Abstract

An elliptical invisible cloak is proposed using a coordinate transformation in the elliptical-cylindrical coordinate system, which crushes the cloaked object to a line segment instead of a point. The elliptical cloak is reduced to a nearly-circular cloak if the elliptical focus becomes very small. The advantage of the proposed invisibility cloak is that none of the parameters is singular and the changing range of all parameters is relatively small.

Key words: Metamaterial, invisibility cloak, optical transformation.

Great attention has been paid to the electromagnetic (EM) cloaks due to the exciting property of invisibility [1-15]. The coordinate transformation method to control the EM fields was reported in Ref. [1]. The cloaking principle was experimentally demonstrated using reduced constitutive parameters in the microwave regime [2]. Many further theoretical and numerical studies have been devoted in the past two years [3-11]. A big problem in the full-parameter cloak is that some parameter components exist singularity on the inner boundary of the cloak, which makes the full cloak difficult to achieve even using metamaterials [2]. Recently, the elliptical cloaks have been designed and investigated in different coordinate systems [12-14]. However, the cloak parameters are fully anisotropic and some components still have singular points on the inner boundary. In principle, the above circular and elliptical cloaks try to crush the cloaked objects to a point, which results in the singular parameters.

In view of the difficulty to realize the full-parameter cloak and the imperfection of reduced-parameter cloak, a recently published theory has suggested a carpet cloak, which can hide any objects under a metamaterial carpet [15]. Different from the completely invisible cloak, the carpet cloak crushes the hidden object to a conducting sheet. The great advantage of the carpet cloak is that it does not require singular values for the material parameters. However, the carpet cloak can only hide objects placed under a conducting plane, and cannot hide objects in free space.

In this work, we propose an elliptical invisible cloak using the coordinate transformation in the classical elliptical-cylindrical coordinate system. Instead of shrinking the cloaked object to a point, the proposed cloak crushes the object to a line segment, which avoids any singularities in the constitutive parameters. Closed-form formulations are derived for both permittivity and permeability tensors. If the focus of the ellipse is very small, the elliptical cloak approaches a circular cloak. The advantage of the proposed invisibility cloak is that none of the parameters is singular and the changing range of all parameters is relatively small.

We consider the elliptical-cylindrical cloak in two dimensions. Due to the elliptical shape of the cloak, we construct the coordinate transformation in the classical elliptically-cylindrical coordinate
system \((\xi, \eta, z)\), whose relationship to the Cartesian coordinates \((x, y, z)\) is written as

\[
x = p \cosh \xi \cos \eta, \quad y = p \sinh \xi \sin \eta, \quad z = z,
\]

in which \(2p\) is the focus of the ellipse, as shown in Fig. 1. In the elliptical cylindrical coordinate system, if we assume \(p\) to be constant, then isolines for \(\xi\) can be a series of elliptical cylindrical shells with the same focus value. Then a spatial transformation from the elliptical region \(\xi \in [0, \xi_2]\) to the annular region \(\xi' \in [\xi_1, \xi_2]\) can be represented mathematically as

\[
\xi' = \frac{\xi_2 - \xi_1}{\xi_2} \xi + \xi_1, \quad \eta' = \eta, \quad z' = z,
\]

where \(\xi_1\) and \(\xi_2\) are coordinate parameters of the inner and outer boundaries of the elliptical cloak. Let \(a_1\) and \(a_2\) denote the lengths of major axes for inner and outer shells of the cloak.

The nonlinear relationship between coordinate parameters and the lengths of major axis can be expressed as

\[
\xi_i = \ln \left(\frac{a_i}{p} + \sqrt{\left(\frac{a_i}{p}\right)^2 - 1}\right), \quad i = 1, 2.
\]

We remark that the inner and outer ellipses are of the same focus value \(2p\). Hence the inner boundary will be crushed to the line segment \(2p\) using the coordinate transformation.

