Abstract
Let $\Omega \subset \mathbb{R}^3$ be an open and bounded set with Lipschitz boundary and outward unit normal $\nu$. For $1 < p < \infty$ we establish an improved version of the generalized $L^p$-Korn inequality for incompatible tensor fields $P$ in the new Banach space

$$W^{1,p,r}_0(\text{dev sym Curl}; \Omega, \mathbb{R}^{3\times 3}) = \{ P \in L^p(\Omega; \mathbb{R}^{3\times 3}) | \text{dev sym Curl } P \in L^r(\Omega; \mathbb{R}^{3\times 3}), \text{ dev sym}(P \times \nu) = 0 \text{ on } \partial\Omega \}$$

where

$$r \in [1, \infty), \quad \frac{1}{r} \leq \frac{1}{p} + \frac{1}{3}, \quad r > 1 \quad \text{if } p = \frac{3}{2}.$$ 

Specifically, there exists a constant $c = c(p, \Omega, r) > 0$ such that the inequality

$$\| P \|_{L^p(\Omega; \mathbb{R}^{3\times 3})} \leq c \left( \| \text{sym } P \|_{L^p(\Omega; \mathbb{R}^{3\times 3})} + \| \text{dev sym Curl } P \|_{L^r(\Omega; \mathbb{R}^{3\times 3})} \right)$$

holds for all tensor fields $P \in W^{1,p,r}_0(\text{dev sym Curl}; \Omega, \mathbb{R}^{3\times 3})$. Here, dev $X := X - \frac{1}{3} \text{tr}(X) \mathbb{1}$ denotes the deviatoric (trace-free) part of a $3 \times 3$ matrix $X$ and the boundary condition is understood in a suitable weak sense. This estimate also holds true if the boundary condition is only satisfied on a relatively open, non-empty subset $\Gamma \subset \partial\Omega$. If no boundary conditions are imposed then the estimate holds after taking the quotient with the finite-dimensional space $\mathcal{K}_{S,dSC}$ which is determined by the conditions $\text{sym } P = 0$ and $\text{dev sym Curl } P = 0$. In that case one can replace $\| \text{dev sym Curl } P \|_{L^r(\Omega; \mathbb{R}^{3\times 3})}$ by $\| \text{dev sym Curl } P \|_{W^{1,p}(\Omega; \mathbb{R}^{3\times 3})}$. The new $L^p$-estimate implies a classical Korn’s inequality with weak boundary conditions by choosing $P = Du$ and a deviatoric-symmetric generalization of Poincaré’s inequality by choosing $P = A \in \mathfrak{so}(3)$. The proof relies on a representation of the third derivatives $D^3 P$ in terms of $D^2 \text{dev sym Curl } P$ combined with the Lions lemma.

1 Introduction

1.1 Overview

Korn’s second inequality provides an $L^p$-estimate of a gradient vector field (modulo a constant) in terms of the symmetric part of the derivative. This can be generalized to general fields $P$ if one adds a term in $\text{Curl } P$ on the right-hand side [103,104,127]. For recent refined estimates which involve only the deviatoric part of sym $P$ and $\text{Curl } P$, see [11,102,105].

Here, we show that $P$ can be estimated in dimension $n = 3$ in terms of sym $P$ and $\text{Curl } P$ or even sym $P$ and dev sym $\text{Curl } P$. The difference is that we need to subtract not only constants but also certain affine or quadratic skew-symmetric fields in the kernel of the operators sym $\text{Curl}$ and dev sym $\text{Curl}$, respectively.

To set the stage we recall the notation for the relevant Lie groups used in this paper and their Lie algebras and indicate how our new inequalities relate to (infinitesimal) conformal invariance. We denote the space of $(n \times n)$-matrices by $\mathbb{R}^{n \times n}$ and we denote the groups of proper orthogonal matrices, and matrices with determinant 1 by

$$SO(n) = \{ Q \in \mathbb{R}^{n \times n} | Q^T Q = 1 \}, \quad SL(n) = \{ B \in \mathbb{R}^{n \times n} | \det B = 1 \}. \quad (1.1a)$$

The corresponding Lie algebras of skew-symmetric and trace-free matrices are denoted by

$$\mathfrak{so}(n) = \{ A \in \mathbb{R}^{n \times n} | A^T = -A \}, \quad \mathfrak{sl}(n) = \{ D \in \mathbb{R}^{n \times n} | \text{tr } D = 0 \}. \quad (1.1b)$$

