Chapter

Bluetooth Low Energy Applications in MATLAB

Septimiu Mischie

Abstract

This chapter presents Bluetooth Low Energy (BLE) applications in MATLAB. Through these applications we acquire measurement data from BLE compatible sensors to PC. The sensors are CC2541 Keyfob and CC2650 Sensor Tag. The first one contains an accelerometer and a temperature sensor while the second one contains more sensors, but inertial sensors and magnetometer are invoked. The PC should be equipped with a general USB BLE adapter. The most important steps for implementing a BLE application are presented: scanning, connecting, configuring and data reading. Following this, more detailed applications are presented: a wireless sensor network for temperature measurement with three Keyfob-based nodes, an application that displays in real time accelerometer data and a heading computed method using either the gyroscope or the magnetometer of CC2650 Sensor Tag. The most important MATLAB elements that are used to implement these applications are different types of variables such as structure, table and object, methods to implement endless loops and real-time display of acquired data and using quaternions to handle 3D orientation of a device.

Keywords: MATLAB, Bluetooth low energy, temperature sensors, movement sensors, callback function, quaternion, 3D orientation

1. Introduction

MATLAB represents a programming language that is used for designing, simulating and testing of different technical systems [1]. This chapter provides examples of Bluetooth low energy (BLE) applications implemented in MATLAB. In this section, the main aspects regarding developing a BLE MATLAB application are presented. First of all, basics about BLE technology are presented [2-5]. BLE means exchange data between two or more devices by radio waves over short distances. Mainly, a BLE device can be scanner or advertiser. The advertiser signals its presence by sending its name and address. The scanner finds advertiser devices and can connect to one or more of them. Then the advertiser becomes a server and can send data to the scanner which is now a client. According to BLE architecture, the server can offer services to the client. Some examples of services are battery service, accelerometer service and heart rate measurements. Each service contains more characteristics. The most important attribute of a characteristic is its value, which in general represents sensor data. In addition, a characteristic has one or more of the following properties: read, write and notify.
Starting with 2019b release, MATLAB has introduced a set of functions that allow a simple implementation of BLE application [6]. The minimum setup involves a laptop having an embedded BLE adaptor or a desktop having an USB BLE adapter and some BLE compatible devices.

Scanning for BLE devices can be done using `blelist` function. Connecting to one device can then be done by `ble()` function, as in the examples of Figure 1.

It can be seen that three BLE devices have been discovered. The connection with Keyfobde99 is achieved, and b1 is a `ble` object having 5 fields, the last two being Services and Characteristics so in previous paragraph was presented. Then, in order to get data from a BLE device, the characteristics have to be accessed. Figure 2 presents the last part of the Characteristics variable.

A characteristic can be accessed either by service name and characteristic name or by service universal unique identifier (UUID) and characteristic (UUID) [6]. According to the information from Figure 2 it can be seen that only the second option can be used because there are more Custom services or characteristics.

```
>> list-blelist('timeout',15)

```

Figure 2.
A part of services and characteristics of a `ble` variable.
Furthermore, there is no information about the functionalities of these services or characteristics. Therefore, to start the application, some information is necessary that can be obtained using another application such as BLE Device Monitor [7] or just Wikipedia [8]. Thus, Table 1 presents service name and characteristic name among to UUID for a part of the positions of Figure 2.

In order to access a characteristic, the characteristic () function can be used, as in Figure 3. Then, after defining x variable, the returned value can be read by function read(x).

Another powerful features is DataAvailableFcn than can be assigned to a characteristics that has the Notify attribute. This can be done as in Figure 4. When a new data is available, this callback function is called.

| Service Name     | UUID   | Characteristic Name          | UUID   |
|------------------|--------|------------------------------|--------|
| Accelerom. service | FFA0   | Accelerometer enable         | FFA1   |

Figure 4. Create the callback function.
Each of the following sections contains an introduction where the basic function of the program is presented, which is then followed by the program and the results, mainly in graphical form.

