Abstract—We consider the problem of characterizing network capacity in the presence of adversarial errors on network links, focusing in particular on the effect of low-capacity feedback links across network cuts. In [1], the authors gave cut-set bound for unequal links capacity network and achievable strategy for coding, decoding and detection, which only cover the network with large enough feedback across the network, allowing intermediate nodes reliably transporting part of code by some proper code back to upper source. However when feedback has small capacity, the strategy will be failed, the intuition is that you cannot have a simple code on low capacity feedback. We analysis thoroughly the behavior of adversary on small capacity of feedback link, which turns out that it’s more complex than large-capacity feedback, and give corresponding strategies. We give a new outer bound as well as a new achievable strategy, and show a family of networks where the inner and outer bounds coincide.

I. INTRODUCTION

The problem of reliable network communication in the presence of adversarial link errors was first considered by Yeung and Cai [2], [3] for the case of networks with equal capacity links. They generalized the Hamming bound, the Singleton bound, and the Gilbert-Varshamov bound from classical error correction coding to network coding. In this problem, an adversary can arbitrarily corrupt information on a set of links of capacity one without loss of generality, but in the case of errors, there is a loss of generality in assuming that errors occur independently on the unit capacity edges.

In recent work [1], [4], [5], the authors considered the case of networks with unequal link capacities. They showed that, unlike the case of equal link capacities, feedback across network cuts can increase the error correction capacity. They provided upper bounds on capacity, and coding strategies that achieve the upper bounds in a family of zig-zag networks with feedback links of sufficient capacity.

We introduce a new upper bounding approach which considers confusion between two possible sets of z forward adversarial links, when there exist two codewords that differ on network cuts. In [1], the authors gave cut-set bound for unequal links capacity network and achievable strategy for coding, decoding and detection, which only cover the network with large enough feedback across the network, allowing intermediate nodes reliably transporting part of code by some proper code back to upper source. However when feedback has small capacity, the strategy will be failed, the intuition is that you cannot have a simple code on low capacity feedback. We analysis thoroughly the behavior of adversary on small capacity of feedback link, which turns out that it’s more complex than large-capacity feedback, and give corresponding strategies. We give a new outer bound as well as a new achievable strategy, and show a family of networks where the inner and outer bounds coincide.

II. PRELIMINARY

We consider a communication network represented by a directed acyclic graph \( G = (V, E) \). Source node \( s \in V \) transmits information to the sink nodes \( u \in V \). Let \( r(a, b) \) denote the capacity of edge \((a, b) \in E \). We assume that code alphabet \( \mathcal{A} \) is \( GF(q) \) for some large enough \( q \). We can view an error vector on a link \( l \in E \) as set of \( r(l) \) symbols in \( \mathcal{A} \), where the output \( y_1 \) of link \( l \) equals the mod \( q \) sum of the input \( x_1 \) to link \( l \) and the error \( e_l \) applied to link \( l \). We say that there are \( \tau \) error links in the network if \( e_l \neq 0 \) on \( \tau \) links.

**Definition 1.** A network code is \( z \)-error link-correcting if it can correct any \( \tau \) adversarial links for \( \tau \leq z \). That is, if the total number of adversarial links in the network is at most \( z \), then the source message can be recovered by all the sink nodes \( u \in U \).

Let \( (A, B) \) be a partition of \( V \), and define the cut for the partition \((A, B)\) by

\[
\text{cut}(A, B) = \{(a, b) \in E : a \in A, b \in B\}.
\]

\(\text{cut}(A, B)\) is called a cut between two nodes \( a \) and \( b \) if \( a \in A \) and \( b \in B \). The links in \( \text{cut}(A, B) \) are called the forward links of the cut. The links \((a, b)\) for which \( a \in B, b \in A \) are called the feedback links of the \( \text{cut}(A, B) \). The capacity of a cut is the sum of the capacities of the forward links of the cut.

For any cut \( Q = \text{cut}(P, V \setminus P) \), let \( Q^R \) denote the set of feedback links across cut \( Q \). We say that a feedback link \( l \in Q^R \) is directly downstream of a forward link \( l' \in Q \) (and that \( l' \) is directly upstream of \( l \)) if there is a directed path starting from \( l' \) and ending with \( l \) that does not include other links in \( Q \) or \( Q^R \).

III. NEW UPPER BOUND

We introduce a new upper bounding approach which considers confusion between two possible sets of \( z \) forward adversarial links, when there exist two codewords that differ in these forward links but coincide in the values of their directly downstream feedback links and the remaining forward links. The bound is then the sum of the capacities of these feedback links plus the capacities of the remaining forward links.
links. Therefore, this bound is useful when the feedback link capacities are sufficiently small.

To state this result formally, consider any cut \( Q = \text{cut}(P, V \setminus P) \), and two disjoint sets of forward links \( Z_1, Z_2 \subset Q \) where \( |Z_i| \leq z \) for \( i = 1, 2 \). Let \( W_1 \) be the set of links in \( Q^R \) which are directly downstream of a link in \( Z_1 \) and upstream of any link in \( Q \setminus Z_1 \). Let \( W_2 \) be the set of links in \( Q^R \) which are directly downstream of a link in \( Z_2 \) and upstream of a link in \( Q \setminus Z_2 \).

**Theorem 1.** Let
\[
M = \sum_{(a,b) \in (Q \setminus Z_1) \cup W_1 \cup W_2} r(a, b)
\]
denote the sum of capacities of forward links in \( (Q \setminus Z_1) \setminus Z_2 \) and feedback links in \( W_1 \) and \( W_2 \). If no link in \( Z_2 \) is directly upstream of any link in \( W_1 \), and no link in \( Z_1 \) is directly upstream of any link in \( W_2 \), then the capacity is at most \( M \).

**Proof:** We assume that the codebook \( X \) contains more than \( q^M \) codewords, and show that this leads to a contradiction. Let \( k \) denote the number of links on the cut \( Q \), and let \( m = |Z_1|, n = |Z_2| \).

Since \( |X| > q^M \), from the definition of \( M \), there exist two distinct codewords \( x, x' \in X \) such that the error-free outputs on the links in \( (Q \setminus Z_1) \setminus Z_2 \) and \( W_1 \cup W_2 \) are the same. The corresponding observations on the sink side of the cut are
\[
O(x) = \{y_1, \ldots, y_k - m - n, u_1, \ldots, u_m, \underbrace{w_1, \ldots, w_n}_1\}
\]
\[
O(x') = \{y_1, \ldots, y_k - m - n, u_1', \ldots, u_m', \underbrace{w_1', \ldots, w_n'}_1\},
\]
where \( \{y_1, \ldots, y_k - m - n\} \) denote the error-free outputs on the links in \( (Q \setminus Z_1) \setminus Z_2 \) for \( x \) and \( x' \); \( \{u_1, \ldots, u_m\} \) and \( \{u_1', \ldots, u_m'\} \) denote the error-free outputs on the links in \( Z_1 \) for \( x \) and \( x' \) respectively; and \( \{w_1, \ldots, w_n\} \) and \( \{w_1', \ldots, w_n'\} \) denote the error-free outputs on the links in \( Z_2 \) for \( x \) and \( x' \) respectively.

Since no link in \( Z_2 \) is directly upstream of any link in \( W_1 \), the values on \( W_1 \) are determined by the values on \( Q \setminus Z_2 \). Similarly, since no link in \( Z_1 \) is directly upstream of any link in \( W_2 \), the values on \( W_2 \) are determined by \( Q \setminus Z_1 \).

We will show that it is possible for the adversary to produce exactly the same outputs on all the channels in \( Q \) under \( x \) and \( x' \) when errors occur on at most \( z \) links.

Assume the input of network is \( x \). The adversary could choose forward links set \( Z_1 \) as its \( z \) adversarial links, and apply errors on \( Z_1 \) to change the output from \( u \) to \( u' \) \( \forall 1 \leq i \leq m \). Note that the values on \( W_1 \) are determined by the values on \( Q \setminus Z_2 \), which, under these errors, are same as for \( x' \), and that the values on \( W_1 \) are the same for \( x \) and \( x' \). Therefore, the values on \( W_1 \) are not changed, and thus the values on \( Q \setminus Z_1 \) are not affected. The observations on the sink side of the cut are \( \{y_1, \ldots, y_k - m - n, u_1', \ldots, u_m', w_1, \ldots, w_n\} \).

When codeword \( x' \) is transmitted, the adversary could choose forward links set \( Z_2 \) as its \( z \) adversarial links, and apply errors on them to change \( (w_1', \ldots, w_n') \) to \( (w_1, \ldots, w_n) \). Similarly, since the values on \( W_2 \) are determined by the values on \( Q \setminus Z_1 \), which, under these errors, are the same as for \( x \), and since the values on \( W_1 \) are the same for \( x \) and \( x' \), the values on \( W_2 \) and on \( Q \setminus Z_2 \) are not affected. The observations on the sink side of the cut are \( \{y_1, \ldots, y_k - m - n, u_1', \ldots, u_m', w_1, \ldots, w_n\} \).