Let $\Omega \subset \mathbb{R}^3$ be open, bounded and simply connected. A $C^1$-map $\varphi : \Omega \to \mathbb{R}^3$ is conformal if its differential preserves the scalar product up to dilations, i.e., if for all $x$ there exist $\lambda(x) \geq 0$ and $Q(x) \in SO(3)$ such that $D\varphi(x) = \lambda(x) Q(x)$. It is well-known that conformal maps are smooth and the non-constant conformal maps form a finite-dimensional manifold. The vector fields in the tangent space of the identity map are called conformal Killing fields (or infinitesimally conformal maps) and are characterized by the condition

$$\text{dev sym } Du = 0. \quad (1.2)$$

In fact the solutions $u$ of (1.2) are certain quadratic polynomials, see (1.10) below for an explicit formula.

In the Cosserat theory, the curvature expression

$$\| \text{dev sym } \text{Curl } A \|^2 \text{ for } A : \Omega \to \mathfrak{so}(3) \quad (1.3a)$$

can be expressed equivalently as

$$\| \text{dev sym } D\text{axl}(A) \|^2. \quad (1.3b)$$

and the latter expression has been termed “conformal curvature”, consistent with (1.2) for $u = \text{axl}(A)$. Therefore, we call the generalized curvature expression

$$\| \text{dev sym } \text{Curl } P \|^2 \quad (1.3c)$$

conformal dislocation energy. Upon restricting $P \in \mathfrak{so}(3)$ we recover (1.3b), see also (1.42).
1.2 The classical Korn’s inequalities

First inequalities of this type were identified by Arthur Korn more than hundred years ago, cf. [87–89], where they were derived for applications in linear elasticity. It is worth mentioning that after his graduation in 1890 Korn studied in Paris under the supervision of Henri Poincaré. For Korn’s biography including his pioneering work in telephotography we refer to [90,106] but also [135, p. 182f].

For $Korn’s$ second inequality (in $L^p$), which does not require boundary conditions:

$$
\|u\|_{W^1, p(\Omega, \mathbb{R}^n)} \leq c \left( \|u\|_{L^p(\Omega, \mathbb{R}^n)} + \|\text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \right) \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^n).
$$

(1.5)

It can be deduced from Korn’s second inequality (in $L^p$), which does not require boundary conditions:

$$
\inf_{\beta \in \mathfrak{X}(n)} \|Du - A\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \leq c \|\text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^n).
$$

(1.6)

For $n \geq 3$ these inequalities can be improved to inequalities which only require the trace-free part of $\text{sym } Du$ on the right hand side. One has

$$
\|Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \leq c \|\text{dev}_n \text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^n),
$$

(1.7)

where $\text{dev}_n X := X - \frac{1}{n} \text{tr}(X) \cdot 1$ denotes the deviatoric (trace-free) part of the square matrix $X \in \mathbb{R}^{n \times n}$. Moreover,

$$
\|u\|_{W^1, p(\Omega, \mathbb{R}^n)} \leq c \left( \|u\|_{L^p(\Omega, \mathbb{R}^n)} + \|\text{dev}_n \text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \right) \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^n),
$$

(1.8)

as well as

$$
\|u - \Pi u\|_{W^1, p(\Omega, \mathbb{R}^{n \times n})} \leq c \|\text{dev}_n \text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{n \times n})} \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^n)
$$

(1.9)

where $\Pi$ is an arbitrary projection from $W^{1,p}(\Omega, \mathbb{R}^n)$ onto the space of conformal Killing vectors (or infinitesimal conformal mappings), i.e., the finite-dimensional kernel of $\text{dev}_n \text{sym } D$, which is given by quadratic polynomials of the form

$$
\varphi_\beta(x) = \langle a, x \rangle x - \frac{1}{2} a \|x\|^2 + A x + \beta x + b, \quad \text{with } A \in \mathfrak{so}(n), a, b \in \mathbb{R}^n \text{ and } \beta \in \mathbb{R},
$$

