\textbf{Background}: Tong-fu therapeutic method (TFTM) is a traditional Chinese medicine treatment method for ulcerative colitis, which is a novel treatment strategy and have purgative effect. As the most representative medicinal of TFTM, Rhubarb has been reported to have a therapeutic impact on ulcerative colitis by regulating intestinal flora, anti-inflammation, and improving intestinal microcirculation. Although rhubarb has been widely used in Chinese medicine for the treatment of ulcerative colitis, the appropriate protocol is still demanded to its rational use in clinic, which promoted to evaluate the efficacy and safety for rhubarb-based therapy on ulcerative colitis.

\textbf{Method}: Clinical trials were searched through PubMed, Cochrane Library, Web of Science, Excerpta Medica Database, Chinese National Knowledge Infrastructure, WAN FANG Database, Chinese Scientific Journal Database, and Chinese Biomedical Literature Database. The subgroup analyses were performed with three groups: medication, course of treatment, and route of administration. The statistical analyses were performed on Review Manager software (version 5.4.1).

\textbf{Results}: A total of 2, 475 patients in 30 original studies were analyzed in this article. It was found that rhubarb-based therapy could increase clinical efficacy

\textbf{Abbreviations}: CBM, Chinese Scientific Journal Database; CNKI, Chinese National Knowledge Infrastructure; CRP, C-reaction protein; EMBASE, Excerpta Medica Database; FIB, fibrinogen; IBD, inflammatory bowel disease; IL-6, interleukin-6; PLT, platelet; PT, prothrombin time; RCTs, Randomized clinical trials; TCM, traditional Chinese medicine; TFTM, Tong-fu therapeutic method; TNF-\textalpha, tumor necrosis factor-\textalpha; UC, Ulcerative colitis; XXD, Xiexin decoction.
and reduce the recurrence rate. Subgroup analyses showed that rhubarb-based therapy was more effective than 5-aminosalicylic acid or sulfasalazine alone. In addition, the hypercoagulable state of ulcerative colitis could be ameliorated by decreasing platelet (PLT) and fibrinogen (FIB), and increasing prothrombin time (PT) significantly. Moreover, C-reaction protein (CRP), tumor necrosis factor-α (TNF-α), interleukin (IL)-6, IL-8, and IL-1β expression were significantly reduced, while IL-10 production was increased, which mediated the alleviation of intestinal inflammation stress.

**Conclusion:** Rhubarb-based therapy could effectively improve ulcerative colitis. Of note, the rhubarb-based medicinal formulas combined with 5-ASA or SASP are more effective than the 5-ASA or SASP alone. In addition, although rhubarb has side effect, the results of our analysis showed that rhubarb-based therapy did not exhibit significant side effects. This means it has a high safety profile in clinical use. Moreover, the use of rhubarb-based therapy is recommend to use within 1–13 weeks or 3 months via administered orally or by enema, which is contributes to ensure the curative effect and avoid its toxic and side effects. As an important case of TFTM, rhubarb-based therapy provides evidence for the practical application of TFTM.

**Introduction**

Ulcerative colitis (UC) is a subtype of inflammatory bowel disease (IBD). The prevalence of IBD in the western world has reached as high as 0.5% of the total population (Kaplan, 2015). UC has evolved into a global burden given its high incidence in developed countries and the substantial increase in incidence in developing countries (Sood et al., 2003; Molodecky et al., 2012; Kobayashi et al., 2020). Even though the pathogenesis of UC has not been revealed ultimately, immunological abnormalities are considered to play an essential role, and drugs regulating the innate immune system have become the mainstream treatment. 5-aminosalicylic acid (5-ASA), corticosteroids, and thiopurines can effectively alleviate UC as first-line therapeutic agents (Kobayashi et al., 2020). However, several limitations of the treatments have attracted increasing attention. 5-ASA is beneficial to mild to moderate UC but undesirable for severe UC. Meanwhile, corticosteroids, as a supplement to 5-ASA, are considered to lack long-term efficacy and safety. The application of thiopurines is challenged with increasing evidence of potential serious adverse reactions such as bone marrow and liver toxicity, pancreatitis, increased risk of non-melanoma skin cancer and lymphoma (Ko et al., 2019; Kobayashi et al., 2020). Due to the lack of satisfactory treatment, UC patients relapse continually even after routine treatment (Kobayashi et al., 2020). In essence, more effective treatment options with less adverse reactions still expected.