A number of variations of this result are possible. For instance, if there are no links in \( Q^R \) which are directly downstream of a link in \( Z_2 \) and upstream of a link in \( Q \setminus Z_2 \) (i.e., \( W_2 \) is empty), we can redefine \( W_1 \) to be the set of links in \( Q^R \) which are directly downstream of a link in \( Z_1 \) and upstream of a link in \( (Q \setminus Z_1) \setminus Z_2 \), which is smaller compared to the previous definition.

For the example network in Fig. 1 with two adversarial links, our previous result in (1) gives a bound of 8, whereas Theorem 1 gives a bound of \( 5 + b \), which is tighter when \( b < 3 \).

![Fig. 1. Four node acyclic networks:](image)

**IV. PRELIMINARY FOR ACHIEVE STRATEGY**

![Fig. 2. Four nodes acyclic network:](image)
be the number of links from node B to the sink. We will call upstream for links between source and node A, downstream for links between intermediate node B and sink.

By Theorem 1, we focus on the family of zig-zag network, the upper bound of which is

\[ UB = (n - z)a + (m - z)c + b \]

According to [1], the tight bound of zig-zag network is strongly related with topology of network, in order to provide a proper coding strategy, we have to first discuss properties of topology of network.

To find these conditions, we compare UB with cut set bound considered in [1]. Strictly, there are three variations of cut set bound according to topology of network in [1]. We describe these possible bounds briefly as following:

1) **SB1**: Adversary attacks z₁ downstream links and no more than 2z₂ - z₁ other downstream links on two codewords respectively, which they implicate each other.

2) **SB2**: Adversary erases feedback link and we bound the remaining network by Singleton bound.

3) **SB3**: Adversary attacks feedback link and z₁ upstream links implicating z₂ attack on downstream, and attacks z₂ on downstream links implicating z₁ attack on downstream and feedback, \( z₁ + z₂ \leq 2z - 1 \).

4) **SB₄(UB)**: Adversary attacks z₁ upstream links and z₂ downstream links to implicate each other with the same output on feedback link, \( z₁ + z₂ \leq 2z \).

We categorize zig-zag network into four categories by observation of number of upstream and downstream.

**Category 1.** \( n \geq 2(z - 1), m \geq 2z \)

According to above describe about SB1 and SB2, we give

\[
SB1 = na + (m - 2z)c \\
SB2 = (n - 2(z - 1))a + mc
\]

Suppose UB is tighter than SB1 and SB2, then

\[
0 < SB1 - UB \\
0 < na + (m - 2z)c - ((n - z)a + (m - z)c + b) \\
b < z(a - c)
\]

and

\[
0 < SB2 - UB \\
0 < (n - 2(z - 1))a + mc - ((n - z)a + (m - z)c + b) \\
b < zc - (z - 2)a
\]

Thus we have,

\[
b < \min\{z(a - c), zc - (z - 2)a\} \quad (1)
\]

and new bound is tightest in network \( G \) under [1].

**Category 2.** \( z \leq n < 2(z - 1), m \geq 2z \)

We have

\[
SB1 = na + (m - 2z)c \\
SB2 = (m - 2z - n))c
\]

Since \( UB < SB1, UB < SB2 \), it’s not hard to have

\[
b < \min\{z(a - c), (n - z + 2)c - (n - z)a\} \quad (2)
\]

Clearly, [1] and [2] exactly define a family of networks in which new bound we proposed is tight.

For SB3, it is a trivial case that \( UB < SB \), since

\[
SB3 = (n - (z - 1))a + (m - z)c \\
= (n - z)a + (m - z)c + a
\]

where \( b < a \) by definition of four-node network.

**Category 3.** \( n \geq 2(z - 1), m < 2z \)

According to above describe on possible bounds, we have

\[
SB1 = (n - (2z - m))a \\
SB2 = (n - 2(z - 1))a + mc \\
= (n - z)a + (m - z)c + zc - (z - 2)a \\
SB3 = (n - (z - 1))a + (m - z)c \\
= (n - z)a + (m - z)c + a
\]

Suppose UB is tighter than above bounds, compare it with SB1, SB2, SB3, not hard to have the following inequalities,

\[
b < zc - (z - 2)a \\
b < (m - z)(a - c) \\
b < a
\]

which follows \( UB < SB1, UB < SB2, UB < SB3 \) respectively, thus we have

\[
b < \min\{zc - (z - 2)a, (m - z)(a - c)\} \quad (3)
\]

**Category 4.** \( z \leq n < 2(z - 1), m < 2z \)

Similarly, we have SB1, SB2, SB3,

\[
SB1 = (n - (2z - m))a \\
= (n - z)a + (m - z)c + (m - z)(a - c) \\
SB2 = (m - 2(z - 1) - n)c \\
= (n - z)a + (m - z)c + (n - z + 2)c - (n - z)a \\
SB3 = (n - (z - 1))a + (m - z)c \\
= (n - z)a + (m - z)c + a
\]

Suppose UB is tighter than the other bounds, we have the tight condition,

\[
b < (n - z + 2)c - (n - z)a \\
b < (m - z)(a - c) \\
b < a
\]

which gives

\[
b < \min\{(n - z + 2)c - (n - z)a, (m - z)(a - c)\} \quad (4)
\]

Note that in this paper, we will call [1]–[4] as tight conditions. We formalize the upper bound to be
V. ENCODE

Let \( \mathcal{X}, \mathcal{Y} \) be message set and \( k_1 = n - z, k_2 = \left\lceil \frac{b}{n-c} \right\rceil \),
\[
\mathcal{X} = \left\{ x_{i,j} \mid 1 \leq i \leq a-c, 1 \leq j \leq (n-z) + k_2 \right\}
\]
\[
\mathcal{Y} = \left\{ y_{i,j} \mid 1 \leq i \leq c, 1 \leq j \leq m + n - 2z \right\}
\]

Notice that for \( \mathcal{X} \), we define only when \( \frac{b}{n-c} \) is integer, otherwise equality holds for \( j \).

Each message symbol is i.i.d over GF(q) and \( q \) is a prime power. Let \( X \) be \((a-c) \times n\) matrix, \( i \)th row of which is defined as
\[
(x_{i,1}, x_{i,2}, \ldots, x_{i,k_1+k_2'}) G
\]
where \( x_{i,j} \in \mathcal{X} \) and \( \sum_{i=1}^{a-c} k_{i,2}' = b, 0 \leq k_{i,2}' \leq k_2 \)
\[
G = (I_{(k_1+k_2') \times (k_1+k_2')}, E)
\]
(5)
where \( G \) is generator matrix for a \((n, n-k_1-k_2')\) systematic MDS code, we denote entries of \( E \) by \( \eta_{i,j}, i = 1, \ldots, k_1 + k_2', j = 1, \ldots, n - k_1 - k_2' \) which are chosen uniformly at random from nonzero entries of a large finite field.

Not hard to check that we can choose \( k_{i,2}' \in [0, k_2] \) for each row of \( X \) properly to encode \( |\mathcal{X}| = UB - |\mathcal{Y}| \) message symbols.

Define \( Y \) is a \( c \times (n+m-2z) \) matrix, the \((i,j)\)th entry of matrix \( Y \) is given by \( y_{i,j} \in \mathcal{Y}, 1 \leq i \leq c, 1 \leq j \leq n+m-2z \), and define \( L \) is a \( c \times 22 \) matrix, the \((i,j)\)th entry of matrix \( L \) is denoted by \( l_{i,j}, 1 \leq i \leq c, 1 \leq j \leq 2z \), which is linear combination of all the message symbols \( \{X, Y\} \), in that any subset of symbols is maximally independent. Note that there is large enough \( q \) such that any subset of symbols in \( Y \) are maximally independent over \( GF(q) \).

On network \( G \), we define codeword for given message sequence \( (X, Y) \) as follows,
\[
C = \begin{pmatrix} X & 0 \\ Y & L \end{pmatrix}
\]
where \( 0 \) is zero matrix, the dimension of which is \((a-c) \times m\). Then the dimension of \( C \) is \( a \times (m+n) \). Source \( S \) and node \( B \) cooperate to send codeword \( C \). Source \( S \) sends the first columns \( i = 1, \ldots, n \) of \( C \) to \( A \) and node \( B \) sends the columns \( i = n+1, \ldots, n+m \) to sink.

If no errors have previously been detected, the signal sent by node \( A \) on the feedback link is defined as follows. Consider arbitrary row of \( X \), we rewrite the row vector as following for easily analysis, and we ignore the index of row for simplicity.
\[
(x_{1,1}, x_{1,2}, \ldots, x_{1,k_1+k_2}, r_1, r_2, \ldots, r_n)
\]
\[
= (x_{1,1}, x_{1,2}, \ldots, x_{1,k_1+k_2'}, r_1, r_2, \ldots, r_n)
\]
where \( k_3 = n - k_1 - k_2' \) and let \( x = \{x_i = r_i, i = 1, \ldots, k_1\}, v = \{v_i = r_{k_1+i}, i = 1, \ldots, k_2'\}, r = \{r_i, i = 1, \ldots, n-k_1-k_2'\} \) where from (5), \( r_j = \sum_{i=1}^{k_1+k_2'} \eta_{i,j} x_i, j = 1, \ldots, n-k_1-k_2' \) and \( k_2' \) represents \( k_{i,2}' \), \( \eta_{i,j} \) represents the \((i,j)\) elements of \( E \).

