Abstract

Background: Granulosa cells (GCs) represent a major endocrine compartment of the ovary producing sex steroid hormones. Recently, we identified in human GCs a Ca2+-activated K+ channel (KCa) of big conductance (BKCa), which is involved in steroidogenesis. This channel is activated by intraovarian signalling molecules (e.g. acetylcholine) via raised intracellular Ca2+ levels. In this study, we aimed at characterizing 1. expression and functions of KCa channels (including BKCa beta-subunits), and 2. biophysical properties of BKCa channels.

Methods: GCs were obtained from in vitro-fertilization patients and cultured. Expression of mRNA was determined by standard RT-PCR and protein expression in human ovarian slices was detected by immunohistochemistry. Progesterone production was measured in cell culture supernatants using ELISAs. Single channels were recorded in the inside-out configuration of the patch-clamp technique.

Results: We identified two KCa types in human GCs, the intermediate- (IK) and the small-conductance KCa (SK). Their functionality was concluded from attenuation of human chorionic gonadotropin-stimulated progesterone production by KCa blockers (TRAM-34, apamin). Functional IK channels were also demonstrated by electrophysiological recording of single KCa channels with distinctive features. Both, IK and BKCa channels were found to be simultaneously active in individual GCs. In agreement with functional data, we identified mRNAs encoding IK, SK1, SK2 and SK3 in human GCs and proteins of IK and SK2 in corresponding human ovarian cells. Molecular characterization of the BKCa channel revealed the presence of mRNAs encoding several BKCa beta-subunits (beta2, beta3, beta4) in human GCs. The multitude of beta-subunits detected might contribute to variations in Ca2+ dependence of individual BKCa channels which we observed in electrophysiological recordings.

Conclusion: Functional and molecular studies indicate the presence of active IK and SK channels in human GCs. Considering the already described BKCa, they express all three KCa types known. We suggest that the plurality and co-expression of different KCa channels and BKCa beta-subunits might allow differentiated responses to Ca2+ signals over a wide range caused by various intraovarian signalling molecules (e.g. acetylcholine, ATP, dopamine). The knowledge of ovarian KCa channel properties and functions should help to understand the link between endocrine and paracrine/autocrine control in the human ovary.

Background

Ion channels of ovarian granulosa cells (GCs) have been identified and functionally characterized in only a few species (human, swine, chicken) ([1-3] and references in [4]). In human and porcine GCs, several channel types are involved in the physiologically important process of progesterone production [4-7]. A KCa channel of large (big) conductance (BKCa) in human GCs has a part in endocrine-regulated progesterone production [8]. Blocking of BKCa channels results in reduction of human chorionic gonadotropin (hCG)-induced progesterone production, but does not affect basal steroidogenesis.

Moreover, BKCa channels in human GCs were shown to be opened by cholinergic and oxytocinergic stimulation entailing transient membrane hyperpolarisation [8]. Acetylcholine (ACh) is produced by and also acts upon human GCs. In the human ovary, the non-neuronal cholinergic system affects several physiological functions, e.g. cell proliferation, gene transcription, and intercellular communication via gap junctions [9]. It represents just one of the local signaling systems which have been identified in recent years to complement endocrine (FSH, LH/hCG) and neuronal control of ovarian functions via autocrine/paracrine pathways. Besides ACh, other local intraovarian signaling molecules are peptide hormones (e.g. oxytocin, relaxin), catecholamines (e.g. norepinephrine, dopamine), ATP, prostaglandins, GABA and histamine. Many of these compounds (e.g. ACh, oxytocin, relaxin) exert their actions upon GCs via alteration of intracellular Ca2+ levels [Ca2+]i [8-12]. In human GCs, ACh and its agonist carbachol activate muscarinic receptors (e.g. M1) and increase [Ca2+]i via Ca2+- and voltage-dependence of the BKCa channel was determined in electrophysiological single-channel recordings. As BKCa channel characteristics are affected by the type(s) of accessory β subunits present, we studied their expression in human GCs as well. There are four potential types known (β1, β2, β3, and β4), which interact with the α subunit and regulate BKCa channel function regarding impact of Ca2+ and voltage [25-29]. They represent also binding sites for toxins and drugs as well as phosphorylation sites [26,27,30-32].