(1.10)

cf. [37,82,125,137,138,146]. The situation is quite different in the planar case $n = 2$, since the condition $\text{dev}_2 \text{sym } Du \equiv 0$ becomes the system of Cauchy–Riemann equations and the corresponding kernel is infinite-dimensional, so that an adequate quantitative version of the trace-free classical Korn’s inequality does not hold true. However, in [62] it is proved that

$$
\|Du\|_{L^p(\Omega, \mathbb{R}^{2 \times 2})} \leq c \|\text{dev}_2 \text{sym } Du\|_{L^p(\Omega, \mathbb{R}^{2 \times 2})} \quad \forall u \in W^{1,p}(\Omega, \mathbb{R}^2),
$$

(1.11)

In fact, the estimate is also true for functions with vanishing boundary values on a relatively open (non-empty) subset of the boundary.
but this result ceases to be valid if the homogeneous Dirichlet conditions are prescribed only on a part of the boundary, cf. the counterexample in [11, Sect. 6.6].

For the limiting cases \( p = 1 \) and \( p = \infty \) Korn-type inequalities fail, since from the counterexamples traced back in [33,98,112,132] it follows that \( \int_{\Omega} \| \text{sym} \, Du \| \, dx \) does not dominate each of the quantities \( \int_{\Omega} |\partial_i u_j| \, dx \) for any vector field \( u \in W_0^{1,1}(\Omega, \mathbb{R}^n) \). Nevertheless, Poincaré-type inequalities estimating certain integral norms of the deformation \( u \) in terms of the total variation of the symmetric strain tensor \( \text{sym} \, Du \) are still true. For Poincaré-type inequalities for functions of bounded deformation involving only the deviatoric part of the symmetrized gradient we refer to [60].

These Korn inequalities are crucial for a priori estimates in linear elasticity and fluid mechanics, so that they are cornerstones for well-posedness results in linear elasticity (\( L^2 \)-setting) and the Stokes-problem (\( L^p \)-setting), cf. [81] and [29] for a modern elaboration, whereas the trace-free equivalents found applications in micropolar Cosserat-type models [62,82,83,125] and general relativity [37].

The Korn inequalities generalize to many different settings, including the geometrically nonlinear counterpart [58,101], mixed growth conditions [32], incompatible fields (also with dislocations) [11,34,63,69,102–104,115,127] and trace-free infinitesimal strain measures [11,37,62,82,102,105,137,138,146]. For trace-free Korn’s inequalities in pseudo-Euclidean space see [154] and for trace-free Korn inequalities on manifolds see [37,80]. It is also possible to consider tangential boundary conditions, cf. [12,13,39,42,143]. Other generalizations are applicable to Orlicz-spaces [18,19,26,59,61] and SBD functions with small jump sets [25,55,56], thin domains [71,77,100,113] as well as the case of non-constant coefficients [92,118,128,136]. Moreover Korn-type inequalities are valid on Hölder and John domains, see [3,40,41,43,84,108] and also the recent monograph [2] which relates those Korn inequalities to the existence of a right inverse of the divergence operator, to the Stokes equations and other inequalities. Piecewise Korn-type inequalities subordinate to a FEM-mesh and involving jumps across element boundaries have also been investigated, see e.g. [21,99]. In the recent paper [147] the authors established a Korn inequality involving the BMO-seminorms which is valid on all bounded domains and with a constant depending only on the dimension. Here we focus on inequalities for general tensor fields.

### 1.3 Korn-type inequalities for incompatible tensor fields

Classical Korn’s inequalities require compatibility, i.e., a gradient \( Du \) (the Jacobian matrix). Generalizations of such estimates to general fields \( P \) then need a control of the distance of \( P \) to a gradient by adding the incompatibility measure (the dislocation density tensor) \( \text{Curl} \, P \). The matrix \( \text{Curl} \) operation is to be understood as row-wise application of the classical curl to vectors. Even though the usual \( \text{Curl} \) operation on \( \mathbb{R}^3 \) has a natural extension to all dimensions, the case \( n = 3 \) deserves our special attention, not only from the viewpoint of modeling but also since the matrix \( \text{Curl} \) then returns a square matrix in three dimensions. As direct generalization of Korn’s first inequality (1.4) we have for all \( P \in W_0^{1,p}(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \)

\[
\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{sym} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{Curl} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right),
\]

(1.11)

cf. [127] for \( p = 2 \) and [103] for all \( p > 1 \). Furthermore, the version (1.6) generalizes to

\[
\inf_{\tilde{A} \in S^0(3)} \| P - \tilde{A} \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{sym} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{Curl} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right)
\]