Similar to the procedure stated in Ref. [1], one can deduce the parameter tensors of the elliptical cloak. The relative permittivity and permeability tensors are expressed as

\[
\varepsilon'_{\xi'} = \mu'_{\xi'} = \frac{\xi_2 - \xi_1}{\xi_2},
\]

\[
\varepsilon'_{\eta'} = \mu'_{\eta'} = \frac{\xi_2}{\xi_2 - \xi_1},
\]

\[
\varepsilon'_{z'} = \mu'_{z'} = \frac{\xi_2}{\xi_2 - \xi_1} \frac{\cosh^2 \beta - \cos^2 \eta'}{\cosh^2 \xi' - \cos^2 \eta'},
\]

in which \(\beta = \xi_2(\xi' - \xi_1)/(\xi_2 - \xi_1), \quad \xi_1 \leq \xi' \leq \xi_2, \quad 0 \leq \eta' \leq 2\pi\).

Eqs. (3)-(5) provide full design parameters for the elliptical cloak in the classical elliptically-cylindrical coordinates. Clearly, the cloak is composed of inhomogeneous and uniaxially anisotropic metamaterials. For circularly cylindrical cloaks with full parameters, singular material parameters are distributed on the inner boundary [4-11], which are difficult to realize in the actual applications [2]. For elliptical cloaks which shrink the cloaked objects to a point, singular values still exist on the inner boundary of the cloaks [12-14]. The material parameters for the proposed elliptical-cylindrical
cloak which crushes the cloaked object to the line segment $2p$, however, have no singularity. This makes it possible to realize the full-parameter cloak using metamaterials.

In order to validate the elliptical cloak with the designed parameters, we make full-wave simulations based on the method of finite elements. Either TE-polarized or TM-polarized time-harmonic incident plane waves can be used. In the case of TE polarization, only $\mu_\xi$, $\mu_\eta$, and $\varepsilon_z$ components of the material parameters are required for the simulations; in the case of TM polarization, however, we only need $\varepsilon_\xi$, $\varepsilon_\eta$, and $\mu_z$ components. In this work, we only consider the TM case for space reason. The working frequency is chosen as 9 GHz.

The example we considered is a perfectly electrical conducting (PEC) cylinder covered by the elliptical cloak, in which the lengths of major axes for inner and outer ellipses are 0.025 m and 0.05 m, respectively, and half of the focus length is $p = 0.015$ m. We show that the magnetic fields are smoothly excluded from the interior region with the minimal scattering in any directions when the incident direction of plane waves is parallel to the long axis of the ellipse. When the incident waves are perpendicular to the long axis, however, a big scattering outside the cloaking region is observed. The physical reason for the incident-angle dependence is that the cloaked object is crushed to the line segment $2p$, instead of a point. In the first case, the incident direction is parallel to the line segment, which produces the minimum scattering; in the second case, the incident direction is vertical to the line segment, which produces the maximum scattering.

When the focus length $2p$ of the elliptical cloak approach zero, however, the line segment $2p$ would be shrink to a point. As a result, the elliptical cloak would approach a circular cloak, and the cloaking effect would become much better. Nevertheless, $p$ cannot be zero due to the elliptical coordinate transformation (1). Hence we select $p$ as a small value.

When $p$ is chosen as a small value, the elliptical cloak is nearly a circular cloak with outer radius $R_2$ and inner radius $R_1$. In such a case, $\varepsilon_\xi$ becomes $\varepsilon_r$ and $\varepsilon_\eta$ becomes $\varepsilon_\phi$, indicating the radian and angular components of the permittivity. In order to compare with the ordinary circular cloak [4-11], in the following simulations, we choose the shape of cloak as an exact circle while
the material parameters are given by:

\[
\varepsilon'_r = \mu'_r = k,  
\varepsilon'_\phi = \mu'_\phi = \frac{1}{k},  
\varepsilon'_z = \mu'_z = \frac{\cosh^2 \beta}{k \cosh^2 \xi},
\]

in which \(k = (\xi_2 - \xi_1)/\xi_2, \beta = (\xi - \xi_1)/k, \xi = \ln \left(\frac{r/p + \sqrt{(r/p)^2 - 1}}{r/p + \sqrt{(r/p)^2 - 1}}\right), \xi_i = \ln \left(\frac{R_i/p + \sqrt{(R_i/p)^2 - 1}}{R_i/p + \sqrt{(R_i/p)^2 - 1}}\right), i = 1, 2.\)