2. BLE network sensors for temperature monitoring

This section presents a MATLAB application that uses three temperature sensors. CC2541 Keyfob [9] is a BLE compatible device that contains an accelerometer. Among its basic function, the accelerometer contains an 8-bit temperature sensor. To access the temperature sensor the accelerometer must be enabled first and then the temperature characteristic can be accessed according to Table 1. The period of reading temperature is 3 sec. according to the author publication [10].

At the beginning of the program a general scanning is executed and if none of the desired sensors are discovered the application is stopped through a suitable message on the screen. To do this, accessing the elements of a variable of table type, list, is performed.

Then, depending on the discovered number of sensors, which can be from one to any number (three in this application) the application gets temperature from them and displays it on a graphic. For this purpose, two structures, s_enable and s_x, having a variable number of fields have been created. Number of fields will be equal with the discovered number of sensors. The structure s_x is used to assign a callback function for each discovered sensor, too. Furthermore, the number of matrix of small axes which are generated by subplot function is equal with the number of discovered sensors.

The structure of the program is presented below.

```matlab
%%%%%%Measure the temperature by one, two or three
%%%%%Key-fob devices

clear; close all;

N=20;
V_temp1=zeros(1,N);V_temp2=zeros(1,N);V_temp3=zeros(1,N);
V_time1=d(1:N,1);V_time2=d(1:N,1);V_time3=d(1:N,1);
list=blelist; %scan
Nr=length(list);
Ng=Nr-1; % Number of Keyfob devices
```

MATLAB
disp(['Number of Keyfob devices: ' num2str(Ng)])
if Ng==0
disp('No devices')
return
end
s_enable=struct; %initialize the structure
tab='abcdef'; %the fields of the structure
for i=1:Ng
s_enable.(tab(i))=characteristic(b(i),"FFA0","FFA1");
write( s_enable.(tab(i)),1);
end
s_x=struct; %initialize the structure
for i=1:Ng
s_x.(tab(i))=characteristic(b(i),"FFA0","FFA7");
s_x.(tab(i)).DataAvailableFcn = eval(['@displayCharacteristicData_temp' num2str(i)]);
end
h=figure(1);
while (ishandle(h))
for i=1:Ng
var =eval(['V_temp' num2str(i)]);
timp =eval(['V_time' num2str(i)]);
subplot(Ng,1,i);plot(timp,var,'*');grid;title(['sensor' num2str(i)]);ylim([0 30])
xlabel('time')
ylabel('temperature, C')
drawnow;
end
pause(3)
end
clear b
%One of the three callback functions:
function displayCharacteristicData_temp1(src,evt)
global V_temp1
global V_time1

![Figure 5.](image)
The temperatures from the three sensors.
global N
[temp1] = read(src,'oldest');
time1=datetime(datestr(now,'HH:MM:SS.FFF'));
%update the last N=20 samples of temperature and time
V_temp1(1:N-1)=V_temp1(2:N);
V_temp1(N)=temp1;
V_time1(1:N-1)=V_time1(2:N);
V_time1(N)=time1;
end

The program runs in an endless loop and displays the last 20 values of the three temperatures in a MATLAB figure as in Figure 5. To stop the program, simply close the figure. In addition, the current date and time is displayed on the figure. One of the CC2541 Keyfob was on the outside sill of the window and therefore the resulting temperature was about 5 degree Celsius.

3. Using the accelerometer of CC2541Keyfob

This section presents a MATLAB application that accesses the accelerometer of the CC2541 Keyfob to read the 8-bit accelerations corresponding to the three axes. The program is similar to that of the previous section. There are also three callback functions, one for each axes. The period of reading data is set to 100 ms.