Tong-fu therapeutic method (TFTM) as an important traditional Chinese medicine therapy, can produce purgative effect and restore gastrointestinal motility. According to traditional Chinese medicine (TCM) theory, TFTM can descend qi, which discharges toxic and harmful products, breaks the vicious circle caused by toxin retention, improves intestinal microcirculation, and regulates the internal environment of the host, to treat and prevent the deterioration of the disease. Study has demonstrated that TFTM, whenever administered orally, rectally, or by nasal feeding, can improve gastrointestinal dysfunction and reduce case-fatality rate (Zhang et al., 2021). Rhubarb (*Rheum palmatum* L.) [dà huáng; Polygonaceae; *Rheum palmatum* root and rhizome], as one of the most representative medicinals of TFTM, was first recorded in *Shén Nóng’s Classic of the Materia Medica (Shén Nóng Běn Cáo Jing)*, which can play a powerful role in TFTM and improve digestive diseases (Teng et al., 2019). It was referred that rhubarb combined with conventional medication (somatostatin or trypsin inhibitor) in the treatment of acute pancreatitis was superior to conventional medication alone (Zhou et al., 2016; Hu et al., 2018). Also, rhubarb could modulate gut microbiota, which indirectly changed purine Metabolism in the intestine and subsequently alleviated DSS-induced chronic colitis (Wu et al., 2020). Additionally, rhubarb acted as an anti-platelet (PLT) aggregator that could significantly alleviate the hypercoagulable state associated with UC (Gao et al., 2020). In general, the rhubarb-based therapy is effective and authentic in improving UC, and its underlying mechanism appears to be multifaceted and meaningful. Presently, a large number preclinical and clinical evidence has clarified the positive effect...
of rhubarb and the rhubarb-based medicinal formulas on UC, however, the evidence is scattered. Because the influence of TFTM represented by rhubarb on UC has not been systematically supported by evidence-based medicine analysis, its scientific validity and potential clinical value have not been fully revealed. In this paper, a Meta-analysis of rhubarb-based therapy is conducted to assess the efficacy and safety. Meanwhile, the mechanisms of rhubarb improving hypercoagulable state of UC was systematically reviewed. Through the analysis and systematic review, it was given that a reliable application protocol of the rhubarb-based therapy could ensure the curative effect and its mechanism.

Methods

This study was conducted following Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement (Moher et al., 2009). The requirements considered relevant in recent best practice guidelines for manuscripts of natural products have been taken into account (Heinrich et al., 2020).

Search strategies

The search of the original studies was carried out until 7 October 2021 through Chinese National Knowledge Infrastructure (CNKI), the WANFANG Database, the Chinese Scientific Journal Database (VIP), the Chinese Biomedical Literature Database (CBM), Excerpta Medica Database (EMBASE), Web of Science, PubMed, and Cochrane Library. The medical subject headings were "ulcerative colitis" and "Rheum."

The search formulation adopted a combination of free texts and medical subject headings (MeSH). According to the search habits of each database, the retrieval method that met the requirements was developed. The search formulas for each database are shown in Supplementary Data S1. At the same time, there is no restriction of search formulation on language or country.

Study selection

Type of participants

In this study, all participants met the UC diagnostic criteria. As there is no gold standard for UC diagnosis, patients were subjected to comprehensive analysis, including symptom evaluation, endoscopic examination, and histopathological manifestations (Ungaro et al., 2017). Specifically, patients with a definite diagnosis of UC were included in the study and those with Crohn’s disease or unspecified IBD subtypes were excluded.

Type of interventions

Interventions in the treatment group were rhubarb-based therapeutic regimen, including rhubarb-based medicinal formulas alone or combined with UC routine treatment, including 5-ASA, sulfasalazine (SASP), olsalazine sodium, bifidobacterium triple viable capsules, glutamine, infliximab, prednisolone, hydrocortisone sodium succinate, and by oral or enema. Patients in the control group were treated with UC routine treatment. The trial was excluded if external TCM treatments such as acupuncture, massage, and moxibustion were present in the treatment group.

Type of outcome measures

Outcomes were divided into main outcome and secondary outcomes. The primary outcome was the clinical efficiency. The Mayo score, Geboes score, recurrence rate, PLT, adverse events, symptoms integral, and inflammatory cytokines and protein, including C-reaction protein (CRP), tumor necrosis factor-α (TNF-α), Interleukin (IL)-6, IL-8, IL-1β, and IL-10 were the secondary outcomes.

Type of studies

Randomized clinical trials (RCTs) were selected for Meta-analysis. Animal experiments, non-randomized controlled trials, and repeated data studies were excluded.