Now consider a received row vector of \( \hat{X} \) at node \( A \),
\[
(\hat{x}_1 \ldots \hat{x}_{k_1}, \hat{v}_{k_1+1} \ldots \hat{v}_{k_1+k_2'}, \hat{r}_1 \ldots \hat{r}_{k_3}).
\]
(7)
where from (Node \( A \)) sends the feedback symbols
\[
\{\delta_i = \hat{v}_i - (\eta_{1,1}\hat{v}_1 + \ldots + \eta_{k_1,1}\hat{v}_{k_1}) | i = 1, \ldots, k_2'\}
\]
(8)
corresponding to each row of \( \hat{X} \).

Then we define claim message on node \( B \) which will be used when new erroneous is detected on upstream. Let claim message \( W \) be \((a-c) \times m \) matrix such that \((X, W)\) is an \((n+m, n+m-k_1-k_2)\) MDS code.

VI. ENCODING ERROR SIGNALING

We will describe strategy to show how intermediate node \( A \) and \( B \) cooperate to detect adversary on upstream in this section.

Strategy will show that either intermediate node \( A \) or \( B \) could find out when erroneous is injected first time on upstream, and Lemma [1] in following shows that if sink has identified two adversary links successfully on upstream, sink can decode without feedback and any extra information from intermediate nodes, thus we will focus on the following scenario of adversary behavior,

1) Adversary only attacks forward link in first attack.
2) Adversary attacks the other forward links to hide the changing of attack behavior in subsequent attack.

Lemma 1. Given two adversary links from source \( S \) to node \( A \) are identified, the sink can decode correctly with remaining codeword without information from feedback link.

Proof: Suppose the number of upstream links identified by sink is \( z \), denote Singleton bound on remaining network by \( SB \).

Category 1. \( n > 2(z-1) \)
Singleton bound, \( SB \), on the remaining network is
\[
SB = (n-x-2(z-x))a + mc
\]
(9)
\[
= (n+x-2z)a + mc
\]
Then define
\[
f(x) = SB - UB
\]
\[
= (n+x-2z)a + mc - ((n-z)a + (m-z)c + b)
\]
\[
= ax - z(a - c) - b
\]
Observe zero point of \( f(x) \), we have
\[
x = \frac{z(a - c) + b}{a} \leq \frac{z(a - c) + zc - (z-2)a}{a}
\]
(10)
where (10) follows (1), (9).

Then \( f(x) \) is a strictly monotonous increase function for given network.

Category 2. \( z \leq n \leq 2(z-1) \)

Consider the $SB$ on remaining network,

$$SB = \begin{cases} (n + x - 2z)a + mc & x > 2z - n \\ (n + m + x - 2z)c & x \leq 2z - n \end{cases}$$

Then we have $f(x)$ denoted as

$$f(x) = SB - UB = \begin{cases} ax - z(a - c) - b & x > 2z - n \\ xc - (n - z)(a - c) - b & x \leq 2z - n \end{cases}$$

Consider zero point of $f(x)$ when $x \leq 2z - n$,

$$\begin{align} 0 &= f(x) \\ 0 &= xc - (n - z)(a - c) - b \\ x &= \frac{(n - z)(a - c) + b}{c} \\ &< \frac{(n - z)(a - c) + (n - z + 2)c - (n - z)a}{c} \quad (12) \\ &= 2 \quad (13) \end{align}$$

where (13) follows (2), (3). Clearly, $f(x)$ is a strictly monotonous increase function when $x \leq 2z - n$. Then we observe $f(x)$ for $x > 2z - n$,

$$\begin{align} f(x) &= ax - z(a - c) - b \\ &= ax - z(a - c) - ((n - z + 2)c - (n - z)a) \\ &> ax - z(a - c) - (zc - (n - z)a) \quad (14) \\ &= (x - 2z + n)a \\ &> 0 \quad (15) \end{align}$$

Then $f(x)$ is a strictly monotonous increase function and it has an unique zero point $x = 2$. Thus we have $f(x) = SB - UB > 0$ when $x = 2$, which indicates that Singleton bound on the remaining network is greater than $UB$ on the original network after the sink identifies 2 adversary links between source node and node $A$.

A. Preliminary for error signaling

For each codeword $C$, intermediate node $A$ receives $\hat{X}$ and $\hat{Y}$. Node $A$ checks each row of $\hat{X}$, then according to results of observation, it will send side information to node $B$, which lets node $B$ have some knowledge of upstream.

Before error signaling description, we give some preliminary first and we assume that feedback link is clean in section VII. Consider a row vector of $\hat{X}$ at node $A$ by ignoring index of row,

$$(\hat{x}_1 \ldots \hat{x}_{k_1}, \hat{v}_1 \ldots \hat{v}_{k_2}, \hat{r}_1 \ldots \hat{r}_{k_3})$$

We define $\Delta$ for each received row vector,

$$\Delta = \{\delta_j = \hat{r}_j - \sum_{i=1}^{k_1} \eta_{i,j}\hat{x}_i - \sum_{i=k_1+1}^{k_1+k_2} \eta_{i,j}\hat{v}_i\} \quad (16)$$

where $j = 1, \ldots, k_3$.

The intuition of detection is that intermediate node $A$ and $B$ choose proper strategy by observing variation of $\Delta$ to detect new happened adversary links.

Define claim-sending signal from node $A$, calling it $CS$, for short, once node $B$ receives $CS$, it will sends $W$ to sink, it will let sink have $(\hat{X}, \hat{W})$, which is an MDS code against at most $z$ error links.

B. Error Signal Encoding Analysis

In this subsection, we will discuss several cases to show that there is always a proper strategy for intermediate node $A$ and $B$ such that:

- Once adversary conduct the first attack on $X$, either node $A$ or node $B$ has ability to find it.
- Adversary cannot hide the new error links by corrupt multi-links given there was only one link attacked in previous transmission.

We simply describe feedback operation for error signal first. For each received row of $\hat{X}$, node $A$ observes $\Delta$, since $\delta_i \in \Delta$ is derived from redundant symbol on corresponding row of $\hat{X}$, it can reflect whether $(x, r)$ is attacked, then based on observation of $\Delta$, node $A$ will send different error signal messages through feedback.

Also the signals on feedback could be different even for the same observation of $\Delta$ since the same observations of $\Delta$ from different transmission could be caused by different adversary behaviors. Thus error signal on feedback that node $A$ sends is formulated by considering the observation of previous $\Delta$ too.

And we define a general operation function on feedback,

$$F = \{\tilde{f} = H(\delta_i, i = 1, \ldots, k_2)\}, \quad (17)$$

where $H(\cdot)$ is a linear function determined by the observation of $\Delta$.

We organize error signaling analysis according to size of $\Delta$ since different size of $\Delta$ indicates different detection ability on node $A$, and the strategy used by node $A$ to cooperate with node $B$ have to be different.

Recall definition of $\Delta$, the size of $\Delta$ on each row of $X$ is determined by $k_2'$. Since $k_2 = \lceil \frac{b}{\frac{b}{2n - z}} \rceil$ and $b < z(a - c)$, we have $k_2 \leq z$, which says $0 \leq k_2' \leq z$. Given an $X$, different rows can has different size of $\Delta$, which are

1) $|\Delta| = z$ with $k_2' = 0$
2) $2 \leq |\Delta| < z$ with $0 < k_2' \leq z - 2$
3) $|\Delta| = 0$ with $k_2' = z$
4) $|\Delta| = 1$ with $k_2' = z - 1$

We will discuss them in four cases, in each of which we focus on node $A$ and node $B$ cooperates when erroneous happened first time and node $A$ and node $B$’s behavior when new attack happens in subsequent transmission.

