisation

Technical/engineering standards allow WT to connect via known
communication protocols (e.g. Bluetooth) created by the IEC.9 IEEE10
or ISO.11 This allows WT developers to ensure their devices integrate
with other technologies. Additionally, some IEEE standards are avail-
able which relate to WT measurement, validation and data reporting.
An example includes wearable, cuff-less blood pressure measuring de-
vices detailing appropriate statistical analysis that should be taken,
ensuring confidence in reported outcomes [51]. However, researchers
generally rely on openly available resources to guide work. Contrasting
examples include the MapReduce framework for processing and gen-
erating big data or the PRISMA12 set of items in systematic reviews
and meta-analyses. Additionally, the Personal Connected Health (PCH) Al-
liance publishes the Continua Design Guidelines, an implementation
framework for authentic, end-to-end interoperability of personal con-
ected health devices and systems. Yet there is scope for standard
enhancement with open guidance for non-experts needed on how best to
(e.g.) construct algorithms, plan and conduct appropriate validation/ liability protocols as well as statistical analysis.

2.20. T is for terminology

Lack of WT standardisation is encapsulated by heterogeneity of WT
terms, with authors often interchanging phrases (e.g. measurement
term, wearable/motion sensors) or creating study specific acronyms
that can be confusing for those new to the field. This also relates to similar
WT outcomes with notable differences observed. Ideally, the field
should be adopting terminology from a predefined set of standards akin
to the adoption of clinical terminology created by healthcare specia-
lists.13 The rationale to do so ensures routine integration of information
systems, such as transforming paper into digital records and ensuring
universal interoperability among all forms of electronic data.14 This is
of utmost importance when considering (e.g.) file formats, naming
conventions or metadata where no common terminology exists al-
though interfacing through the HL7/FIHR would facilitate a useful
starting point.15

2.21. U is for ubiquitous

Data fusion methodologies could facilitate more continuous mon-
itoring with the use of ubiquitous sensing technologies, addressing
short-term limitations of WT: periodically downloading data from WT
to free memory. Ideally, (ethically valid) ubiquitous sensing would
(e.g.) relay technical information between technologies to harmonise
data streams or; facilitate WT integration as the user enters different
surroundings. With up to 10-trillion sensors connected to the internet in
the next decade [52], systems/frameworks to identify, track and local-
ise WT within all environments becomes difficult. Therefore, the uti-
isation of additional Positioning, Navigation and Timing (PNT)
infrastructures to complement current systems (e.g. GPS) as well as the
advent of the next generation of mobile connectivity16 becomes para-
mount to achieve seamless and pragmatic ubiquitous WT.

2.22. V is for validation and verification

Increased WT awareness within healthcare user’s innovative
methods to deliver modern approaches to improve patient treatment
and management. Consequently, this sector is rife with opportunities
where WT can offer efficient methodologies to gather sensitive data for
more informed diagnosis. This may hasten development but conversely
exposes users to poor WT, void of robust design with insufficient patient
or clinician engagement; pragmatic utility; validation or verification.
The creation of WT (inc. apps) and deployment within clinical settings
is a contentious topic as it is difficult to determine if devices/products
are (in vitro diagnostic) medical devices falling within the EU Medical
Device Directive (MDD) framework [53]. (Devices or algorithms used in
approved regulatory devices, e.g. CE17 marking, are subject to suitable
validation and verification procedures, often through clinical trials, to
ensure that they perform as specified on the intended population.) Yet
WT remains novel within healthcare where regulations require the
manufacturer to perform internal verification processes only (ensuring
basic compliance), often forgoing expensive and time consuming vali-
dation. No regulations exist for the robust capture and quantification of
WT outcomes including expert guidance on suitable validation or ver-
ification procedures for any physiological outcome. Healthcare profes-
sionals should be cautious if adopting WT where a lack of transparency
can conceal hidden barriers to robust patient assessment. For example,
algorythms may utilise subjective thresholds to quantify outcomes that
go unreported by the manufacturer [54].