Data extraction

Firstly, YL was responsible for formulating retrieval strategies and extracting retrieval records. Secondly, ZY and YH, and QZ independently screened the title and abstract of the articles, excluding the content that did not meet the standard. After combining the two results, YL, HH, and LC entered the full-text screening stage. When they encountered differences, the literatures were handed over to MW and CZ for judgment. In the end, from the included studies, information was extracted by two reviewers: HQ extracted the data, and YL was in charge of reviewing it.

Assessment of the risk of bias

Based on the Cochrane Handbook, YL and HH independently assessed the bias risk of each study. The standard included the following seven items: 1) sequence generation (selection bias); 2) allocation concealment (selection bias); 3) blinding of participants and personnel (performance bias); 4) blinding of outcome assessments (detection bias); 5) incomplete outcome data (attrition bias); 6) selective reporting (reporting bias); 7) other sources of bias. On the basis of methodological quality, the studies were classified as high risk, low risk, and unclear risk in each domain.
Data analysis

Meta-analysis was performed by Review Manager (V.5.4.1 Copenhagen: The Nordic Cochrane Centre, The Cochrane Collaboration, 2021). Depending on the result category, the risk ratio (RR) and 95% confidence interval (CI) were used to calculate the categorical data, and the weighted mean difference (WMD) and 95% CI were used to calculate the continuous data. \(p < 0.05\) was considered statistically significant. Heterogeneity was estimated by Cochran’s Q test and assessed using \(I^2\). When \(I^2 > 50\%\), it is considered to have significant heterogeneity and a random-effects model is used to estimate the pooled effect. In contrast, a fixed-effects model was used. Besides, if there were heterogeneity in the results, we would look for heterogeneity sources and perform a sensitivity analysis by converting the random effect model and fixed effect model to determine whether the results are stable. Publication bias was analyzed visually through funnel plots.

Association rules of Chinese medicinals were analyzed by SPSS Modeler 18.0. Cytoscape V3.9.0 established the topological network.

Results

Study identification

Based on the search strategy, 2,475 potential associated articles were obtained by searching the databases. After deleting 95 repetitive articles, 2,380 articles were obtained. In the process of title and abstract screening, a total of 2,074 articles were excluded due to not meeting the inclusion criteria, and 306 papers were searched for further evaluation. Finally, 30 studies were finally retained for this Meta-analysis (Nong, 2009; Li, 2012; Deng, 2015; You et al., 2015; Ding, 2016; Wang, 2016; Zhang, 2016; Fei, 2017; Sheng)
et al., 2017; Shi and Sun, 2017; Tian, 2017; Wang et al., 2017; Wen and Sun, 2017; Yang et al., 2017; Wang, 2018; Guo and Ding, 2019; Li, 2019; Liu, 2019; Chen and Li, 2020; Deng and Chen, 2020; Sun and Zhang, 2020; Tan et al., 2020; Wang, 2020; Yuan, 2020; Zhang, 2020; Zhao, 2020; Li et al., 2021; Xue and Xu, 2021; Yang and Wang, 2021; Yin et al., 2021). Exclusive reasons are shown in Figure 1.

Study characteristics

Supplementary Table S1 shows the general characteristics of 30 studies. A total of 2,507 patients were included from 2009 to 2020, with 1,257 cases in the treatment group and 1,250 cases in the control group. 5-ASA was selected as the control group measure in 20 studies, SASP in seven studies. The rhubarb-based medicinal formulas were used alone in the treatment group for four studies. And the rest are in combination with the UC routine treatment. All 30 studies were conducted in China.

Risk of bias

Figure 2 shows the methodological quality of 30 studies. The risk of bias in the study was evaluated according to the criteria in the Handbook for Systematic Evaluation of Cochrane Interventions (Higgins et al., 2011).

All studies mentioned “randomness” and described the specific random assignment method for random sequence generation and were therefore judged as low risk. None of the studies described allocation concealment, blind of participants and personnel, or blind of outcomes, so the risks were unknown. Since the pre-registered protocols could not be acquired from the main authors, the selective report was rendered as unknown. Other risks of bias were also considered unclear.

Primary outcome

Clinical efficiency

The clinical efficiency was recorded in 29 trials. There was no heterogeneity among studies, and a fixed-effects model was used for analysis. The Meta-analysis results showed that the clinical efficiency of rhubarb-based treatment group was significantly higher than that of control group (n = 2421, I^2 = 0%, RR = 1.24, 95% CI [1.20, 1.29], p < 0.00001) (Figure 3). Next, the subgroup analyses were performed.