Case-I: $|\Delta| = z, k_2' = 0$

By the condition, the row has structure as

$$(x_1, \ldots, x_{k_1}, r_1, \ldots, r_z) \quad (18)$$

where $x_i \in \mathcal{X}, i = 1, \ldots, k_1$ and $r_j = \sum_{i=1}^{k_1} \eta_{i,j}x_i, j = 1, \ldots, z$. 
Given a received \[\hat{r}_j\], we have
\[
\Delta = \{ \delta_j = \hat{r}_j - \sum_{i=1}^{k_1} \eta_{i,j} \hat{x}_i | j = 1, \ldots, z \}
\]
and \[\hat{r}_j = \sum_{i=1}^{k_1} \eta_{i,j} x_i + \Delta r_j\] where \(x_i\) is clean symbol and \(\Delta r_j\) is injected error symbol, let \(\Delta x_i = x_i - \hat{x}_i\), we have
\[
\Delta = \{ \delta_j = \sum_{i=1}^{k_1} \eta_{i,j} \Delta x_i + \Delta r_j, j = 1, \ldots, z \} \quad (19)
\]
Let \(e\) be number of happened error links, then we consider:
Case-1-1: \(e = 1\) in first attack.
There are two choices for adversary to conduct the corruption.
1.1) Attack one of \(x_i, i = 1, \ldots, k_1\).
1.2) Attack one of \(r_j, j = 1, \ldots, z\).
For (1.1), node \(A\) observes all \(\delta_j \neq 0\) of \(\Delta\) and not hard to see that it can identify the attacked link.
For (1.2), node \(A\) observes single \(\delta_i \neq 0\) of \(\Delta\), and the other \(\delta_j\) in \(\Delta\) equals to zero.
Both of these observation happened in first time, node \(A\) sends \(CS\) signal to node \(B\), which triggers node \(B\) sending \(W\) to sink.
Case-1-2: \(e \geq 2\) in subsequent attack.
We show node \(A\) can detect if there is new error link happened by observe \(\Delta\) or a variation of \(\Delta\). In subsequent attack, in order to avoid detecting by node \(A\), adversary should create the same observation of \(\Delta\) for node \(A\) by attacking new links.
For (1.1) happened in first attack, we give,
\[\textbf{Claim 1.} \text{Given single} \; \hat{x}_i, i \in [1, k_1] \; \text{is attacked in first attack, adversary cannot hide new error link in next attack.} \]
\[\textbf{Proof:} \text{Assume adversary attacks new links in} \; X \; \text{in next attack, node} \; A \; \text{observes the following equations}
\]
\[
\delta_j - \frac{\eta_{i,j}}{\eta_{i,1}} \delta_1 = \sum_{g=1}^{k_1} \eta_{g,j} \Delta x_g + \Delta r_j - \frac{\eta_{i,j}}{\eta_{i,1}} \left( \sum_{g=1}^{k_1} \eta_{g,1} \Delta x_g + \Delta r_1 \right)
\]
\[
= \sum_{g=1}^{k_1} \left( \eta_{g,j} - \frac{\eta_{i,j}}{\eta_{i,1}} \right) \Delta x_g + \Delta r_j - \frac{\eta_{i,j}}{\eta_{i,1}} \Delta r_1 \quad (20)
\]
In (20), the term \(\Delta x_i\) is canceled (\(\Delta x_i\) is on the previous identified link). Except \(\Delta x_i\), there are at most \(z - 1\) non-zero injected error terms including \(\Delta x_j, \Delta r_j\). Note that we have \(z - 1\) equations, by property of linear there must be at least one non-zero equation if new error link happened.
For (1.2) happened in first time, node \(A\) observed one \(\delta_j \neq 0\) and all the other \(\delta_i = 0\) in \(\Delta\). In subsequent attack, adversary has \(z - 1\) extra ability to corrupt new links, adversary has two possible attack behavior:
1) Only attack new single link, i.e., attack either one of \(x\) or \(r_j, l \in [1, z]\) such that \(\delta_l \neq 0, l \neq j\).
2) Attack multi links.
Consider only new single error link happened. If it’s happened on one of \(x_i, i = 1, \ldots, k_1\), it will cause all \(\delta_i \neq 0\) in \(\Delta\), which will let node \(A\) know there’s new error link happened. If adversary only attacks one of \(r_j, l \neq j\), node \(A\) will observe \(\delta_l \neq 0\) and the other \(\delta_j = 0\) in \(\Delta\), which can trigger node \(A\) sending \(CS\).
Consider multi error links in next attack. If error only injected in \(r\), then node \(A\) will observe more than one non-zero \(\delta_j\) of \(\Delta\); if there is error on \(x\), assuming \(\hat{x}\) errors happened on \(x_i, i = 1, \ldots, k_1\), in order to keep \((z - 1) \; \delta_i = 0, i \neq j\), adversary needs to attack \(z\) extra links since the property of MDS code, however adversary only has \(z - 1 - \hat{z}\) extra ability, it indicates that if any new error link happened, node \(A\) will observe more than one \(\delta_j \neq 0\) in \(\Delta\). And it means that adversary cannot hide multi-error in next attack, i.e., adversary cannot attack multi links such that only \(\delta_j \neq 0\) and all the other \(\delta_i = 0\) in \(\Delta\).
\[\textbf{Case-2:} 2 \leq |\Delta| < z, 0 < k_2 \leq z - 2 \]
By condition, the row has structure
\[
(x_1, \ldots, x_{k_1}, v_1, \ldots, v_{k_2}, r_1, \ldots, r_{k_3}) \quad (21)
\]
where \(2 \leq k_3 \leq z\). Given a received \(\{\hat{x}\}\), we have
\[
\Delta = \{ \delta_j = \hat{r}_j - \sum_{i=1}^{k_1} \eta_{i,j} \hat{x}_i - \sum_{i=k_1+1}^{k_1+k_2} \eta_{i,j} \hat{v}_i | j = 1, \ldots, k_3 \}
\]
where for \(j = 1, \ldots, k_3\),
\[
\delta_j = r_j + \Delta r_j - \left( \sum_{i=1}^{k_1} \eta_{i,j} \hat{x}_i + \sum_{i=k_1+1}^{k_1+k_2} \eta_{i,j} \hat{v}_i \right) = \sum_{i=1}^{k_1+k_2} \eta_{i,j} \Delta x_i + \Delta r_j \quad (22)
\]
where \(\Delta x_i = x_i - \hat{x}_i\) and \(\Delta x_i, \Delta r_i\) are injected error symbol.
First we show node adversary cannot hide erroneous on both of node \(A\) and \(B\) at the same time, which implies that once error happened first time either node \(A\) or node \(B\) can detect it.
Assume upstream link/links was/were attacked, the only way to avoid detection on node \(A\) is given observation of all \(\delta_j = 0 \in \Delta\), which is
\[
\sum_{i=1}^{k_1+k_2} \eta_{i,j} \Delta x_i + \Delta r_j = 0, j = 1, \ldots, k_3
\]
Without error detection, node \(A\) sends set \(F\) to node \(B\), where
\[
F = \{ f_j = \hat{v}_j + \sum_{i=1}^{k_1} \theta_{i,j} \hat{x}_i | j = 1, \ldots, k_2 \}
\]
When node $B$ receives set $F$, recall that it knows all sending message by source, it observes for $f_j \in F, j = 1, \ldots, k'_2$,
\[
\omega_j = f_j - v_j - \sum_{i=1}^{k_1} \theta_{i,j}x_i \tag{23}
\]
\[
= (\hat{x}_j - v_j) + \sum_{i=1}^{k_1} \theta_{i,j}(\hat{x}_i - x_i)
\]
\[
= \Delta v_j + \sum_{i=1}^{k_1} \theta_{i,j}\Delta x_i
\]

since $\Delta v_j, \Delta x_j, \Delta r_j$ are injected error symbols, and adversary only can affect $z$ links at most. Also we have $k_3 + k'_2 = z$, therefor there must be at least one $\omega_i \neq 0$, otherwise it implies all injected $\Delta v_j, \Delta x_j, \Delta r_j$ equal to zero, which contradicts assumption.

So once upstream links are attacked first time, either node $A$ or node $B$ can detect it, and if there are more than one upstream links attacked, by Lemma 1, it won’t need detection of intermediate nodes in subsequent transmissions. Then we consider the attacking scenario as

Case-2-1: $e = 1$ in first attack.

Consider a received vector as $[21]$ with a single corrupted symbol, the possible position is

1.1) $\hat{x}_j, j \in [1, k_1]$ is attacked or

2.1) $\hat{v}_j, j \in [1, k'_2]$ is attacked or

2.3) $\hat{r}_j, j \in [1, k_3]$ is attacked.

For single error on either (2.1) or (2.2), it’s not hard to check that node $A$ observes all $\delta_j \neq 0 \in \Delta$. Node $A$ can observe received vector,
\[
(\hat{x}_1, \ldots, \hat{x}_{k_1}, \hat{v}_1, \ldots, \hat{v}_{k'_2}, \hat{r}_1, \ldots, \hat{r}_{k_3})
\]
since $k_3 \geq 2$ and $\hat{r}_j$ is redundancy of $\hat{x}_j, \hat{v}_j$, it’s not hard to see that node $A$ can identify single error symbol by MDS property.

For single error on (2.3), node $A$ observes single $\delta_j \neq 0$ of $\Delta$ and the other $\delta_j = 0$, under which node $A$ believes that $\hat{r}_j$ was corrupted.

Once node $A$ identifies error link, it sends CS signal to node $B$ to trigger node $B$ sending $W$ to sink.

Case-2-2: $e \geq 2$ in subsequent attack.