%Display in real-time the last samples of three accelerations
%of each axis

clear all; close all;
b=ble("84DD20C50B29"); %BLE connection with 84DD20C50B29
enable=characteristic(b,"FFA0","FFA1")
write(enable,1) %enable accelerometer
x=characteristic(b,"FFA0","FFA3")
y=characteristic(b,"FFA0","FFA4")
z=characteristic(b,"FFA0","FFA5")
per=characteristic(b,"FFA0","FFA6")
read_per=read(per);
write(per,10); %establish the reading period to 10*10ms
read_per1=read(per);
global vector_x;global vector_y;global vector_z
N=200;
vector_x=zeros(1,N);vector_y=zeros(1,N);vector_z=zeros(1,N);
axa =1:N;
x.DataAvailableFcn = @displayCharacteristicData_x; %functii callback,
they are %executed when sensor data are available
y.DataAvailableFcn = @displayCharacteristicData_y;
z.DataAvailableFcn = @displayCharacteristicData_z;
h=figure(1); %create the figure
while(ishandle(h)) %while the figure does exist data is displayed
plot(axa,vector_x*19.62/128,axa,vector_y*19.62/128,axa,vector_z*19.62/128);grid;legend('ax','ay','az')
ylabel('accel., m/s2')
xlabel('The most recent samples')
drawnow;
clear b %clear the variable that represents the BLE connection or disconnect
%One of the three callback functions:
function displayCharacteristicData_x(src,evt)
global vector_x
global N
[data,timestamp] = read(src,'oldest');
fprintf('Time1 %s
', datestr(now,'HH:MM:SS.FFF'))
if data>128
    data=data-256;
end
%update the last N=200 samples of acceleration
vector_x(1:N-1)=vector_x(2:N);
vector_x(N)=data;
end
The program runs in an endless loop and displays the last N=200 samples of each
the three axes. Figure 6 presents a screenshot during the running of the program.
During this time CC2541 Keyfob was moved such as one of the three axes was on
the direction of gravitational force. Thus, most of the time one of the three axes has
the absolute value close to g=9.81 m/s² while the other two are close to zero.

4. Using the movement sensor of CC2650 Sensor Tag

This section presents a MATLAB application that accesses the movement sensor
of the device called CC2650 Sensor Tag. This movement sensor contains an accel-
erometer, a gyroscope and a magnetometer. If the accelerometer of the CC2541
Keyfob which was presented in the third section generates 8-bit data, all of the three
sensors of CC2650 Sensor Tag generates 16-bit data.

The gyroscope is a three axis sensor that measures the angular rate, \( \omega(t) \). By
integrating the angular rate, the angular position \( \alpha(t) \) is obtained as

\[
\alpha(t) = \int \omega(t)dt
\]

Thus, Eq. (1) can be implemented by trapezoidal method by using samples of
\( \omega(t) \) by
\[ \alpha(t) = \alpha(t-1) + \frac{\omega(t) - \omega(t-1)}{2} dt \]  

where \( dt \) is reciprocal of sample rate.

This angle is considered in comparison with the initial position of the gyroscope which is unknown. Using the integration, it generates an error because the gyroscope has an offset. That means its output is different to zero when the gyroscope is still. Thus, by integration it follows that the angle is changed. Therefore this offset must be removed [11].

The magnetometer measures the magnetic field. Thus, if there are no other fields, it measures the magnetic field of the earth. When the magnetometer is placed horizontally, it can measure the angle from the north, \( h \), by

\[ h = \arctan \frac{m_y}{m_x} \]  

where \( m_x \) and \( m_y \) are its readings. Thus, both gyroscope and magnetometer can measure the same angle but the magnetometer has a reference which is the north. For this reason this angle is also called heading. Similar to the gyroscope, the magnetometer has a drawback too. Thus, its reading must be corrected by a process called calibration [12]. Basically, this implies a rotation of 360 degrees around its z axis in both senses followed by computation of calibrated data \( m_{x_{ cal}} \) and \( m_{y_{ cal}} \),

\[ m_{x_{ cal}} = X_g \cdot m_x - X_{off} \]  

and

\[ m_{y_{ cal}} = Y_g \cdot m_y - Y_{off} \]  

where

\[ X_g = \max \left\{ \frac{m_{x \text{ max}} - m_{x \text{ min}}}{m_{x \text{ max}} - m_{x \text{ min}}} \right\} \]  

and

\[ X_{off} = X_g \left( \frac{m_{x \text{ max}} + m_{x \text{ min}}}{2} \right) \]  

while \( Y_g \) and \( Y_{off} \) have similar expressions. Also the magnetometer is very sensitive to the magnetic perturbations that can be generated by other materials from its proximity.