Methods

Human GC preparation and culture

Human GCs were isolated from follicular aspirates of women undergoing IVF and cultured in DMEM/F12 (10% FCS; Sigma-Aldrich, Munich, Germany) under a humidified atmosphere at 37°C/5% CO2 [33]. Use of cells was approved by the patients and the Ethics Committee of the University of Munich. All patients were treated following standard IVF protocols and negatively diagnosed for the polycystic ovary syndrome. To account for patient-to-patient variations all studies were performed on several, randomly selected cell preparations (pooled from up to 3 patients) on different days.

Human tissue samples

Human ovarian samples containing CL from consenting patients undergoing gynecological surgery (generously provided by C. Heiss, Klinik am Eichert, Göttingen, Germany) were fixed in Bouin's fixative and embedded in paraffin. Apart from this, we used paraffin-embedded ovarian samples with follicles from the tissue archive of the Women's Hospital in Munich, which had been taken from pre-menopausal women during autopsies [34]. The Ethics Committee of the University of Munich approved all procedures concerning use of human materials. Pathological deterioration of follicles and corpora lutea in these human ovarian samples were excluded by morphological and microscopical assessment.

Chemicals and solutions

A stock solution of apamin (Alomone Labs, Jerusalem, Israel) was prepared in distilled water. TRAM-34 (1-[(2-Chlorophenyl)diphenylmethyl]-1H-pyrazole; Sigma-Aldrich) was dissolved in DMSO (10 mM) and final
DMSO concentration in the cell culture medium did not exceed 0.01% (v/v).

**Progesterone assay**

Progesterone concentrations were measured in supernatants of human GCs cultured in 24-well plates. On day three of culture, cells were treated in triplicates with the respective compounds. After 24 h the supernatants were collected and the progesterone concentrations were measured using an ELISA (DRG Instruments, Marburg, Germany). Experiments were repeated with cells from independent cell preparations (each pooled from up to 3 patients) to account for interpatient variability. After normalization to the respective control (untreated) values, data were statistically analyzed by a repeated measures ANOVA followed by Newman-Keuls multiple comparison test.

**Electrophysiology**

Human GCs were grown on glass cover slips for 2–12 days and currents were recorded at room temperature by means of an EPC-9 amplifier (HEKA elektronik, Lambrecht, Germany; sample rate, 10 kHz; low pass filter, 2.5 kHz) [8]. Positive currents represent outward currents and all potentials given refer to the cytoplasmic side of the plasma membrane. Potentials were corrected for a liquid junction potential of +16 mV [35]. The extracellular solution (EC) contained (in mM) 140 NaCl, 3 KCl, 1 CaCl$_2$, 1 MgCl$_2$, 10 Hepes, and 10 glucose (pH 7.4). The intracellular solution (IC) contained (in mM) 130 K-gluconate, 5 NaCl, 2 EGTA, 1 MgCl$_2$, and 10 Hepes (pH 7.4). Single channel currents were recorded in the inside-out configuration. To assess the Ca$^{2+}$-sensitivity of the BK$_{Ca}$ channel the free Ca$^{2+}$ concentration [Ca$^{2+}$]$_i$ of the IC solutions was used: 1.000 mM ([Ca$^{2+}$]$_i$ = 100 nM), 1.870 mM ([Ca$^{2+}$]$_i$ = 1 μM), 1.977 mM ([Ca$^{2+}$]$_i$ = 5 μM), 1.996 mM ([Ca$^{2+}$]$_i$ = 10 μM), 2.013 mM ([Ca$^{2+}$]$_i$ = 20 μM), 2.100 mM ([Ca$^{2+}$]$_i$ = 100 μM), and 3.000 mM ([Ca$^{2+}$]$_i$ = 1 mM), respectively. Single channel currents were recorded in the inside-out configuration. To assess the Ca$^{2+}$-sensitivity of the BK$_{Ca}$ channel the free Ca$^{2+}$ concentration [Ca$^{2+}$]$_i$ of the IC solutions was adjusted by using varying concentrations of CaCl$_2$, according to calculations performed by means of the software "Calcium" [36]. The following CaCl$_2$ concentrations were used: 1.000 mM ([Ca$^{2+}$]$_i$ = 100 nM), 1.870 mM ([Ca$^{2+}$]$_i$ = 1 μM), 1.977 mM ([Ca$^{2+}$]$_i$ = 5 μM), 1.996 mM ([Ca$^{2+}$]$_i$ = 10 μM), 2.013 mM ([Ca$^{2+}$]$_i$ = 20 μM), 2.100 mM ([Ca$^{2+}$]$_i$ = 100 μM), and 3.000 mM ([Ca$^{2+}$]$_i$ = 1 mM), respectively. To obtain channel current-voltage relationships a voltage protocol ranging from -80 mV to +90 mV in 10 mV steps was used with each potential applied for 200 ms. For evaluation of channel open probability $P_o$, single channel currents were recorded at +60 mV, +70 mV, +80 mV, and +90 mV for 1600 ms in each case. For analysis, frequency histograms of current traces were calculated and the two amplitude peaks corresponding to open and closed channel state were fitted using Gaussian distributions. The single channel current amplitude was measured as differences between the two peaks. Integration of the area under the curves and division of the area under the open channel peak by the area under the entire curve yielded $P_o$.