(1.12)
for all \( P \in W^{1,p}(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \), cf. [103]. These estimates also hold true in all dimensions \( n \geq 2 \) with an adequate understanding of the matrix Curl, [104]. However, in two dimensions even stronger estimates hold true, cf. [63] and its nonlinear counterpart in [115], so especially, for fields \( P \in L^1(\Omega, \mathbb{R}^{2 \times 2}) \) with Curl \( P \in L^1(\Omega, \mathbb{R}^2) \) it follows that \( P \in L^2(\Omega, \mathbb{R}^{2 \times 2}) \) and

\[
\| P \|_{L^2(\Omega, \mathbb{R}^{2 \times 2})} \leq c \left( \| \text{sym} \, P \|_{L^2(\Omega, \mathbb{R}^{2 \times 2})} + \| \text{Curl} \, P \|_{L^1(\Omega, \mathbb{R}^2)} \right) \quad (1.13)
\]

under the normalization condition \( \int_{\Omega} \text{skew} \, P \, dx = 0 \), cf. [63]. However, this is essentially a result for the divergence, since \( \text{Div} \) is a rotated Curl in two dimensions. Indeed, the authors of [63] make use of the fact that a vector field \( u \in L^1(\Omega, \mathbb{R}^2) \) satisfying \( \text{div} \, u \in H^{-2}(\Omega) \) belongs to \( H^{-1}(\Omega) \) with

\[
\| u \|_{H^{-1}(\Omega, \mathbb{R}^2)} \leq c \left( \| u \|_{L^1(\Omega, \mathbb{R}^2)} + \| \text{div} \, u \|_{H^{-2}(\Omega)} \right) \quad (1.14)
\]

which follows from [22]. For the geometrically nonlinear counterpart of (1.13) in a mixed-growth setting in two dimensions we refer the reader to [67] and higher-dimensional analogues can be found in [34,93].

Improvements of the Korn inequalities for incompatible tensor fields (1.11) and (1.12) towards the trace-free cases are also valid. For all \( P \in W^{1,p}_0(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \), where

\[
W^{1,p}_0(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) := \{ P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{Curl} \, P \in L^p(\Omega, \mathbb{R}^{3 \times 3}), P \times \nu = 0 \text{ on } \partial \Omega \}
\]

one has

\[
\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{dev} \, \text{sym} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev} \, \text{Curl} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right),
\]

(1.16) cf. [11] for \( p = 2 \) and [102] for all \( p > 1 \). Moreover, we have

\[
\inf_{T \in K_{dS,dC}} \| P - T \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{dev} \, \text{sym} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev} \, \text{Curl} \, P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right)
\]

(1.17) for all \( P \in W^{1,p}(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \), cf. [102], where the kernel on the right-hand side is given by

\[
K_{dS,dC} = \{ T : \Omega \to \mathbb{R}^{3 \times 3} \mid T(x) = \text{Anti} \left( A x + \beta x + b \right) + \left( [\text{axl} \, \widetilde{A}, x] + \gamma \right) \|, \]

\[
\widetilde{A} \in \mathfrak{s}(\Omega, \mathbb{R}^{3 \times 3}), b \in \mathbb{R}^{3 \times 3}, \beta, \gamma \in \mathbb{R} \},
\]

(1.18) where \( \text{Anti} : \mathbb{R}^3 \to \mathfrak{s}(\Omega) \) is the canonical identification (consistent with the vector product) of \( \mathbb{R}^3 \) and the vectorspace of skew-symmetric matrices \( \mathfrak{s}(\Omega) \) and \( \text{axl} : \mathfrak{s}(\Omega) \to \mathbb{R}^3 \) is its inverse. The appearance of the \( \text{dev} \, \text{Curl} \) operator on the right hand side would suggest to extend the Banach space \( W^{1,p}(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \) to \( p \)-integrable tensor fields \( P \) with \( p \)-integrable \( \text{dev} \, \text{Curl} \, P \), but this would not be a new space. Indeed, in [102] the authors showed that for all \( P \in \mathcal{D}'(\Omega, \mathbb{R}^{3 \times 3}) \) and all \( m \in \mathbb{Z} \) one has

\[
\text{Curl} \, P \in W^{m,p}(\Omega, \mathbb{R}^{3 \times 3}) \iff \text{dev} \, \text{Curl} \, P \in W^{m,p}(\Omega, \mathbb{R}^{3 \times 3}).
\]

(1.19)