To further analyze the effect of rhubarb-based medicinal formulas alone or combined with first-line drugs 5-ASA, SASP, or other different routine drugs in the experiment, the clinical efficiency was selected for subgroup analysis. There was no heterogeneity among the studies. A fixed-effect model was selected for Meta-analysis.

In the treatment group, 16 studies combined with 5-ASA (n = 1456, I^2 = 0%, RR = 1.22, 95% CI [1.16, 1.27], p < 0.00001) (Figure 4), six studies combined with SASP (n = 430, I^2 = 0%, RR = 1.27, 95% CI [1.17, 1.38], p < 0.00001) (Figure 4), three studies combined with other routine drugs (n = 208, I^2 = 0%, RR = 1.24, 95% CI [1.10, 1.39], p = 0.0003) (Figure 4), and four studies were conducted by the rhubarb-based medicinal formulas administered alone (n = 327, I^2 = 43%, RR = 1.32, 95% CI [1.18, 1.47], p < 0.00001) (Figure 4). Compared with the control group, the clinical efficiency of the treatment group was significantly higher. The rhubarb-based medicinal formulas alone or combined with common drugs showed good therapeutic effects.

Among the 29 studies, 21 were treated with rhubarb-based therapy oral administration and seven were treated with enema. Statistical analysis showed that no matter oral administration (n = 1318, I^2 = 0%, RR = 1.25, 95% CI [1.19, 1.30], p < 0.00001) (Figure 5) or enema administration (n = 496, I^2 = 0%, RR = 1.24, 95% CI [1.15, 1.34], p < 0.00001), the clinical efficiency was significantly improved (Figure 5).

The course of the treatments is one of the factors affecting the efficacy. In the studies where total effective rates were reported, treatment courses were divided into 2–5 weeks (n = 14);
6–9 weeks (n = 11) or 12–13 weeks (n = 4). None of these analyses showed heterogeneity, so the fixed effects model was chosen for the Meta-analysis. The results showed that the clinical efficiency significantly increased at 2–5 weeks (n = 1180, I² = 0%, RR = 1.21, 95% CI [1.15, 1.28], p < 0.00001) (Figure 6), 6–9 weeks (n = 924, I² = 0%, RR = 1.27, 95% CI [1.20, 1.35], p < 0.00001) (Figure 6), and 12–13 weeks (n = 317, I² = 0%, RR = 1.24, 95% CI [1.13, 1.37], p < 0.0001) (Figure 6).

Secondary outcomes

**Mayo score**

Three trials reported Mayo score. The random-effect Meta-analysis showed that the Mayo score in the treatment group was significantly lower than that in the control group (n = 254, I² = 88%; MD = −1.28; 95% CI [−2.09, −0.46], p = 0.002) (Figure 7). The sensitivity analysis showed that the study reported by Yin P. was the source of heterogeneity. Excluding this study reduced the inter-study heterogeneity (I² = 0%).

**Geboes score**

The Geboes score was assessed in three studies. The heterogeneity among studies was obvious, so the random-effect model was used for Meta-analysis. A significant reduction in Geboes scores was seen in the treatment group compared to the control group. (n = 336, I² = 89%; MD = −0.48; 95% CI [−0.59, −0.36], p < 0.00001) (Figure 7). According to sensitivity analysis, the source of heterogeneity was reported by Li Z.W. After excluding this study, heterogeneity was reduced to I² = 0%.

**Recurrence rate**

Three studies evaluated the reduction in recurrence rate. There was no heterogeneity among studies. The fixed-effects model was used in the analysis. The results revealed that the rhubarb-based treatment could significantly reduce the recurrence rate of UC patients compared with the control group (n = 215, I² = 0%. RR = 0.27; 95% CI [0.11, 0.63], p = 0.003) (Figure 8).
PLT

PLT increase was evaluated in three trials. There was no heterogeneity among the studies, and the fixed-effects model was used in the analysis. The results showed that the rhubarb-based treatment could reduce PLT levels compared with the control group ($n = 226$, $I^2 = 0\%$. RR = $-32.95$; 95% CI $[-39.21, -26.69]$, $p < 0.00001$) (Figure 9). Furthermore, it could also influence the coagulation-related indexes of prothrombin time (PT) and fibrinogen (FIB) (Supplementary Figure S1).
Inflammatory cytokines and protein