**RT-PCR**

Total RNA was isolated from several human GC preparations, and reverse transcribed using Superscript-RT II (Life Technologies, Karlsruhe, Germany) in combination with either a 18-mer polydeoxynucleotidic primer or random hexamers of polydeoxynucleotide primers. PCR amplification was carried out with oligodeoxynucleotide primer pairs, which spanned at least one intron of the genomic sequence (except for the second BK β1 primer pair; Table 1) [37,38]. The PCR protocol consisted of 35 cycles of denaturation at 94°C (30 s), annealing at the temperatures given in Table 1 (30 s), and elongation at 72°C (45 s) using a PTC-200 Peltier Thermal Cycler (MJ Research, Bio-Rad, Munich, Germany). PCR products were separated on an agarose gel and visualized by ethidium bromide staining and ultraviolet illumination. Identity of all PCR products was verified by sequencing (Agowa, Berlin, Germany).

**cDNA array**

Total RNA of GCs cultivated for 3 days was isolated and subjected to the GEArray Q Series Human Neuroscience-1 Ion Channel and Transporter Gene Array (SuperArray Bioscience Corp., Frederick, MD). The cDNA array was analyzed by means of a chemiluminescent detection method (Roche Diagnostics, Mannheim, Germany) [39].

**Immunohistochemistry**

Localization of $K_{Ca}$ α subunit proteins in human ovarian sections (5 μm) was examined according to standard procedures [34,40]. Antisera were purchased from Alomone Labs (Jerusalem, Israel) and utilized in the denoted dilutions: anti-$K_{Ca}$C,3.1 (K; rabbit anti-human; 1:200), anti-SK1 (rabbit anti-rat; 1:200), anti-SK2 (rabbit anti-rat; 1:200), anti-SK3N (rabbit anti-human; 1:500), and anti-SK3C (rabbit anti-human; 1:500). The deparaffinized sections were subjected to an additional microwave treatment for improved antigen retrieval [40] and treated with 3% H$_2$O$_2$ in methanol to block endogenous peroxidase. Thereafter slices were incubated at 4°C overnight with the respective antisera (containing 5% normal goat serum) and finally with goat anti-rabbit antibody (1:500). Immunoreactivity was visualized by the ABC-diaminobenzidine staining reaction (Vectastain Elite Kit, Vector Laboratories, Germany).

Primer sequences were derived from the PrimerBank (ID; http://pga.mgh.harvard.edu/primerbank; [37], from the literature, or designed using the software Lasergene (DNASTar; see source).
Peterborough, UK) [34,40]. Specificity of the immunoreaction was assured by either pre-adsorption of the first antiserum with a specific peptide antigen, or its replacement by normal rabbit serum, or its complete omission.