\footnote{The Babuška-Aziz theorem implies that over a planar Lipschitz domain \( \Omega \subset \mathbb{R}^2 \) it holds

\[
\| Du \|_{L^2(\Omega, \mathbb{R}^{2 \times 2})} \leq c \| \text{div} \, u \|_{L^2(\Omega, \mathbb{R})}
\]

for all \( u \in H^1_0(\Omega, \mathbb{R}^2) \) such that \( \int_{\Omega} \text{div} \, u \, dx = 0 \), cf. [81, Sect. 6].}
Note, that the estimates (1.16) and (1.17) are strictly restricted to the case of three dimensions since the deviatoric operator acts on square matrices and only in the three-dimensional setting the matrix \( \text{Curl} \) operator returns again a square matrix. On the other hand, the corresponding weaker estimates in terms of \( \|\text{dev}_{\text{n}} \text{sym} \, P\|_{L^p} + \|\text{Curl} \, P\|_{L^p} \) hold true in all dimensions \( n \geq 3 \), cf. [11] for \( p = 2 \) and [105] for all \( p > 1 \).

For compatible \( P = \text{Du} \) we get back from (1.11), (1.12), (1.16) and (1.17) the corresponding classical Korn inequalities. Recently, Gmeineder and Spector [69] extended inequality (1.11) to the case where \( \text{sym} \, P \) is generalized to any linear operator \( A(P) \) such that \( A(\text{Du}) \) is a first order elliptic operator, thus including also one result of [102] with \( \text{dev} \, \text{sym} \, P \).

The objective of the present paper is to further improve on estimate (1.11) by showing that it already suffices to consider the symmetric or even the trace-free symmetric part of the \( \text{Curl} \). More precisely, for all \( P \in W^{1, p}_{0, r} (\text{dev} \, \text{sym} \, \text{Curl}; \, \Omega, \mathbb{R}^{3 \times 3}) \) where

\[
W^{1, p, r}_{0} (\text{dev} \, \text{sym} \, \text{Curl}; \, \Omega, \mathbb{R}^{3 \times 3}) := \{ P \in L^{p}(\Omega; \mathbb{R}^{3 \times 3}) | \text{dev} \, \text{sym} \, \text{Curl} \, P \in L^{r}(\Omega; \mathbb{R}^{3 \times 3}), \text{dev} \, \text{sym} \, (P \times v) = 0 \text{ on } \partial \Omega \}
\]

and

\[
r \in [1, \infty), \quad \frac{1}{r} \leq \frac{1}{p} + \frac{1}{3}, \quad r > 1 \text{ if } p = \frac{3}{2}\]

there exists a constant \( c = c(p, \Omega, r) > 0 \) such that one has

\[
\| P \|_{L^{p}(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{sym} \, P \|_{L^{p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev} \, \text{sym} \, \text{Curl} \, P \|_{L^{r}(\Omega, \mathbb{R}^{3 \times 3})} \right). \tag{1.20}
\]

If no boundary conditions are imposed then we show

\[
\inf_{T \in K_{S, dSC}} \| P - T \|_{L^{p}(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{sym} \, P \|_{L^{p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev} \, \text{sym} \, \text{Curl} \, P \|_{L^{r}(\Omega, \mathbb{R}^{3 \times 3})} \right), \tag{1.21}
\]

where the kernel is given by

\[
K_{S, dSC} = \left\{ T : \Omega \rightarrow \mathbb{R}^{3 \times 3} \mid T(x) = \text{Anti} \left( \tilde{A} x + \beta x + b + (d, x) \, x - \frac{1}{2} d \| x \|^2 \right) \right\},
\]

\[
\tilde{A} \in \mathfrak{so}(3), \quad b, d \in \mathbb{R}^{3}, \quad \beta \in \mathbb{R}. \tag{1.22}
\]