2.23. W is for wearability

WT remains finely poised as a useful and pragmatic aid to inform
healthy living. Yet, WT rides on waves of success from the latest
mainstream gadget by a large corporation to show utility as a viable
means to monitor the user during free-living, providing round the clock
habitual data. Therefore, success is built on the fickle nature of con-
sumerism and brand loyalty rather than an ability to quantify sensitive
(clinically relevant) ageing or disease specific outcomes. Primarily,
adoption of technology remains bound to the glamorous nature of good
marketing or integration to smartphones. Many who receive or pur-
chase WT engage with it for short periods, grow uninterested and take it
off, reverting to usual clothing accessories. Others may not wear WT at
all, or feel that it makes them stand out for the wrong reasons, as some
ankle-based WT look like law-enforced tagging devices. Use of WT and
body placement has a great deal to do with social acceptability [55] and
may only become mainstream as perceptions change or devices become
smaller and directly integrated into clothing or injected beneath our
skin.

2.24. X is for X marks the spot

As previously discussed, depending on WT site(s) of attachment
during movement related tasks and outcomes required (e.g. gait and
step time) different algorithms may be used. Previous work detailed the
effect of site variation (chest, lower back, right wrist) on spatio-tem-
poral gait outcomes during clinical testing [56]. Accordingly, correct
WT placement is given careful consideration to ensure robust data
collection and accurate measurement of movement related tasks, i.e.

whether the site of attachment is best suited to capture the complete range of movement.

2.25. Y is for yourself

The power of WT lies in the ability to gather personalised data, allowing you to learn how poor lifestyle choices can influence negative trends in health (e.g. blood pressure). Typically, this is often referred to as self-monitoring, quantified-self or lifelogging. Robust data from valid and reliable WT can be used to aid medical diagnosis or treat the individual rather than relying solely on information about the collective. Data gathered by WT is unique to the wearer. Nevertheless, we are still in an age of discovery as abilities to detect and understand continuously evolve to inform ways to predict and prevent [57]. Ideally, strategies to target preventive medicine are developed from WT data gathered in the wild, where the complexities of normal daily living blur the ability of current algorithms to perform robustly. Additionally, WT data can contribute to self-care and effectively managing chronic disease exacerbations [58] by empowering a patient through WT data displays [59,60].

2.26. Z is for (generation) Z

Early exposure to technology breeds a familiarity that hastens abilities to adopt. Those exposed to technology (e.g. gaming consoles) in the home or computer literacy courses in school during adolescence may be considered early adopters and more willing to continuously use WT. In contrast, older generations may find it difficult to rationalise WT usage, simply because they never needed to: WT is a tool but to generation Z it can be a normal part of life [61]. The former must generally stay engaged through continuous instruction or novel experiences [62], whereas the latter are bombarded daily by technology. How current WT shortcomings with older generations map to generation Z in older age remain unknown or perhaps unwarranted. As the digital divide shrinks and disciplines like gerontechnology mature [62], WT will become the norm with little or no learning curves required.

3. Summary and conclusion

The disruptive nature of WT is leading a slow evolution within modern healthcare. The power of WT as a pragmatic and clinically useful technology to aid patient diagnosis, treatment and care is becoming evident. This is due to its low-cost ability to gather habitual data in a discrete manner for longitudinal periods in any environment. Integration to the cloud provides readily available big data, facilitating the application of machine learning algorithms for novel outcomes. However, stringent data governance and appropriate validation and verification standards/procedures are significantly lacking within the field, with the former growing through significant learning processes. Nevertheless, WT innovation is ripe and still within a R&D phase of its technology life cycle. The simultaneous implementation of appropriate data regulation, validation/verification frameworks, ubiquitous integration to global networks and maturing of generations will see WT realise its potential.

Contributors

A Godfrey created the concept and framework for the paper, gathered references, and contributed to each draft and formatting of the paper to fit journal requirements.

V Hetherington created the concept and framework for the paper, gathered references, and contributed to each draft and formatting of the paper to fit journal requirements.

H Shum contributed to each draft and formatting of the paper to fit journal requirements.

P Bonato contributed to each draft and formatting of the paper to fit journal requirements.

NH Lovell gathered references, and contributed to each draft and formatting of the paper to fit journal requirements.

S Stuart created the concept and framework for the paper, gathered references, and contributed to each draft and formatting of the paper to fit journal requirements.

Conflict of interest

The authors declare that they have no conflict of interest.

Funding

This project was supported in part by the Engineering and Physical Sciences Research Council (EPSRC, reference: EP/M002632/1) and the Royal Society (reference: IE160609).

Provenance and peer review

Peer review was directed by Margaret Rees independently of Alan Godfrey (one of the authors and Guest Editor of the Maturitas special issue Modern Medicine for Healthy Ageing), who was blinded to the process.