**Cytotoxicity assays**
Potential cytotoxicity of the channel blockers was evaluated by using commercial non-radioactive cell proliferation assays (CellTiter and CellTiter-Glo, both from Promega, Mannheim, Germany) [11]. Human GCs were cultured in 24- or 48-well plates and treated in triplicates for 24 h on day 3 of culture with the substances applied for progesterone measurements.

**Data analysis**
Data were analyzed and depicted using Prism 4 (GraphPad Software, San Diego, California) and SigmaPlot 10 (SPSS, Chicago, Illinois). Data represent means ± SEM if not stated otherwise.

**Results**

**Role of KCa channels in steroidogenesis in human GCs**
Functionality of BK Ca channels is known to be necessary for steroidogenesis in human GCs [8]. Blocking of IK channels by TRAM-34 (1 μM) and of SK channels by apamin (100 nM) had an inhibitory action on hCG (10 IU/ml)-induced progesterone production as well (Figure 1). The blockers had no effect on basal progesterone production. This casts cytotoxic actions of the blockers into doubt. In addition, neither two different proliferation/cytotoxicity assays nor inspection of the cells by light and electron microscopy showed any detrimental alterations caused by the KCa blockers (data not shown).

**Expression of different KCa channel families in human GCs**
The presence of mRNAs coding for all known types of SK channels and the IK channel was demonstrated by cDNA arrays (except for SK2) and by RT-PCR followed by sequencing (Figure 2A). In case of SK1 two PCR products were found and sequenced, which both correspond to the respective channel. They differ with regard to presence or absence of exon 9 (the primers match sequences in exon 8 and 10, respectively) and are, thus, most likely yet unknown splicing variants. IK and SK2 α subunit proteins are expressed in GCs of the human ovary (Figure 2). Expression of SK1 and SK3 α subunits cannot be unambiguously appraised since the antisera used for immunohistochemistry produced unspecific (e.g. nuclear) staining (data not shown).

In electrophysiological recordings in the inside-out configuration, a second type of KCa channel besides the BKCa was recorded at [Ca2+]i > 1 μM (Figure 3). This channel is most likely the IK channel because of its characteristic intermediate single-channel conductance of 67 ± 5 pS and a reversal potential of $V_0 = 7$ mV under symmetrical K+-gluconate concentrations (n = 5; Figure 3B), its increasing $P_o$ with rising [Ca2+]i (data not shown), and because K+ was the only permeant ion present in sufficiently high concentrations on both sides of the membrane. The maxiCl can be excluded due to the low symmetrical Cl--concentrations of 9 mM. In almost all recordings exhibiting the IK channel, at least one BKCa channel was simultaneously active (Figure 3A).

**Ca2+- and voltage-dependence of BKCa channels in human GCs**
BKCa channels recorded in the inside-out configuration exhibited a characteristic single channel conductance in the range of 200 pS. Channel open probability $P_o$ increased with both elevating [Ca2+]i and voltage (Figure 4). The Ca2+-dependence of the BKCa was evaluated by fitting $P_o$ as a function of [Ca2+]i with a sigmoidal dose-response curve (Figure 4B). The [Ca2+]i for half-maximal activation were EC50 (60 mV) = 20 μM (9 to 41 μM; n = 30), Hill slope = 1.0 μM (0.5 to 1.5 μM), and EC50 (70 mV) = 12 μM (6 to 24 μM; n = 30), slope = 0.8 μM (0.3 to 1.4 μM). Comparing individual cells, heterogeneity of EC50 values – even in the same cell preparation – was observed. The values covered a range of 2 to 118 μM (at +60 mV; n = 8) and of 1 to 91 μM (at +70 mV; n = 9), respectively. At high [Ca2+]i (1 mM) and high positive
potentials (+70 mV) inactivation of BKCa channels was observed for time periods ranging from several hundred ms to several s (Figure 4C). Periods of inactivation longer than 500 ms were not considered when calculating Po; only the trace before onset of inactivation was evaluated.

The voltage-dependence of the BKCa channel was determined at high [Ca2+] because at lower [Ca2+] the channel was not active at negative potentials. By fitting the data with a Boltzmann sigmoidal function a potential for half-maximal activation of $V_{50} = -54$ mV (-56 to -51 mV, 95%-C.I.) and a slope factor of +12 mV (+9 to +15 mV) were observed at [Ca2+] = 1 mM (n = 4; Figure 4D).