**Remark 1.1** The right-hand side of (1.20) provides a norm on smooth, compactly supported functions \( P \in C_{0}^{\infty}(\Omega, \mathbb{R}^{3 \times 3}) \). Indeed, \( \text{sym} \, P \equiv 0 \) implies \( P = A \in C_{0}^{\infty}(\Omega, \mathfrak{so}(3)) \), so that by Nye’s formula (1.27) the condition \( \text{dev} \, \text{sym} \, \text{Curl} \, A \equiv 0 \) reads already \( \text{dev} \, \text{sym} \, \text{Du} \equiv 0 \) with \( a := \text{axl} \, A \in C_{0}^{\infty}(\Omega, \mathbb{R}^{3}) \), where \( \text{axl} : \mathfrak{so}(3) \rightarrow \mathbb{R}^{3} \) associates to a skew-symmetric matrix \( A \in \mathfrak{so}(3) \) the vector \( \text{axl} \, A := (-A_{23}, A_{13}, -A_{12})^{T} \). The trace-free Korn’s inequality (1.7) then gives \( \text{Da} \equiv 0 \). Hence, \( a = \text{axl} \, A \) is a constant vector field, \( P = A \) is a constant skew-symmetric matrix field, and with the boundary condition we obtain \( P \equiv 0 \).

**Remark 1.2** On the other hand, there are no such estimates in terms of

\[
\| \text{dev} \, P \| + \| \text{sym} \, \text{Curl} \, P \|, \quad \| \text{dev} \, \text{sym} \, P \| + \| \text{sym} \, \text{Curl} \, P \| \quad \text{or} \quad \| \text{dev} \, \text{sym} \, P \| + \| \text{dev} \, \text{sym} \, \text{Curl} \, P \|
\]

due to the example \( P = \zeta \cdot \mathbb{1} \) for which \( \text{Curl} \, P = -\text{Anti}(\nabla \zeta) \), so that the corresponding right-hand sides would vanish, since here we have \( \text{dev} \, P = \text{dev} \, \text{sym} \, P = 0 \) and also \( \text{sym} \, \text{Curl} \, P = \text{dev} \, \text{sym} \, \text{Curl} \, P = 0 \).
1.4 Proof ideas for Korn inequalities

There exist many different proofs of the classical Korn’s inequalities, cf. the discussions in [5, 14, 23, 28, 38, 49–51, 57, 70, 78, 79, 85, 86, 127, 129, 134, 140, 149–151] as well as [29, Sect. 6.15] and the references contained therein. A rather concise and elegant argument, see [39, 44, 64, 68] and also advocated by Ciarlet and his coworkers [27–31] uses the Lions lemma resp. Neˇcas estimate, the compact embedding \( W^{1,p} \subset \subset L^p \) and the well-known representation of the second distributional derivatives of the displacement \( u \) by a linear combination of the first derivatives of the symmetrized gradient \( D u \), namely

\[
\partial_i \partial_j u_k = \partial_j (\text{sym} \, D u)_{ik} + \partial_i (\text{sym} \, D u)_{jk} - \partial_k (\text{sym} \, D u)_{ij},
\]

(1.24a)

i.e.

\[
D^2 u = L (D \, \text{sym} \, D u) \text{ with a constant coefficient linear operator } L.
\]

(1.24b)

Also the trace-free Korn’s inequalities can be deduced in such a way, relying on the “higher order” analogues of the differential relation (1.24):

\[
D \Delta u = L (D^2 \, \text{dev}_n \, \text{sym} \, D u),
\]

(1.25)

cf. [37] for the case \( p = 2 \) and [146] for all \( p > 1 \).

The first and the last author used a similar reasoning in their series of papers [102–105] to obtain the Korn inequalities for incompatible tensor fields mentioned above. In particular, the gradient of a skew-symmetric matrix field \( A \) can be expressed as linear combination of the entries of the matrix Curl:

\[
DA = L (\text{Curl} \, A),
\]

(1.26)

which in three dimensions reads exactly as Nye’s formula [130, Eq. (7)]:

\[
\text{Curl} \, A = \text{tr}(D \, \text{axl} \, A) \, 1 - (D \, \text{axl} \, A)^T, \quad \text{resp.} \quad D \, \text{axl} \, A = \frac{1}{2} (\text{tr}[\text{Curl} \, A]) \, 1 - (\text{Curl} \, A)^T.
\]

(1.27)

Furthermore, the second derivatives of a skew-symmetric matrix field \( A \) are given by linear combinations of the entries of the derivative of the deviatoric matrix Curl:

\[
D^2 A = L (D \, \text{dev} \, \text{Curl} \, A)
\]