The regulation of cytokines towards multiple inflammatory signaling pathways are the central component of chronic inflammation in UC. IL-6, one of the major cytokines, can bind to IL-6R to activate STAT3 signaling and further induce differentiation of Th17 cells, leading to excessive release of pro-inflammatory cytokines such as IL-17 and IL-22 (Waldner and Neurath, 2014). IL-6 also stimulates the production of the regulatory inflammatory marker C-reactive protein (CRP) (Pepys and Hirschfield, 2003). Meanwhile, the synergy effect of IL-1β, IL-23, and IL-6 strengthens Th17 cell differentiation and maintains the expression of pro-inflammatory cytokines (Chung et al., 2009). Moreover, IL-6 and IL-8, as inducers of neutrophil recruitment, can amplify the inflammatory response by interacting with a large number of inflammatory cells exuding from inflamed areas (Kim and Kim, 2010; Waldner and Neurath, 2014). TNF-α stimulates death receptor signaling leads to excessive crypt cell death, which increases the intestinal inflammatory response ( Günther et al., 2011). The results showed that the rhubarb-based therapy significantly reduced the level of IL-6 (n = 794, I² = 99%. MD = −18.60; 95% CI [−24.51, −12.68], p < 0.00001) (Figure 10A), IL-8 (n = 718, I² = 99%. MD = −25.44; 95% CI [−34.36, −16.52], p < 0.00001) (Figure 10B), IL-1β (n = 494, I² = 97%. MD = −4.92; 95% CI [−6.69, −3.16], p < 0.00001) (Figure 10C), TNF-α (n = 1243, I² = 99%. MD = −13.08; 95% CI [−17.18, −8.98], p < 0.00001) (Figure 10D), and CRP (n = 311, I² = 98%. MD = −3.97; 95% CI [−6.22, −1.73], p = 0.0005) (Figure 11A) when compared with the control group. Overall, IL-6, IL-8, IL-1β, and TNF-α are all considered to be essential mediators of chronic intestinal inflammation, and the rhubarb-based treatment showed a better effect on pro-inflammatory cytokines.

Besides, the relative deficiency of IL-10 in UC patients may contribute to persistent inflammatory changes (Wang et al., 2020). IL-10 down-regulates the production of Th1-derived cytokines to exert anti-inflammatory effects (Glocker et al., 2003). Meanw
The pooled analysis suggested that the difference between the two groups was statistically significant ($n = 258$, $I^2 = 92\%$, MD $= 11.26$; 95% CI $[6.50, 16.01]$, $p < 0.00001$) (Figure 11B).

### Adverse events

Six studies reported adverse reactions. Nevertheless, the results were not statistically significant ($n = 521$, $I^2 = 33\%$, RR $= 0.71$, 95% CI $[0.41, 1.23]$, $p = 0.22$) (Figure 12A). Due to the different courses of treatment, another subgroup analysis was set up. After 6–9 weeks of administration, rhubarb-based therapy had an obvious effect on reducing the incidence of adverse events ($n = 180$, $I^2 = 0\%$, RR $= 0.31$, 95% CI $[0.12, 0.81]$, $p = 0.02$) (Figure 12A). However, the course of 2–5 weeks ($n = 160$, $I^2 = 0\%$, RR $= 1.00$, 95% CI $[0.21, 4.82]$, $p = 1.00$) (Figure 12A) did not show statistical significance.

### Symptoms integral

The TCM symptoms integral mainly includes the total symptom score, individual symptom scores such as abdominal pain, diarrhea, urgency, pus and blood stool, and burning pain in the anus. The total symptom score mainly observes symptoms such as diarrhea, abdominal pain, and pus and blood stool, from

mild to severe, and scores 0, 1, 2, and 3, respectively. The higher the score, the more serious the symptoms. Three studies evaluated the total symptom score. The random-effect Meta-analysis suggested that the difference between the two groups was statistically significant (n = 257, I² = 55%; MD = -3.40; 95% CI [-4.02, -2.78], p < 0.00001) (Figure 12B). The sensitivity analysis showed that the study reported by Zhang G.R was the source of heterogeneity because excluding this study resulted in an I² = 0%.

Furthermore, the investigation also evaluated the individual symptom scores of abdominal pain, diarrhea, urgency, pus and blood stool, and burning anal pain. Although the heterogeneity was high, it indicated that rhubarb-based therapy could improve UC symptoms to some extent (Supplementary Figures S2, S3).

Publication bias

Publication bias was assessed by funnel plots for the included 29 studies which reported the primary outcome. The funnel plots were asymmetrical, suggesting a possible publication bias (Supplementary Figure S4).