Expression of BKCa β subunits in human GCs
By RT-PCR and subsequent sequencing, we identified mRNAs encoding the BKCa subunits β2, β3, and β4 in human GCs (Figure 5A). The β1 subunit was not detected using two different primer pairs, which amplified the β1 subunit in positive control tissues (ovary, prostate, testis, colon, heart, and lung; data not shown). The BKCa β4 subunit protein was also found in endocrine cells of the human CL by means of immunohistochemistry (Figure 5B).

Discussion
In the present communication we report that human GCs possess in addition to the BKCa other functional KCa channels. The detection of mRNAs encoding the intermediate-conductance KCa (IK) as well as all three known types of small-conductance KCa (SK1, SK2, SK3) points at a complex KCa repertoire. The finding of mRNA alone can be misleading as was shown in a study on glioma cells in which mRNAs for...
Figure 4
Electrophysiological characterization of Ca^{2+}- and voltage-dependence of BK_{Ca} channels in human GCs (inside-out recordings). (A) BK_{Ca} current traces recorded at +60 mV and varying [Ca^{2+}], (right). The closed channel state (c) corresponds to the respective lower current level (o, open state). (B) Ca^{2+}-dependence of the channel open probability, P_{o}, at +70 mV. Data (black circles) represent means ± SEM of recordings from 30 cells and were fitted by a sigmoidal dose-response function with the bottom value fixed to be 0. EC_{50} = 12 μM, Hill-slope = +0.8 μM (n = 30). Gray circles and fit curves show data from two individual recordings that represent extrema of Ca^{2+}-dependence of P_{o}. (C) BK_{Ca} channel inactivation at [Ca^{2+}] = 1 mM and +70 mV. (D) Voltage-dependence of P_{o} at [Ca^{2+}] = 1 mM (V_{50} = -54 mV, n = 4). Data were fitted by a Boltzmann sigmoidal function with bottom value fixed to be 0.
all KCa channels were detected, although only BKCa channels were functional [41]. However, in human GCs all three classes of KCa channels are functional, because specific blockers attenuated hCG-stimulated steroidogenesis. The IK blocker TRAM-34 was recently reported to inhibit nonselective cation channels as well [42], but is still one of the most accepted pharmacological tools to block IK channels. We cannot definitely exclude a role of nonselective cation channels. However, as they were not found in human GCs so far and because we presented further molecular proof of IK presence, we interpret the TRAM-34 action as blockage of IK channels. We now be better interpreted in terms of a GCs contribution to the mRNA findings [29,31].

The consequences of BKCa β subunit expression pattern for channel function in human GCs are difficult to compare with studies in cellular model systems expressing only one type of β subunit. Nevertheless, the β subunit repertoire found on the mRNA level might help to explain our observations. The recorded inactivation of BKCa channels at high positive potentials and at high free [Ca2+]i was reported to occur in the presence of β2 and/or β3 subunits [26-28,52,53]. The absence of the β1 subunit might explain why oestrogens do not activate the BKCa in human GCs [8]; in contrast to myometrial smooth muscle in which activation by oestrogens was ascribed to the presence of β1 [54,55]. The presence of β4 should introduce IbTx-resistance to BKCa channels [32]. However, the fact that IbTx blocks both BKCa whole-cell currents and hCG-stimulated steroidogenesis. 

(B) BKCa β4 subunit protein is present in GCs of human CL. Bar, 50 μm.