For the case that (2.1) or (2.2) happened in first time, assume $\hat{x}_j$ or $\hat{v}_j$ was attacked in previous transmission. Given a received vector $[21]$, node $A$ observes
\[
\delta_j - \eta_{i,j}^{-1}\eta_{i,k_3}^{-1}\delta_k
\]
\[
= \sum_{i=1}^{k_1+k'_2} \eta_{i,j}\Delta x_i + \Delta r_j - \sum_{i=1}^{k_1+k'_2} \eta_{i,k_3}\Delta x_i + \Delta r_k
\]
\[
= \sum_{i=1}^{k_1+k'_2} (\eta_{i,j} - \eta_{i,k_3})\Delta x_i + \Delta r_j - \eta_{i,j}\eta_{i,k_3}\Delta r_k
\]

where $\delta_j, \delta_k \in \Delta, j = 1, \ldots, k_3 - 1$. Since $[24]$ has removed possible non-zero $\Delta x_i$ detected in first attack, if there is any non-zero $[24], j = 1, \ldots, k_3 - 1$, there must be new error link happened, node $A$ sends CS signal to node $B$, otherwise node $A$ observes all zero of $[24]$, recall that node $A$ has already identified $\hat{x}_i$ or $\hat{v}_j$ in previous, it sends set $F$ to node $B$, each of $f_j$ defined as
\[
f_j = \begin{cases} 
\hat{v}_j + \sum_{i=1}^{k_1} \theta_{i,j}\hat{x}_i & \text{if } \hat{x}_i \text{ happened} \\
\hat{v}_j + \sum_{i=1}^{k_1} \theta_{i,j}\hat{x}_i & \text{if } \hat{x}_j \text{ happened}
\end{cases}
\]

And similarly as $[23]$ node $B$ observes
\[
\omega_j = \begin{cases} 
\Delta v_j + \sum_{i=1}^{k_1+k'_2} \theta_{i,j}\Delta x_i + \Delta r_j & \text{if } \hat{x}_j \text{ happened} \\
\Delta v_j + \sum_{i=1}^{k_1+k'_2} \Delta x_i & \text{if } \hat{x}_l \text{ happened}
\end{cases}
\]

for $f_j \in F, j = 1, \ldots, k'_2$.

Notice that both of $[24]$ and $\omega_j$ has canceled item $\Delta x_i$ or $\Delta v_i$, together with observation on node $A$, there are $z - 1$ equations for $z - 1$ at most new injected error symbols. Since $k'_2 + k_3 = z - 1$ and adversary can inject $z - 1$ at most error symbols besides $\hat{x}_i$ or $\hat{v}_j$, if new error position happened, there must be nonzero $\omega_j$, otherwise it gives contradiction to linear property.

For the case $[23]$ happened first time, assume $\hat{r}_i$ was attacked in first time. Given a received vector $[21]$, node $A$ observes corresponding $\Delta$ first.

Recall definition of $\Delta$, if there is $\delta_j \neq 0, j \neq l$, it indicates nonzero $\Delta x_i, \Delta r_j, j \neq l$ and must be new error position happened, node $A$ sends CS signal to node $B$. If node $A$ has observation $\delta_j = 0, j = 1, \ldots, k_3, j \neq l$, which is
\[
\sum_{i=1}^{k_1+k'_2} \eta_{i,j}\Delta x_i + \Delta r_j = 0, j \neq l
\]
it sends set $F[22]$ to node $B$ and node $B$ follows process $[23]$ to observe
\[
\omega_j = \Delta v_j + \sum_{i=1}^{k_1+k'_2} \delta_j \Delta x_i, j = 1, \ldots, k'_2
\]

If there is new error position happened, there must be nonzero $\omega_j$ which triggers node $B$ sending claim $W$ to sink, otherwise all $\omega_j = 0$ indicate no new error position happened.

Case-3: $|\Delta| = 0, k'_2 = z$

By the condition, since $k_1 + k'_2 = n$ the row has structure
\[
(x_1, \ldots, x_k, v_1, \ldots, v_{k'_2}, \hat{x}_1, \ldots, \hat{x}_{k_3}, x_{k+1}, \ldots, x_n)
\]
where $x_i \in \mathcal{X}$. Let $G$ be generator matrix for $(n + z, n)$ systematic MDS code, and
\[
G = (I_{n \times n} E)
\]

where $I_{n \times n}$ is unit matrix and $E$ is a $n \times z$ matrix, entry of which is denoted by $\eta_{i,j}, 1 \leq i \leq n, 1 \leq j \leq z$, which are chosen uniformly at random from nonzero entries of a large finite field.
For a received \((\hat{x}_1, \ldots, \hat{x}_{k_1}, \hat{x}_{k_1+l}, \ldots, \hat{x}_{k_1+k'_2})E\), node \(A\) operates as
\[
(\hat{x}_1, \ldots, \hat{x}_{k_1}, \hat{x}_{k_1+l}, \ldots, \hat{x}_{k_1+k'_2} E)
\]
and send the following set to node \(B\),
\[
F = \{ f_j = \sum_{i=1}^{n} \eta_{i,j} \hat{x}_i | j = 1, \ldots, z \}
\]
(26)

Node \(B\) receives set \(F\), since node \(B\) has knowledge about true message symbols, it can operate as
\[
\Omega = \{ \omega_j = f_j - \sum_{i=1}^{n} \eta_{i,j} x_{i,j} | f_j \in F, j = 1, \ldots, z \}
\]
not hard to see that \(\omega_j = \sum_{i=1}^{n} \eta_{i,j} \Delta x_i\).

Case-3-1: \(e = 1\) in first attack.

Node \(B\) observes all \(\omega_{i,j} \neq 0\) in first time, it knows error happened, node \(B\) observes
\[
\omega_1 = \sum_{i=1}^{n} \eta_{i,1} \Delta x_i
\]
\[
\omega_2 = \sum_{i=1}^{n} \eta_{i,2} \Delta x_i, j = 2, \ldots, z
\]
Assume \(\hat{x}_1\) was attacked, node \(B\) will has observation as \(\eta_{i,j}, j = 2, \ldots, z\), thus node \(B\) trust that \(\hat{x}_1\) was attacked and sends claim \(W\) to sink.

Case-3-2: \(e \geq 2\) in subsequent attack.

For this case by applying the proof of Claim [1] it will show adversary cannot hide new error link by attacking multiple links. Thus once there is new error link happened, it triggers node \(B\) sending \(W\) to sink.

Case-4: \(|\Delta| = 1, k'_2 = z - 1\).

By the condition, the row has structure as
\[
(x_1, \ldots, x_{k_1}, v_1, \ldots, v_{k'_2}, r_1)
\]
(27)

Given a received vector \((27)\), we have
\[
\Delta = \delta_1 = \sum_{i=1}^{k_1+k'_2} \eta_{i,1} \Delta x_i + \Delta r_1
\]
The first time node \(A\) observes \(\delta_1 \neq 0\), it implies that there must be nonzero \(\Delta x_i, \Delta r_1\), and node \(A\) can send \(CS\) signal to node \(B\). However single redundant symbol \(r_1\) cannot help node \(A\) identifying erroneous position, it says no matter either \(\delta_1 = 0\) or \(\delta_1 \neq 0\) observed in subsequent transmission, node \(A\) cannot find out if new error position happened. We need to consider another scheme.

If certain row has property of \(k'_2 = z - 1\), it indicates that \(\left[ \frac{b}{a-c} \right] \geq z - 1\). And since \(b < z(a-c)\) by tight condition, we focus on \(z - 2 < \frac{b}{a-c} < z\).

The intuition of this case is that we first show for most of \(b \in ((z - 2)(a-c), z(a-c))\), we could arrange \(k'_{2}\) for each row of \(X\) properly such that situation of \(X\) falls into cases we have solved. Then we discuss the detection and decoding scheme on more specific condition of \(b\).

First we consider network under two conditions: either \(b < z(a-c) - 1\) or \(b\) is even subjected by \(b < z(a-c) - 1\), \(z = 2\). It’s not hard to check that we could modify encoding scheme slightly such that following properties holds for each row of \(X\):

- either \(k'_2 = z\) for some row of \(X\), i.e., \(|\Delta| = 0\)
- or \(0 \leq k'_2 \leq z - 2\) for some row of \(X\), i.e., \(2 \leq |\Delta| \leq z\).

Proof: We first consider the network with \(b < z(a-c) - 1\), \(z > 2\). For \(b = z(a-c) - \omega, 2 \leq \omega \leq z\), we could assign \(k'_2 = z\) such that each row of first \((a-c-1)\) rows of \(X\) carries \(z\) symbols giving \(|\Delta| = 0\) and the last row of \(X\) carry \((z-\omega)\) symbols. Notice that we have \(0 \leq z-\omega \leq z-2\) giving \(2 \leq |\Delta| \leq z\).

For \(b = z(a-c) - \omega, 1 \leq t < a-c, 1 \leq \omega \leq z - 1\), we could arrange \(k'_2\) such that:

- Each row of first \((a-c-t-1)\) rows of \(X\) carries \(z\) symbols,
- The \((a-c-t)\)th row of \(X\) carries \((z-\omega)\) symbols,
- The \((a-c-t+1)\)th row carries \(1\) symbol,
- On the remaining row of \(X\), no \(v_i\) is carried.

which gives that \(|\Delta| = 0\) for first \((a-c-t-1)\) rows of \(X\), \(2 \leq |\Delta| \leq z\) on \((a-c-t)\)th row of \(X\), \(|\Delta| = z - 1 \geq 2\) on \((a-c-t+1)\)th row of \(X\) and \(|\Delta| = z > 2\) on the remaining row of \(X\).

And for the network with \(b\) is even under \(b < z(a-c) - 1, z = 2\), the result is trivial.

Detection ability of rows having \(|\Delta| = 0\) and \(2 \leq |\Delta| \leq z\) have been discussed corresponding to Case-1 and Case-2 respectively and the detection ability of rows having \(|\Delta| = z\) will be discussed in Case-4. Therefore we could assume intermediate nodes have a detectable structure of \(X\) under condition either \(b < z(a-c) - 1, z > 2\) or \(b\) is even subjected by \(b < z(a-c) - 1, z = 2\).