Discussion

UC is one of the modern intractable diseases regarded by the World Health Organization (Pedersen et al., 2014). Longstanding UC bears a high risk of developing colitis-associated colon cancer (Ekbom et al., 1990). Recently, 5-ASA is the most widely used first-line drug which is obviously beneficial to mild to moderate UC but limited for severe UC (Ko et al., 2019). As the supplementary drugs, corticosteroids and immunosuppressive drugs often required by the severe patients. However, the long-term application of corticosteroids and immunosuppressive drugs always brings about significant side effects (Ko et al., 2019; Kobayashi et al., 2020). What’s more, surgery, as an optional therapy for sever UC, is mentioned to delay the progression of the disease, but the prognosis of surgery still carries the risk of colon cancer (Windsor et al., 2013). Basically, TCM has attracted increasing attention for the potential effective and safe treatment.

TFTM is a typical therapeutic method in TCM. According to TCM theory, TFTM mainly refers to those medicinals with purgative method. There are many representative medicinals of TFTM, such as Citrus × aurantium L. [Rutaceae; Citrus × aurantium young fruit], Magnolia officinalis Rehder & E.H.Wilson [Magnoliaceae; Magnolia officinalis bark], Aloe vera (L.) Burm.f. [Asphodelaceae; Aloe vera sap], Cannabis sativa L. [Cannabaceae; Cannabis sativa ripe fruit], which have been shown to treat experimental UC mainly by anti-inflammatory and modulating intestinal flora (He et al., 2018; Naini et al., 2021; Eom et al., 2022; Xie et al., 2022). But compared with those medicinals, rhubarb is the most representative, and it is also the most widely used in the treatment of gastrointestinal diseases (Zhang et al., 2021). Rhubarb has been validated to treat UC through immunsuppression, anti-inflammation, intestinal
flora regulation, and endotoxin inhibition (Miao et al., 2018; Xiang et al., 2020). The potential clinical value is necessary to be assessed with evidence-based methods.

In this study, 30 RCTs involving 2,421 patients were included in the Meta-analysis. The results reveal that the clinical efficacy of the rhubarb-based treatment group was significantly higher than that of the control group. Furthermore, a comparable number of RCTs evaluated the use of rhubarb-based medicinal formulas alone, supporting its effectiveness explicitly. 5-ASA and SASP belong to the 5-ASA class of medications, both of whom are the mainstay of treatment of mild to moderate UC (Ko et al., 2019). Long-term use of 5-ASA reduces the risk of relapse and cancer in UC patients, making it an indispensable drug for UC treatment (Kim, 2018; Wang et al., 2018). Nevertheless, for patients with severe UC, the therapeutic effect of 5-ASA is limited. Of note, the rhubarb-based medicinal formulas combined with 5-ASA or SASP were more effective than the use of 5-ASA or SASP alone, indicating that the synergistic effect of rhubarb is remarkable. The result suggests that rhubarb-based therapy might benefit patients who did not respond or could not tolerate 5-ASA treatment, thus avoiding the apparent side effects associated with the use of corticosteroid and thiopurine.

Further, patients with proctitis are always treated with 5-ASA suppositories, which target the site of inflammation directly and seem to be more effective than oral 5-ASA. In left-sided colitis, 5-ASA should be administered as an enema instead of a suppository in order to reach the splenic flexure (Gionchetti et al., 1998; Choi et al., 2015; Reinisch et al., 2015). As with 5-ASA, different administration routes of medicinals can directly

*Li et al. 10.3389/fphar.2022.1036593*
impact the efficiency rate. This study found that the rhubarb-based therapy was clinically more effective when administered either orally or by enema. What’s more, it was meaningful to add it to any course of treatment.

The symptoms of UC mainly include abdominal pain, vomiting, diarrhea, and rectal bleeding, which seriously affect life quality of patients. Studies have shown that rhubarb could exert various pharmacological effects in the gastrointestinal tract (Xiang et al., 2020). The combination of anthraquinones in rhubarb played a role in inducing diarrhea, while tannic acid could inhibit the purgative effect of anthraquinones and thereby induced anti-diarrheal effects (Qin et al., 2011; Cao et al., 2017). Through the review of TCM symptoms integral, it was found that rhubarb-based therapy could significantly improve the symptoms of abdominal pain, diarrhea, urgency, pus and blood stool, and burning anal pain in UC patients, and ultimately had a positive impact on the symptomology and quality of life of patients. Also, Mayo and Geboes scores revealed that the rhubarb-based therapy effectively improved the disease activity and the histological status of UC. And the result of the recurrence rate indicated that the disease process was effectively controlled and recurrence was delayed.