Regarding BLE, CC2650 Sensor Tag offers more services. The service that allows accessing the accelerometer, the gyroscope and the magnetometer has three characteristics, as shown in Table 2, where also the UUID can be seen. The first one is

| Service Name    | UUID     | Char Name   | UUID     |
|-----------------|----------|-------------|----------|
| Movement        | F000AA80 | Data        | F000AA81 |
|                 |          | Configure sensors | F000AA82 |
|                 |          | Period      | F000AA83 |

Table 2.

UUID for the movement service and its characteristics.
used to read data. The second one is used to enable the sensors. Each axis of the
gyroscope and accelerometer can individually be enabled while the magnetometer
can be enabled only for all axes. The third characteristic allows to establish the
period of data reading. The data is presented as an 18 bytes string, where each
sensor has a field of 6 bytes, two bytes for each axis, in the order: gyroscope,
accelerometer and magnetometer. Actually UUID contain more digits but only the
different part is presented in Table 2 [8].

Because in this case the MATLAB programs are much longer than previous ones
only some parts of the achieved programs are presented. Mainly, such a program
has three parts:

- the first part when the sensor is still for a time while gyroscope data are
gathered to compensate its offset; generally in this part 200 samples are
acquired;
- the second part when the sensor is rotated with 360 degrees in both senses
around z axis while the magnetometer data are gathered to compute the
calibration; in this part also 200 samples are acquired;
- the last part has an indefinite duration when the sensor is moved while real-
time data are displayed on the different figures.

Two programs are achieved, depending of the content of the last part. In this
case there is a script and only a callback function. The period of data reading is
200 ms.

The first program computes and displays basic results from gyroscope and mag-
netometer.
Mainly it computes:

\[
\text{om} = [\text{om}_x, \text{om}_y, \text{om}_z]; \quad \text{A} = [\text{a}_x, \text{a}_y, \text{a}_z]; \quad \text{M} = [\text{m}_x, \text{m}_y, \text{m}_z];
\]

\[
\text{ang}_z_g \quad \text{the angular position (angle) around z axis, by gyroscope}
\]

\[
\text{ang}_z_m \quad \text{the angular position (angle) around z axis, by magnetometer}
\]

All the time the last N=200 samples of these measurements are available.
A part of the script is presented in the following.

ang_z_m=180/pi*atan2(AA,BB) %the magnetometer-based heading %angle
end
end %if i>200

By running the previous program, the last 200 samples of some of the measurements obtained from the gyroscope and magnetometer are displayed in real-time.

Thus, the two waveforms of the top of Figure 7 are achieved using the gyroscope while the other two from the bottom part are achieved using the magnetometer. In each case the heading is computed. The gyroscope-based angle around z axis or heading is computed using the angular rate around the z axis, see the second waveform. The heading computed by the magnetometer presented in the third waveform is based on its x and y reading which are presented in the last waveform. It can be seen that the two waveforms that represent the heading have the same variation, except at
the start. Thus the gyroscope-based heading starts from zero while magnetometer-based heading starts from about 60 degrees because it indicates the north.

By using the movement sensors, 3D orientation of a device can be computed [13–17]. This can be represented in three ways: quaternion, Direction Cosine Matrix (DCM) and Euler angles. The last representation means the rotational angles around the three axes, called pitch, roll and yaw but has a disadvantage because can reach in a singularity state. DCM does not have a singularity state but needs 3x3 elements. Thus the best representation is quaternion which represents a complex number having four components [13],

$$q = \left[ \cos \frac{\alpha}{2}, e_x \sin \frac{\alpha}{2}, e_y \sin \frac{\alpha}{2}, e_z \sin \frac{\alpha}{2} \right]$$

(8)

where $\alpha$ is the rotation angle and $e$ represents the rotation axis.