Next we consider network under conditions: either \(b = z(a-c) - 1, z > 2\) or \(b\) is odd subjected by \(b < z(a-c) - 1, z = 2\), it’s not hard to check that

4.1 - For \(b = z(a-c) - 1, z > 2\), we can arrange each row of \(k'_2\) such that \(|\Delta| = z\) for each row of first \((a-c-1)\) rows of \(X\) and \(|\Delta| = 1\) for the last row of \(X\);

4.2 - \(b < z(a-c) - 1, z = 2\) and \(b\) is odd. we could let \(X\) has structure as

4.2.1 either \(|\Delta| = 2\) or \(|\Delta| = 0\) on the first \((a-c-1)\)th row of \(X\) and

4.2.2 \(|\Delta| = 1\) on the last row of \(X\).

Theorem 2. Given \(b = z(a-c) - 1, z > 2\) or \(b\) is odd subjected by \(b < z(a-c) - 1, z = 2\), there is a solution for sink to decode correctly without claim from node \(B\) after sink identified single error on upstream link.

Proof: Given adversary only corrupts single link on upstream in first attack and attacks new error links in subsequent transmission. Assume that \(i\)th upstream link was identified in previous transmission, denote the remaining network by \(G'\setminus i\).

Feedback Condition-1: \(b = z(a-c) - 1, z > 2\).

Recall (4.1), we first consider rows of received \(X\) having \(|\Delta| = z\) on upstream, which is discussed in Case-1, it says that in subsequent transmission if new error link happened, intermediate nodes will find it out. If no claim is sent by node
Then we see, topology of network: is independent with until carrying symbols with is z

\[ \text{Note that without a little rigorous, we will use } R_1 \text{ to represent these independent symbols on } (a-c-1) \text{ rows of } X \text{ in following.} \]

Then we consider the \((a-c)\)th row of received \(X\) with \(|\Delta| = 1\). Node A sends received \(v_i, i = 1, \ldots, z-1\) to node B in next transmission. Since node B knows all true \(v_i\) symbols, if there is any symbol corrupted, it must be detected and claim will be sent which will let sink has an MDS code, otherwise it does nothing.

With nothing of information from node B, it indicates that all these received symbols \(v_i, i = 1, \ldots, z-1\) are reliable.

Recall that in absence of claim from node B, sink can trust first \((a-c-1)\) rows of upstream on the remaining network \(G\setminus i\). Denote the remaining network \(G\setminus i\) excluding first \((a-c-1)\) rows of upstream by \(G'\).

We show that there exists a collection of link subset on \(G'\), which has at least \(UB - R_1 - (z-1)\) symbols independent with \(R_1, v_i\).

Let link subset on \(G'\) be formulated as: remove links carrying symbols \(v_i, i = 1, \ldots, z-1\) first, the number of which is \(z-1\) and remove another \((z-1)\) links as following priority order: first removing upstream links, and then downstream link until \((z-1)\) links have been removed altogether.

Not hard to see symbols in the link subset we defined is independent with \(R_1, v_i\). Then we observe the number of symbols in this link subset. We organize discussion by topology of network:

Category-1: \(n > 2(z-1)\)

By above description, the number of independent symbol on the link subset of \(G'\) is

\[ R_2 = (n - 1 - 2(z-1))(c+1) + mc \]

(28)

Then we see,

\[ R_1 + R_2 + (z-1) \]

\[ = (n - z)a + (m - z)c + (z-1)a - (z-2)c - z \]

\[ = UB - b + (z-1)a - (z-2)c - z \]

\[ \geq UB + 2c - a - z + 2 \] (29)

where (29) follows that \(b \leq z(a-c) - 1\) and \((z-1)\) is from the number of \(v_i, i = 1, \ldots, z-1\).

Since \(b < \min\{z(a-c), zc - (z-2)a\}\) by tight condition [1], we focus on the condition \(z(a-c) \leq zc - (z-2)a\), otherwise we cannot have \(b = z(a-c) - 1\). Then we have

\[ \frac{c}{a} \geq \frac{z-1}{z} \]

\[ \frac{a}{a-c} \geq z \] (30)

Note that we don’t have to consider tight condition [3] since \((m - z)(a-c) < z(a-c)\) for \(m < 2z\), no matter how there is always \(b < z(a-c) - 1\).

Then we observe,

\[ 2c - a - z + 2 \geq 2c - a - \frac{a}{a-c} + 2 \] (31)

where (31) follows (30), let \(a - c = x\), we have

\[ 2c - a + 2 - \frac{a}{x} = \frac{-2x^2 + (a+2)x - a}{x} \geq 0 \]

not hard to see that the root of \(-2x^2 + (a+2)x - a\) are \(x_1 = 1, x_2 = \frac{a}{2}\), which says that as long as \(1 \leq x \leq \frac{a}{2}\), the result of \(-2x^2 + (a+2)x - a\) are no less than zero.

Since \(x = a - c\), recall (30) and \(z \geq 2\), not hard to check that we have \(1 \leq x \leq \frac{a}{2}\), which shows that

\[ \frac{2c - a + 2 - \frac{a}{x}}{x} = \frac{-2x^2 + (a+2)x - a}{x} \geq 0 \]

Then we have

\[ R_1 + R_2 + (z-1) \geq UB \] (32)

Category-2: \(z < n \leq 2(z-1)\)

Similarly, on the link subset of \(G'\), the independent symbol is

\[ R_2 = (m - (2(z-1) - (n-1)))c \]

\[ = (n + m - 2z + 1)c \]

then the total reliable symbols we have

\[ R_1 + R_2 + (z-1) \]

\[ = (n + m - 2z + 1)c + (n-1)(a-c) + (z-1) \]

\[ = UB - b + (z-1)a - (z-2)c - (n-z) \]

\[ \geq UB + 2c - a - (n-z) + 1 \]

\[ = UB + 2c - a - n + z + 1 \]

(33)

(34)

where (33) follows that \(b \leq z(a-c) - 1\).

And since tight condition [2], i.e., \(b < \min\{z(a-c), (n-z+2)c - (n-z)a\}\), we consider the case \(z(a-c) \leq (n-z+2)c - (n-z)a\), which gives

\[ \frac{c}{a-c} \geq \frac{n}{2} \]

\[ \frac{2a}{a-c} - 2 \geq n \] (35)

also we have \(z(a-c) \leq zc - (n-z)a\) since \(n \leq 2(z-1)\), which gives \(z \geq \frac{na}{2c}\). Similarly, we ignore tight condition [4].
Then we observe,

\[
2c - a - n + z + 1 \\
\geq 2c - a - n + \frac{na}{2c} + 1 \\
= 2c - a - (1 - \frac{a}{2c})n + 1 \\
\geq 2c - a - \frac{2c - a - 2a}{2c} \left( \frac{2a}{a - c} - 2 \right) + 1 \\
= 2c - a - \frac{2c - a}{2c} \frac{2c}{a - c} + 1 \\
= 2c - a - \frac{a}{a - c} + 2 \frac{a}{a - c} + 1 \\
= 2c - a - \frac{a}{a - c} + 3
\]

In category-1, we have shown that \( 2c - a - \frac{a}{a - c} + 2 \geq 0 \), thus in category-2, we have

\[
R_1 + R_2 + (z - 1) > UB
\]  \hspace{1cm} (36)

Notice that above proof all shows that network we need to consider is subjected by \( m \geq 2z \).

**Feedback Condition-2**: \( b \) is odd subjected by \( b < z(a - c) - 1, z = 2 \).

Recall (4.2), similarly we first consider rows having either \( |\Delta| = z \) or \( |\Delta| = 0 \) of received \( X \). By Case-1 and Case-3, we know intermediate nodes can detect new error position after first attack. Also there \( (a - c - 1) \) rows satisfying these condition.

Then we observe the independent symbols for the case that no new error link happened after first attack. Since there are \( \lfloor \frac{b}{2} \rfloor \) rows having \( |\Delta| = z \) and there are \( b - 1 \) \( v_i \) symbols on first \( (a - c - 1) \)th rows, so we should have

\[
R_1 = (n - 2)(a - c - 1) + (b - 1) - \lfloor \frac{b}{2} \rfloor
\]

where \( \lfloor \frac{b}{2} \rfloor \) is number of symbols lost on identified single link.

Following the same logic in Feedback Condition-1,

Category-1: \( n > 2(z - 1), \) we have

\[
R_2 = (n - 1 - 2(z - 1))(c + 1) + mc = (n - 3)(c + 1) + mc
\]

Then we see

\[
R_1 + R_2 + 1 = UB + c - \lfloor \frac{b}{2} \rfloor - 1 \\
> UB + c - \left( \frac{2(a - c) - 1}{2} \right) - 1 \\
> UB + c - 1 - (a - c - 1) \\
= UB + 2c - a
\]

recall (30), we have \( \frac{c}{a} \geq \frac{1}{2} \), which indicates that

\[
R_1 + R_2 + 1 \geq UB
\]  \hspace{1cm} (37)

Category-2: \( z < n \leq 2(z - 1) \). Obviously, there is no such network.