(1.28)

which was used in the proof of the trace-free case [102]. The expression (1.27)1 admits a counterpart on the group of orthogonal matrices \( O(3) \) and even in higher spatial dimensions, see e.g. [126]. Note in passing, that the representation of the kernel of sym \( D u \equiv 0 \) can either be deduced from (1.24) or (1.27) and yields the class \( \text{RM} \) of infinitesimal rigid motions

\[
\text{RM} := \{ \tilde{A} \, x + b \mid \tilde{A} \in \mathfrak{so}(3), b \in \mathbb{R}^3 \}.
\]

(1.29)

Indeed, assuming sym \( D u \equiv 0 \)

- (1.24) implies that \( D^2 u \equiv 0 \), so that \( u \) has to be affine with \( u \in \text{RM} \), equivalently,
- since \( Du = A(x) \) with a skew-symmetric matrix field \( A \), we obtain \( \text{Curl} \, A = \text{Curl} \, Du \equiv 0 \), so that by (1.27) we deduce \( \text{Daxl} \, A \equiv 0 \) and hence \( A \equiv \text{const} \), i.e., again \( u \in \text{RM} \).

Summarizing, the following differential relations connecting higher order derivatives have been used in the distributional sense for
- classical Korn: \( D^2 u = L(D \text{sym } D u) \) cf. [30,44,64]
- trace-free classical Korn: \( D \Delta u = L(D^2 \text{dev}_v \text{sym } D u) \) cf. [37,146]
- incompatible Korn: \( D A = L(\text{Curl } A) \) cf. [103,104]
- trace-free incompatible Korn: \( D^2 A = L(D \text{dev Curl } A) \) cf. [102]
- incompatible Korn: \( D^2 (A + \zeta \cdot 1) = L(D \text{Curl } (A + \zeta \cdot 1)) \) cf. [102,105]
- symmetric incompatible Korn: \( D^2 A = L(D \text{sym Curl } A) \) present paper
- conformally invariant incompatible Korn: \( D^3 A = L(D^2 \text{dev sym Curl } A) \)

\[ D^2 (A + \zeta \cdot 1) = L(D \text{Curl } (A + \zeta \cdot 1)) \] cf. [102,105]

\[ D^3 (A + \zeta \cdot 1) = L(D^2 \text{dev Curl } (A + \zeta \cdot 1)) \] cf. [102]

\[ \text{denoting by } u \text{ a displacement vector field, by } A \text{ a skew-symmetric tensor field, by } \zeta \text{ a scalar field and by } L \text{ a corresponding linear operator with constant coefficients. Moreover, we have by [102]} \]

\[ \text{by } \int \Omega W(Du, P, \text{Curl } P) + \langle f, u \rangle \, dx, \text{ such that } (u, P) \in H^1(\Omega) \times H(\text{Curl}), \]

where the energy \( W \) is defined as

\[ W = \frac{1}{2} \langle \mathcal{C}_e \text{ sym } (Du - P), \text{sym } (Du - P) \rangle_{\mathbb{R}^{3 \times 3}} + \frac{1}{2} \langle \mathcal{C}_{\text{micro}} \text{ sym } P, \text{ sym } P \rangle_{\mathbb{R}^{3 \times 3}} + \frac{1}{2} \langle \mathcal{C}_c \text{ skew } (Du - P), \text{skew } (Du - P) \rangle_{\mathbb{R}^{3 \times 3}} + \frac{\mu L_c^2}{2} \langle L \text{ Curl } P, \text{ Curl } P \rangle_{\mathbb{R}^{3 \times 3}}. \]

\[ (1.31) \]

Here, \( \mathcal{C}_e, \mathcal{C}_{\text{micro}} : \text{Sym}(3) \to \text{Sym}(3) \) are classical 4th order elasticity tensors, \( \mathcal{C}_c : \mathfrak{so}(3) \to \mathfrak{so}(3) \) is a 4th order rotational coupling tensor, \( L_c \geq 0 \) is a characteristic length scale, \( \mu \) is a typical effective shear modulus and \( \mathbb{L} : \mathbb{R}^{3 \times 3} \to \mathbb{R}^{3 \times 3} \). The associated Euler–Lagrange equations read

\[ \text{Div} \left[ \mathcal{C}_e \text{ sym } (Du - P) + \mathcal{C}_c \text{ skew } (Du - P) \right] = f, \]

\[ \mathcal{C}_e \text{ sym } (Du - P) + \mathcal{C}_c \text{ skew } (Du - P) - \mathcal{C}_{\text{micro}} \text{ sym } P - \mu L_c^2 \text{ Curl}[\mathbb{L} \text{ Curl } P] = 0. \]