The full-wave simulation result for a circular TM cloak with \(p = 0.001 \text{ m}\) is illustrated in Fig. 2(a). We observe that the phase fronts are bent smoothly around the PEC object inside the cloak, and the fields are smoothly excluded from the interior region with the tiny scattering. Similar phenomena are observed for other small values of \(p\), for example, \(p = 0.003 \text{ m}\) and \(0.005 \text{ m}\) (not shown).

All material parameters for above circular cloaks have relatively small ranges. Figure 2(b) illustrates the parameter distributions inside the TM cloaks when \(p = 0.001 \text{ m}, 0.003 \text{ m}, \text{ and } 0.005 \text{ m}\). Obviously, for each \(p\), \(\varepsilon_r\) and \(\varepsilon_\phi\) are constants, and \(\mu_z\) ranges from 0 to a small constant, all of which can be realized using metamaterials. From Fig. 2(a), we clearly observe that the proposed cloak with smaller \(p\) can achieve better cloaking performance, because the cloaked object is crushed nearly to a point, which results in tiny scattered fields.

In the earlier example, the material parameters are gradiently distributed in the circular region, which are difficult to implement in real experiments. In order to design a practical cloak, we consider a layered homogeneous circular cloak which is divided into 8 layers. When we choose \(p = 0.001 \text{ m}\), the permittivity components in all layers are constants: \(\varepsilon_r = 0.151\) and \(\varepsilon_\phi = 6.641\), while the permeability component \(\mu_z\) is given by \(0.025, 0.193, 0.466, 1.063, 1.90, 2.756, 3.95,\) and \(5.60\) in all layers. We remark that we choose different thicknesses for the 8 layers due to the nonlinear distribution of the permeability.

Figure 3(a) illustrates the simulation results of the layered cloak. We clearly observe a good performance of the invisible cloaking although we applied the designed parameters for a nearly-circular cloak to a layered circular cloak. From Fig. 3(a), the cloak forces the incoming plane waves
to propagate around the inner cloaked region, and such waves return to their original propagation
directions without distorting the waves outside the cloak.

In real applications, artificial metamaterials are always lossy. Hence it is important to study the
lossy effect of cloak on the invisible property. Figure 3(b) shows the magnetic-field distributions
for the cloak with electric and magnetic-loss tangents of 0.03. From this figure, although the
inhomogeneous cloak has been partitioned into eight homogeneous layers and both the permittivity
and permeability have a relatively large loss, we still observe good overall invisibility property except
in the forward-scattering direction.

The present cloak can be realized experimentally by designing proper metamaterial structures.
To achieve the constant $\varepsilon_r$, we can use the electric resonant structures which align in the $r$-$z$ plane.
To realize the varying $\mu_z$, we can use the split-ring resonators which align in the $r$-$\phi$ plane. The
constant $\varepsilon_\phi = 6.641$ can be obtained using non-resonant structures like wires or I-shapes. It will
be a hard work to optimize the overall design to make a compact layout of cylindrical cloak.

Compared with the full-parameter cloak [1], the advantage of the proposed invisibility cloak
is that none of the parameters is singular and the changing range of all parameters is relatively
small. To compare with the reduced-parameter cloak [2], we compute the scattering width for the
PEC target only and the PEC target covered by the reduced cloak [2], the proposed layered cloak
without loss, and the layered cloak with electric and magnetic-loss tangents of 0.03, as shown in
Fig. 3(c). Clearly, the proposed cloak has a much better overall performance of invisibility.