Next we show by the result (32), (30), (37), we can design a decoder for sink. Specifically, let set \( S \) be all forward link on \( G' \). Define two subsets of \( S \) as,

\[
S_1 = \{ \text{links which carry symbols} \ v_i \ \text{on} \ G' \} \\
S_2 = S \setminus \{i, S_1 \}
\]

where \( i \) is the index of link identified in previous transmission.

The intuition of decoder is to directly consider different sets of \( z - 1 \) links as removing set and check the remaining links for consistency. When it finds a consistent set, the decoding process ends. Thus we consider all possible sets of \( 2(z - 1) \) links and show that the remaining links carry a full rank complete decoding set.

The remaining symbols must contain a full rank non-erroneous set from which all the message symbols can be correctly decoded, along with others that may or may not be erroneous. Therefore if the considered subset (removing set) includes all the actual erroneous links, the remaining symbols will be consistent and give the correct decoding, whereas if the remaining symbols contain errors there will be inconsistency with the full rank non-erroneous set.

The decoder exhaustively goes through all sets of \( (z - 1) \) forward links in turn, checking if the remaining forward links are consistent. If they are consistent, they give the correct message. Let new error link set be \( E = E_1 \cup E_2 \) in \( G' \), where \( E_1 \subseteq S_1, E_2 \subseteq S_2 \) and \( |E_1| + |E_2| \leq z - 1 \).

For the case that \( E = E_1 \subseteq S_1 \), i.e., all new \( (z - 1) \) at most error happened in \( S_1 \), note that since \( \hat{v}_i \) can be detected on node \( B \), we consider the new errors that occurred on \( Y \) of \( S \) for this case. If we consider the remaining link subset by (32), (30), (37), it indicates that under \( E = E_1 \) it will give more than one full rank non-erroneous link subset since \( |S_2| > z - 1 \).

Starting from this case, we show decoder can finish decoding process as following order:

**O-1** Assume \( E = E_1 \subseteq S_1 \), i.e., all new errors happened in \( S_1 \), observing whether there is consistent result by removing \( \{S_1, \hat{S}\} \), where \( \hat{S} \subseteq S_2 \) is followed by priority order. If it successes, output the result, otherwise goes to next,

**O-2** Assume both of \( E_1 \) and \( E_2 \) are non-empty, then make consistent check in remaining link subset. If it successes, output the result, otherwise goes to next,

**O-3** Above two processes failed, it indicates that \( E = E_2 \subseteq S_2 \), decoder decode in remaining links.

O-1: New errors set \( E \) only happened in \( S_1 \), i.e., \( E = E_1 \subseteq S_1 \).

Decoder first removes links in \( S_r = \{S_1, \hat{S}\} \), where \( \hat{S} \subseteq S_2 \) and \( |\hat{S}| = z - 1 \). Since \( |S_2| > z - 1 \), we can have more than one subset \( \hat{S} \). Recall (32), (30), (37), the remaining link subset together with \( R_1, \hat{v}_i \) will provide no less than \( UB \) non-erroneous symbols. And clearly this kind of link subset is more than one.

Clearly for \( E \subseteq S_1 \), correct decoding occurs since all possible remaining link subsets together with \( R_1, \hat{v}_i \) will give consistent result. However, if \( E \not\subseteq S_1 \), it indicates that by changing \( \hat{S} \), there must be an inconsistent result, then decoder goes to next.
O-2: New errors happened in both of $S_1$ and $S_2$, i.e., $|E_1| \neq 0, |E_2| \neq 0, 0 < |E_1| + |E_2| \leq z - 1$. We assume $|E_1| \neq 0$, it implies that $z > 2$, otherwise $|E_2| = 0$ for $z = 2$ since one error link has been identified.

O-1 decoded unsuccessfully, it implies that $S_1$ doesn’t include all new error links, i.e., $|E_2| \neq 0$.

Consider removing set $S_r = \{S_1, \hat{S}\}$, $S_1$ includes $E_1$ erroneous subset, if $E_2 \subset \hat{S}$, similarly, by [32], [36], [37], the sum of $R_1, S \setminus S_r$ and $\hat{v}_i$ is no less than $UB$, and we show one consistent result at least will be given.

Let $\hat{S} = \{E_2, S_3\}$, where $S_3 \subset S_2 \setminus E_2$, $|S_3| + |E_2| = z - 1$. Since $|E_2| < z - 1$, it implies that $|S_3| \geq 1$. Note that if we hold $E_2$ unchanged and change set $S_3$, we could have a group of $S$ which have different subset $S_3$.

Recall that $E$ is new error link set, let $\triangle E$ is injected error vector set corresponding to $E$, the element of which is injected error vector denoted by $\triangle e$ on $e_i \in E$.

For an set $S_r$, suppose $S \setminus S_r$ includes error link, it’s not hard to see that the result from $(S \setminus S_r, R_1, v_i)$ will pollute the original clean message symbol, we claim:

Claim 2. The polluted message symbol resulted from $(S \setminus S_r, R_1, v_i)$ equals to the clean symbol injected by a linear combination of erroneous in $\triangle E$.

Proof: Consider we compute message symbols from $(S \setminus S_r, R_1, v_i)$. Suppose $S \setminus S_r$ includes erroneous, let $\hat{c} = c + \triangle e$ be polluted symbols in $S \setminus S_r$, where $c$ is clean symbol and $\triangle e$ is injected error.

According to encoding scheme, each symbol in $(S \setminus S_r, R_1, v_i)$ can be written,

$$\hat{c} = H(x, y) = c + \triangle e$$

where $x, y$ represent for message symbols $x \in X, y \in Y$, respectively and $H(\cdot)$ is a linear function determined by encoding scheme.

Since $|x| + |y| = UB$ and $|(S \setminus S_r, R_1, v_i)| \geq UB$, we have enough independent linear function $H(x, y)$ to compute $x, y$.

And by the property of linear, it’s not hard to see that the result of $\hat{x}, \hat{y}$ equals to

$$\hat{x} = x + H_1(E)$$
$$\hat{y} = y + H_2(E)$$

where $H_i(E)$ is a linear function for injected error set determined by encoding scheme.

Then we see the following claim.

Claim 3. There exists inconsistent output for two removing sets $S_1 = \{E_2, S_3\}$, $S_2 = \{E_2, S_3\}$ where $E_2'$ is subset of $E_2$, $|E_2'| < |E_2|$, and $S_3$ is error free subset of $S_2$, $|E_2'| + |S_3| = z - 1, i = 1, 2$.

Proof: We consider the case that $|E_1| = 1, |E_2| = z - 2$ and $|E_2'| = 0$, which says the removing subset $S_i, i = 1, 2$ doesn’t includes any error link, i.e., $E_2 \not\subset S_i$, giving $S_1 = S_2 = S_2'$. This is obviously the worst case since $S_2 \setminus S_i$ includes all $z - 2$ error links.

Let $S_3 = \{S_1', i\}, S_3' = \{S', j\}$, where $i, j, i \neq j$ are index of forward link and $i, j \notin S', |S'| = z - 2$. Then we use $S_2'(i), S_2'(j)$ to represent for $S_1', S_2'$ respectively.

Assume $S \setminus \{S_1, S_2'(i), S_2'(j)\}$ give consistent result together with $R_1, v_i$ respectively. Note that according to result from $(S \setminus S_r, R_1, v_i)$, where $S_r = \{S_1, S_2'(i), \{S_1, S_2'(j)\}, \}$ sink can compute the symbols which are in the removing set $S_2'(i), S_2'(j)$. Then since the consistency occurred, we should have following properties between $S_2'(i)$ and $S_2'(j)$:

Symbols on $j$th link computed from the result of $(S \setminus \{S_1, S_2'(i)\}, R_1, v_i)$ are consistent with symbols on $j$th in $S_2'(j)$.

Define $c_{j,i}$ is a symbol on $j$th link computed from the result of $(S \setminus \{S_1, S_2'(i)\}, R_1, v_i)$ and $c_{j,j}$ is a symbol on $j$th link computed from the result of $(S \setminus \{S_1, S_2'(j)\}, R_1, v_i)$. Similar, we use $c_{i,i}$ as a symbol on $i$th link in $S_2'(i)$ and $c_{i,j}$ as a symbol on $j$th link in $S_2'(j)$. Since $S_2'(i)$ and $S_2'(j)$ are error free link set by definition, $c_{i,i}$ and $c_{i,j}$ are true symbols, by above, we have,

$$c_{j,i} = c_{j,j} + H_i(e)$$
$$c_{j,j} = c_{j,i}$$

where $H_i(\cdot)$ is linear function of injected error determined by coding scheme, which $e$ is linear combination of error vector injected in $z - 2$ links by Claim 2 and belongs to $S \setminus \{S_1, S_2'\}, i = 1, 2$. Since consistency occurred, we have $c_{i,i} = c_{j,j}$, which implies that $H_i(e) = 0$.

Suppose that $i$ and $j$ in $S_2'(i), S_2'(j)$ respectively are the index of downstream links, it implies that there are $c$ equations having $H_i(e) = 0, j = 1, ..., c$.

Then decoder changes $j$ in $S_2'(j)$ to $k$, where $k \neq j \neq i, k \notin S'$ and let $k$ be index of downstream. Repeat above observation, since consistency happened, it gives another group of linear functions $H_k(e) = 0, k = 1, ..., c$. And note that $m \geq 2z$ for $z > 2$, thus we have at least $(m - 1)c$ linear function $H_i(e) = 0$.