Figure 5

(ACH, oxytocin, relaxin, norepinephrine, dopamine, ATP) that are known to alter [Ca2+]i [10-12]. Therefore, and because the BKCa is the best studied KCa channel, we assessed its Ca2+- and voltage-dependence by means of single-channel recordings. The BKCa channel was half-activated at about 20 μM [Ca2+]i, at +60 mV. An increase of [Ca2+]i by one order of magnitude is known to shift the potential V50 necessary for half-maximal activation in several other cell types by about 50 mV (30 to 94 mV) to more negative values [43-45]. At a global [Ca2+]i = 1 μM that can be reached by stimulation with ACh, oxytocin, or relaxin [8-10], the potential V50 necessary for half-maximal activation can be estimated to equal +100 mV. Although this represents a rather non-physiological voltage value, BKCa channels can be activated under physiological conditions in human GCs since its specific blocking with IbTx attenuates hCG-stimulated progesterone production [8]. This apparent discrepancy might be explained by the fact that open probabilities much lower than 50% could account for physiologically sufficient macroscopic (whole-cell) currents. In addition, during stimulation local rises in [Ca2+]i in close proximity to the channel might be much higher than the monitored overall cytoplasmic elevation of [Ca2+]i and thereby BKCa channels can be opened at more physiological voltages. Pronounced differences in alteration of global [Ca2+]i monitored by standard techniques and of local [Ca2+]i, were described in other cell types [46,47].

The variability of EC50 values for Ca2+-sensitivity of the BKCa channel over two orders of magnitude could be due to different β subunits present since they are known to be important modulators of Ca2+- and voltage-sensitivity of the channel [25-32,48]. Similar variations of EC50 and half-maximal activation voltages were reported for BKCa in other cell types [13,15,43,45,49-51]. Therefore, we have studied the BKCa β subunit expression in human GCs and found mRNAs encoding the accessory subunits β2, β3, and β4, but not β1. Reports on the presence of β2, β3 and β4 mRNAs in material from whole human ovaries can now be better interpreted in terms of a GCs contribution to the variability of EC50 values for Ca2+-sensitivity of the BKCa channel.

Reports on the presence of β2, β3 and β4 mRNAs in material from whole human ovaries can now be better interpreted in terms of a GCs contribution to the mRNA findings [29,31].
stimulated progesterone production points at a more complex picture, i.e. at least a proportion of the BKCa channels in human GCs is IbTx-sensitive and, thus, probably contains not only β4 [8].

The simultaneous presence of different KCa types is known from other cell types [18]. But what could be the cellular relevance of the ostensibly redundancy to have different KCa channels? They differ regarding regulation, biophysical properties as well as Ca2+ sensitivity with IK and SK channels being activated at lower [Ca2+]i than the BKCa [17,18]. In addition, the BKCa is voltage-sensitive in contrast to other KCa channels [13,14,16,24], which would allow differentiated responses to the same Ca2+ signals at varying membrane potentials. Concerning the multitude of KCa channels in human GCs the question arises whether each individual GC expresses all identified KCa channel subunits in parallel. The RT-PCR and progesterone production experiments can provide no answers about single cells. But single channel recordings revealed that at least BKCa and IK channels can be present in the plasma membrane of the same individual cells. However, it is very likely that individual GCs can exhibit a varying KCa repertoire and that GC subpopulations might exist regarding the expression of β subunits. Immunohistochemical results are in favor of such an assumption, since for IK, SK2, and β4, the degree of immunostaining in GCs of the human CL varies. The variations in Ca2+-sensitivity observed in single BKCa channel recordings might also reflect BKCa heterogeneity in single GCs and/or between individual GCs.

Conclusion

In summary, we found expression (in vitro, ex vivo) of several classes of KCa channels in human GCs, which are all involved in gonadotropin-stimulated sex steroid hormone production. The presence of different KCa channels and the observed heterogeneity in Ca2+-sensitivity of the BKCa channel, which is probably due to expression of various β subunits, could allow finely tuned and differentiated cellular responses over a wide [Ca2+]i range. The question of existence of GCs subpopulations regarding KCa channels and BKCa β subunits has to be studied in the future to understand cellular processes on the level of individual GCs. The rich instrumentation of Ca2+-dependent channel antagonists influence porcine granulosa cell proliferation, differentiation, and apoptosis. Biol Reprod 2002, 67:88-98.

We would like to thank A. Krieger, C. Roggers, A. Tiefenbacher, A. Domokos, C. Mayer, B. Zschieche, and G. Prechtnert for expert technical help. Human tissue samples were generously provided by C. Heiss (Klinik am Eichert, Goppingen, Germany). The study was supported by the DFG (German Research Foundation; ‘Graduiertenkolleg 333’ and MA 1080/17-1).