The hypercoagulable state is an essential part of the pathological mechanism of UC (Danese et al., 2007). Meanwhile, cytokines regulated by multiple inflammatory signaling pathways are a central component of chronic inflammation (Ungaro et al., 2017; Kobayashi et al., 2020). The imbalance of cytokines have been reported in patients with active IBD, including TNF-α, IL-1β, IL-6, IL-8, IL-10, IL-12, IL-17, IL-23, and TGF-β (Neurath, 2014). The simultaneous activation of coagulation and inflammation in colon injury foci are identified as the preservation mechanisms for repairing damaged areas (Lipinski et al., 2011). At the same time, the crosstalk between coagulation and inflammation has raised concerns. Inflammatory stimuli can trigger the coagulation cascade while coagulation also regulates inflammatory signaling pathways (de Maat et al., 2014). PLT, a principal coagulation marker, constitutes a crucial link between inflammation and coagulation, creating a vicious circle in which participating parameters conserve and propagate each other (Yoshida and Granger, 2009). PLT is activated at inflammatory sites and excrete large amounts of pro-inflammatory substances located in its intracellular granules (Smyth et al., 2009). The results of this Meta-analysis showed that rhubarb-based therapy significantly reduced PLT, TNF-α, IL-1β, IL-6, IL-1β, and CRP, and increased IL-10, as well as had some effects on PT and FIB. Thus, rhubarb-based therapy can improve the hypercoagulable state of UC and suppress intestinal inflammation. An important point to note was the highly heterogeneous results in the analysis of all six inflammatory cytokines, likely caused by the use of different measurement devices and measurement units in the original study. The results of this Meta-analysis should be interpreted with caution.

Moreover, rhubarb has a powerful blood-activating effect. It is a common medicinal for blood stasis syndrome (Liu et al., 2013; Gao et al., 2020). Studies have reported that rhubarb had significant anti-PLT effects and PLTs were the main effector cells of rhubarb in the promoting blood circulation to remove blood stasis method (Xu et al., 2012; Gao et al., 2020). It could significantly improve whole blood viscosity and plasma viscosity in high molecular dextran-induced hyperviscosity syndrome model in rats, and reduce the levels of PLT activation markers Plasma P-selectin and thromboxane (Gao et al., 2020). Additionally, rhubarb significantly affected local microcirculation, reducing local pancreatic blood flow in the pancreas and improving pancreatic microcirculation (Zhao et al., 2004). It protected the intestinal mucosal capillary endothelial cells and increased the number of functional capillaries, promoted blood flow throughintestinal mucosal capillaries, reduced thrombogenesis, and improved the blood and oxygen supply of the intestinal mucosa (Cui et al., 2014; Cui et al., 2016). Derivatives of rhubarb also had anti-PLT aggregation effects, among which, chrysophanol-8-O-glucoside, an anthraquinone derivative isolated from rhubarb, was found to have the most potent inhibitory effect on collagen- and thrombin-induced PLT aggregation and was mightier than the positive drug aspirin. Specifically, it was found to inhibit PLT aggregation in vitro and ex vivo and prolong bleeding time and activate partial thromboplastin time (Seo et al., 2012). In addition, the mixture of five monomeric compounds of rhubarb could antagonize the matrix Metalloproteinase-9-induced human umbilical vein endothelial cell (HUVEC) monolayer permeability by promoting HUVEC proliferation and reducing extracellular vascular endothelial-cadherin concentrations (Cui et al., 2016). In addition, although the bioavailability of rhubarb and its monomers may be low, it seems that we can consider combining them with nanosystems (Zhang et al., 2022a; Zhang et al., 2022b). In conclusion, based on the characteristics of coagulation abnormalities associated with UC and the exact clinical efficacy and experimental evidence of rhubarb in UC, the rhubarb’s coagulation-regulation effect is worthy of further investigation.

The incidence of adverse events is an important indicator to evaluate the safety of a treatment strategy. Several studies have reported that 5-ASA and SASP may cause adverse events such as fever, nausea, dizziness, and diarrhea (Schgal et al., 2018). In five of the six studies that reported adverse events, the control drug was 5-ASA class. Although a number of studies have reported that medicinals could reduce the incidence of adverse time when used in combination with 5-ASA (Chen et al., 2020), the results showed that rhubarb-based therapy did not significantly improve these side effects. For the subgroup analysis, the incidence of side effects was not statistically different at 2–5 weeks of treatment while showed a significant difference at 6–9 weeks. In addition, although rhubarb has the side effect of purgative, the results of our analysis showed that...
Rhubarb-based therapy did not exhibit significant side effects. This means it has a high safety profile in clinical use. This article concludes that the rhubarb-based therapy can improve clinical efficacy, improve clinical symptoms, and reduce recurrence rate in UC. It can also ameliorate the hypercoagulable and inflammatory status. In addition, subgroup analysis suggests that early intervention of rhubarb-based therapy will obtain better effects. There is a synergistic effect of the rhubarb-based medicinal formulas with 5-ASA or SASP. Nevertheless, the mechanism of the synergistic effect has not been revealed completely that require more investigations.