Recall that we have $(z - 2)a$ injected error at most in $E_2$, by [30], [35], it’s not hard to see that $2c \geq a$, which gives $(m - 1)c \geq (z - 2)a$, and totally we have $H_i(e) = 0, i = 1, ..., (m - 1)c$, which indicates that $e$ equals to zero, it obviously contradicts to our assumption that we should have non-zero injected error vector $e$.

Claim 3 indicates a decoding strategy: there is only one removing set $S_r = \{S_1, \hat{S}\}$, where $\hat{S} = \{E_2, S_3\}$, $|E_2| < z - 1, |S_3| > 0, |E_2| + |S_3| = z - 1, S_3 \subset S_2$ such that when holding $E_2$ unchanged, sink changes $S_3$, the $(S \setminus S_r, R_1, v_i)$ give the consistent output.

If sink cannot find $E_2$ satisfying above requirement, it says assumption 3 happened and goes to next case.

Case-3: New error only happened in $S_2$ and $E = E_2 \subset S_2$, i.e., $|E_1| = 0, |E_2| = z - 1$.

In this case the symbols in $S_1$ are clean. Still we consider removing set $S_r = \{S_1, \hat{S}\}$ first. Sink can have a result from $(R_1, S \setminus S_r, v_i)$. 
Since $S_1$ is clean under this case, sink could trust symbols in it. Then sink computes $v_i$ by the result from $(S \setminus R_t, R_i, v_i)$. If the result is inconsistent with corresponding symbols in $S_1$, sink choose different $S_t$ to repeat above procedure till consistency occurs. We show that sink can trust this result. By occurred consistency, it gives,

$$v_i = H_i(\hat{v}_i) = H_i(v_i) + H_i(\Delta v_i)$$

where $v_i \in S_1$ and $\hat{v}_i$ are symbols computed from the result of $(S \setminus S_r, R_1, v_1)$, $\Delta v_i$ are linear combination of injected error vector by Claim 2 and $H_i(\cdot)$ is a linear function determined by encoding scheme.

Since consistency, $H_i(\Delta v_i) = 0$. Similarly, we will have,

$$y_j = H_j(\hat{y}) = H_j(y) + H_j(\Delta y)$$

where $y_j \in S_1$ and $\hat{y}$ are symbols computed from the result of $(S \setminus S_r, R_1, v_1)$, $\hat{y} = y + \Delta y$, $y$ represent true symbols, $\Delta y$ are linear combination of injected error vector by Claim 2 and $H_j(\cdot)$ is a linear function determined by encoding scheme.

Then we have $H_j(\Delta y) = 0$.

Note that each $\Delta v_i, \Delta y$ is linear combination of injected error vector and we have $(z - 1)$ links at most corrupted, since $|S_1| = z - 1$, with all $H_j(\Delta y) = 0$, $H_i(\Delta v_i) = 0$, it indicates that these all injected error equals to zero. Thus sink can trust the result from $(S \setminus S_r, R_1, v_1)$.

C. Summary of Error Signaling Procedure

For received $\hat{X}$, we define $\Delta l, l = 1, \ldots, a - c$ for each row of $\hat{X}$ as definition 16. We summarize the error signaling procedure on intermediate node $A$ and $B$ for as follows:

1) For $|\Delta l| = z$, node $A$ observes nonzero $\delta_j \in \Delta_l$ first time, it sends $CS$ single to node $B$ and node $B$ sends $W$ to sink. And Claim 1 shows adversary cannot hide new error position for node $A$ in subsequent attack.

2) For $2 \leq |\Delta l| < z$, if node $A$ observes nonzero $\delta_j \in \Delta_l$ first time it sends $CS$ to node $B$; for observation all $\delta_j = 0$, it sends set $22$ to node $B$, either of which will help intermediate nodes identifying happened error. In subsequent transmission, node $A$ and $B$ cooperate following Case 2-2.

3) For $|\Delta l| = 0$, each time node $A$ sends set $26$ to node $B$, according which node $B$ can identifying new error position once it happened.

4) For $|\Delta l| = 1$, intermediates nodes cooperates directly as Case 4 described.

Notice that for all rows of $X$, if no new error position is detected, amount of transmission on feedback equals to $b$.

D. Summary

By above analysis, when node $A$ sends $CS$ signal or node $B$ sends claim to sink, it causes overhead problem on feedback and downstream, however this overhead only happens when there is new error link occurred, and by Lemma 1 after identifying two error links, sink doesn’t need any side information from feedback or claim. Once either node $A$ sends two times $CS$ signal or node $B$ sends claim two times, it doesn’t need any side information in future transmission, which means that comparing to the whole transmission, these overhead can be ignored.

VII. Decoding

At steps in which error signaling occurs, all information is forwarded to the sink, enabling it to identify the erroneous links and decode correctly as described in the previous subsection. In this section we show that the sink is also able to decode correctly at steps in which no error signaling occurs. Let $e$ be the number of previously identified erroneous links.

The sink considers the network excluding these $e$ links, which can contain at most $z - e$ erroneous links.

The sink considers each subset of $z - e$ links in turn, assuming it to be the erroneous set and checking whether this assumption is consistent with its observations, i.e. whether the symbols that are assumed to be non-erroneous have consistent values. We will show that if the remaining symbols are consistent, then they give the correct decoding. The argument shows that the equations corresponding to the remaining symbols must contain a full rank non-erroneous set from which all the message symbols can be correctly decoded, along with others that may or may not be erroneous. Therefore if the considered subset includes all the actual erroneous links, the remaining symbols will be consistent and give the correct decoding, whereas if the remaining symbols contain errors there will be inconsistency with the full rank non-erroneous set. The arguments relies on the property that except for redundant symbols on the upstream links, the remaining code symbols received by the sink form an MDS code.

For the case $z = 1$, if an error has previously been signaled, the single erroneous link has been identified. If no errors have been signaled, this means that there are no errors in $X$. Therefore, message symbols $X, F$ are decoded correctly from $X$, and the MDS property of the generic linear code ensures correct decoding of message symbols $Y$ under errors in $Y$ on any single link.

We discuss the case $z \geq 2$ as following structure:

Case 1: $e \geq 2$.

In this case, by Lemma 1 the feedback link is no longer needed. We show that removing any $2(z - e)$ links in addition to the $e$ identified erroneous links still leaves a full rank non-erroneous set along with at least one additional symbol. To find the worst-case number of remaining non-erroneous MDS symbols at the sink, we remove $2z - e$ links from the original network in the following priority order: first removing upstream links, and then downstream links, until $2z - e$ links have been removed altogether, with $e$ set to its minimum value, 2. Note that $2z - 2z \geq z$ since $z \geq 2$.

Case 1-1: $2z - 2 \leq n$. The worst-case number of remaining non-erroneous MDS symbols is $R_1 = (a - c)(n + 2 - 2z) + c(n + m + 2 - 2z) = a(n + 2 - 2z) + cm$. For category 1 and
Thus, the condition for correct decoding is satisfied. For category 2 and 4 networks, applying the inequality \( b \leq (n - z + 2)c - (n - z)a \) from (2) and (4), we have
\[
K_1 - UB = (n + 2 - 2z)a + mc - (n - z)a + (m - z)c + b \\
= 2a - z(a - c) - b \\
\geq 0.
\]
where the last inequality follows from the assumption \( 2z - 2 \leq n \). This also satisfies the condition for correct decoding.

Thus, the condition for correct decoding is satisfied.

Case 2: \( e < 2 \) links not including the feedback link have previously been identified as erroneous. By the arguments in the previous subsection, if no error is being signaled, there are two possibilities: either there are no errors in \( X \) on the remaining links, or the feedback link is erroneous.

Case 2-1: The feedback link is erroneous. For any size-(\(z - e\)) subset considered by the sink, at most \( z - e - 1 \) other forward links in the remaining network are erroneous.

If the size-(\(z - e\)) subset considered by the sink contains the feedback link, the worst-case number of remaining non-erroneous MDS symbols is obtained by removing \(2z - e - 2\) forward links from the original network in the same priority order as in Case 1, with \( e = 0 \). This is equal to \( SB2 \), which is greater than or equal to \( UB \) by the conditions (1) and (4), so correct decoding occurs.

If the size-(\(z - e\)) subset considered by the sink does not contain the feedback link, the corresponding assumption is that all the symbols in \( X \) other than those on the \( e \) identified erroneous links are correct. The worst-case number of remaining non-erroneous MDS symbols is obtained by removing \( z - 1 \) other links, with \( e = 0 \). This gives \( a(n - z) + c(m - z + 1) + k \) remaining non-erroneous MDS symbols, which is greater than \( UB \), so correct decoding occurs.

If the size-(\(z - e\)) subset considered by the sink contains the feedback link, the worst-case number of remaining non-erroneous MDS symbols is obtained by removing \( z - 1 \) forward links from the original network in the same priority order as in Case 1, along with the symbols in \( Y \) from \( z - e \) other links, with \( e = 0 \). This gives \( a(n - z) + c(m - z) + a \) remaining non-erroneous MDS symbols, which is greater than \( UB \), so correct decoding occurs.