Using the accelerometer allows only computing pitch and roll angles because a rotation around z axis does not change any of the three outputs. Thus the four elements of the quaternion, denoted $q_{acc}$ can be computed by [13]

$$q_{acc} = \begin{cases} \left[ \frac{a_x}{\sqrt{2(a_z+1)}}, \frac{a_y}{\sqrt{2(a_z+1)}}, 0 \right], & a_z \geq 0 \\ -\frac{a_y}{\sqrt{2(1-a_z)}}, \frac{a_x}{\sqrt{2(1-a_z)}}, 0 \right], & a_z < 0 \end{cases}$$

(9)

Eq. (9) can be very easily implemented in MATLAB and then the quaternion can be generated by the function quaternion(). However, in order to compute the third angle (yaw) the magnetometer or gyroscope readings are necessary and more difficult equations are generated [13]. Thus, a better solution is using the functions from Sensor Fusion and Tracking Toolbox of MATLAB [18] that allows estimation of 3D orientation. The function imufilter() uses only accelerometer and gyroscope

Figure 7. Some measurements obtained from gyroscope (the two waveforms at the top) and magnetometer (the two waveforms at the bottom).
while the function `complementaryFilter()` uses all the three sensors. Thus the
**Figure 8** presents in the top panel the angles obtained by MATLAB implementation
of Eq. (9) while in the bottom panel are presented the results obtained using the
`imufilter()` function. It can be seen that the waveforms are very similar and also the
angle around z axis is zero for the first or close to zero for the second as expected.

Both `imufilter()` and `complementaryFilter()` return the result as an object. Then
the object can be called as a function having the sensor measurements as arguments
and returns a quaternion. If this quaternion becomes the argument of the `viewer()`
function [16] it follows the display of a cube that moves in real-time that imitates
the moving of the CC2650 Sensor Tag, as in **Figure 9**. However, two files,
HelperOrientationViewer.m and HelperBox.m, must be in the current folder in order to use the function `viewer()` [18].

On the other hand, using the function `eulerd()`, the quaternion form can be converted in pitch, roll and yaw angles (Euler angles) that can be represented as waveforms. This method was used to obtain the results in Figure 8. Now Figure 10 presents the three angles computed using `imufilter()`, in the top part and `complementaryFilter()`, in the bottom part. It can be seen that the angles have the same variation except that the heading around the z axis starts with zero at the top and by about 80 degrees in the bottom. This is because the `complementaryFilter()` uses the magnetometer and thus indicates the angle with respect to the north.

The program that implements these facilities is very similar to the previous one. In the following sections, only the new elements are presented.

First the new elements of the script are presented.

```matlab
viewer = HelperOrientationViewer;
SRate=1/T;
ifilt_imu = imufilter('SampleRate', SRate);
ifilt_com = complementaryFilter('SampleRate', SRate);
h=figure(1);
while(ishandle(h))
    plot(v_om');grid;legend('x','y','z') %%display the gyroscope readings
drawnow;
    if i>200
        viewer(qahrs_imu); %imu quaternions are used to move the cube
    end
end
```

Then it follows the new elements of the callback function.
qahrs_imu = ifilt_imu(A, om*pi/180);  \% for imufilter
qahrs_com = ifilt_com(A, om*pi/180, M); \% for complementaryFilter
eulerAnglesDegrees_imu = eulerd(qahrs_imu, 'ZYX', 'frame')
eulerAnglesDegrees_com = eulerd(qahrs_com, 'ZYX', 'frame')

5. Conclusions

The main MATLAB contributions of this chapter are:

• using the new introduced MATLAB functions to access BLE devices and to implement a BLE sensors network

• using the table type MATLAB to check if the desired sensors are among the discovered BLE devices

• using the structure type MATLAB having a variable number of fields to handle the discovered number of BLE devices

• retaining and updating the most recent samples of different measurements corresponding to BLE sensors and display them in real-time

• using the quaternions to handle the 3D orientation of an object

• using the new introduced MATLAB functions from Sensor Fusion and Tracking Toolbox to determine the parameters that describes 3D orientation

• displaying the cube that imitates in real-time the moving of CC2650 Sensor Tag

• as a future work, the MATLAB can be used to estimate the position of an object along with 3D orientation; in this way the tracking of an object can be completed.