To determine the characteristics and patterns of specific medicinals used in the rhubarb-based medicinal formulas, this investigation analyzed the medicinals used in each original study (Supplementary Figure S5). The high-frequency medicinals (frequency ≥14) were rhubarb, Glycyrrhiza glabra L. [gān cǎo; Fabaceae; Glycyrrhiza glabra root and rhizome], Coptis chinensis Franch. [huáng lián; Ranunculaceae; Coptis chinensis rhizome], Scutellaria baicalensis Georgi [huáng qín; Lamiaceae; Scutellaria baicalensis root], Angelica sinensis(Oliv.)Diels [dāng guì; Apiaceae; Angelica sinensis root], Paeonia lactiflora Pall. [bái sháo; Paeoniaceae; Paeonia lactiflora root], and Dolomiaea costus
medicinal formulas, which raises an optional protocol for UC decoction strategy for the clinical application of rhubarb-based rhubarb in the TCM industry. This makes them not the related to UC, and their recognition is not as widely used in clinical practice, but there are few studies addition, the other representative medicinals of TFTM are the rational application of rhubarb-based therapy for UC. In clinic. According to the TCM, UC, or other dysfunctions of the gastrointestinal tract in the treat patients with chronic gastritis, peptic ulcer, acute dysentery, (Han et al., 2013). The pattern analysis provides a more precise inflammation damage in UC rats by reducing the level of MPO and the expression of TNF-α and NF-κB, and increasing the production of IL-10 in colon tissues (Han et al., 2013). The pattern analysis provides a more precise decoction strategy for the clinical application of rhubarb-based medicinal formulas, which raises an optional protocol for UC patients.

Limitation

As the available studies only provided short-term assessments of 2–13 weeks, this investigation is not able to assess the long-term efficacy and safety of the rhubarb-based therapy for UC. Second, the lack of a large number of high-quality, multicenter standard RCTs and the lack of description of random assignment procedures and blinding in some studies may also affect the quality of this Meta-analysis. Furthermore, even though this paper used sensitivity analysis to reduce the effect of different measurement units and methods on the results, the outcomes of inflammatory cytokines, and TCM symptoms integral to this Meta-analysis still showed a high level of heterogeneity. Hence, the results of the analysis should be identified carefully. It would be beneficial if more research would be conducted to promote the rational application of rhubarb-based therapy for UC. In addition, the other representative medicinals of TFTM are widely used in clinical practice, but there are few studies related to UC, and their recognition is not as high as rhubarb in the TCM industry. This makes them not the object of our Meta-analysis. But their value also deserves more exploration in the future.

Conclusion

In this article, rhubarb-based therapy is effective in improving UC, especially in terms of relieving clinical symptoms, reducing recurrences, and improving hypercoagulable states and inflammation. Furthermore, the rhubarb-based medicinal formulas combined with 5-ASA or SASP are more effective than 5-ASA or SASP alone. And rhubarb-based therapy is recommend use within 1–3 weeks or 3 months via administered orally or by enema, which is contributes to ensure the curative effect and avoid its side effects. As an important case of TFTM, rhubarb-based therapy provides evidence for the practical application of TFTM, and also provides ideas for further development and exploration.

Data availability statement

The original contributions presented in the study are included in the article/Supplementary Material, further inquiries can be directed to the corresponding authors.

Author contributions

YL and ZY contributed to the conception and design of the study. ZY, YH, and HH searched the database separately. MW, YL, QZ, and CZ performed the studies selection separately. LC, YL, LL, QS, and HH carried out the statistical analysis. YL, ZY, and HQ wrote the first draft of the manuscript. QY, KQ, YH, and XL were responsible for technical guidance and quality control of the manuscript. All authors contributed to manuscript revision, read, and approved the submitted version. All divergences were resolved through discussion among all authors.

Funding

This research was funded by the National Natural Science Foundation of China (81973742) and National Traditional Chinese Medicine Characteristic Technology Inheritance Talent Training Project ((2019) No. 43).

Acknowledgments

The authors would like to express their sincere thanks to all the people who participated in the research and partner units.
Conflict of interest

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.