\[ (1.32) \]
The generalized moment balance (1.32)$_2$ can be seen as a tensorial Maxwell problem due to the \( \text{Curl}(L \text{Curl } P) \) operation, cf. [20]. The most general quadratic representation of the curvature energy is given by

\[
\langle L \text{Curl } P, \text{Curl } P \rangle \qquad (1.33)
\]

where \( L : \mathbb{R}^{3 \times 3} \rightarrow \mathbb{R}^{3 \times 3} \) is a non-standard fourth order tensor with 45 independent entries acting on the non-symmetric second order tensor \( \text{Curl } P \in \mathbb{R}^{3 \times 3} \). Since \( \text{Curl } P \) transforms as a second order tensor under rotations of the coordinate system, cf. [116,119], assuming a certain degree of anisotropy allows one to reduce the complexity of \( L \). Notably, the most general isotropic expression of the curvature energy is given by

\[
\alpha_1 \| \text{dev sym Curl } P \|^2 + \alpha_2 \| \text{skew Curl } P \|^2 + \frac{\alpha_3}{3} \text{tr}^2 (\text{Curl } P),
\]

with three free parameters \( \alpha_1, \alpha_2, \alpha_3 \in \mathbb{R}^+ \). Here we have used the orthogonal decomposition of \( \mathbb{R}^{3 \times 3} \) into orthogonal pieces, namely

\[
\mathbb{R}^{3 \times 3} = [sl(3) \cap \text{Sym}(3)] \oplus so(3) \oplus \mathbb{R} \cdot 1 \quad (1.35a)
\]

so that for any square matrix \( X \in \mathbb{R}^{3 \times 3} \) we have

\[
X = \text{dev sym } X + \text{skew } X + \frac{1}{3} \text{tr}(X) \cdot \mathbb{1},
\]

(1.35b)

where \( \text{dev sym}, \text{skew}, \text{tr} \) are orthogonal projections on the vector space \( sl(3) \cap \text{Sym}(3) \) of symmetric trace free matrices, the space \( so(3) \) of skew-symmetric matrices, and the space \( \mathbb{R} \cdot 1 \) of spherical tensors, respectively.

In order to reduce complexity in the model one might be tempted to replace (1.33) with

\[
[\hat{L} \text{ sym Curl } P, \text{sym Curl } P]
\]

(1.36)

where \( \hat{L} : \text{Sym}(3) \rightarrow \text{Sym}(3) \) is now a classical positive definite fourth order elasticity tensor, whose representation for all anisotropy classes is completely known. A weak formulation of the static problem

\[
\text{Div } \left[ \mathcal{C}_e \text{ sym } (Du - P) + \mathcal{C}_e \text{ skew } (Du - P) \right] = f,
\]

\[
\mathcal{C}_e \text{ sym } (Du - P) + \mathcal{C}_e \text{ skew } (Du - P) - \mathcal{C}_\text{micro} \text{ sym } P - \mu \, L^2 \, \text{Curl[\hat{L} \text{ sym Curl } P]} = 0,
\]

(1.37)

is naturally formulated in the space \( H(\text{sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) := \{ P \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{sym Curl } P \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \} \) and our new result shows that this problem is well-posed for a suitable prescription of tangential boundary data. Returning to (1.34), the problem may be even further “relaxed” by requiring only to control

\[
\| \text{dev sym Curl } P \|^2.
\]

(1.38)

In this case, the natural space to consider is the Hilbert space \( H(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) := \{ P \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{dev sym Curl } P \in L^2(\Omega, \mathbb{R}^{3 \times 3}) \} \) and our result (1.20) implies that the weak formulation is still well-posed.

**Remark 1.3 (Nothing new in plane strain)** Note, that due to the structure of the three-dimensional matrix \( \text{Curl operator in plain strain} \), i.e., assuming that

\[
\begin{pmatrix}
\hat{P}_{11}(x,y) & \hat{P}_{12}(x,y) & 0 \\
\hat{P}_{21}(x,y) & \hat{P}_{22}(x,y) & 0 \\
0 & 0 & 0
\end{pmatrix}, \quad \text{Curl } \hat{P} = \begin{pmatrix} 0 & 0 & * \\
0 & 0 & * \\
0 & 0 & 0 \end{pmatrix}
\]

(1.39)
the operation \( \text{sym} \) or \( \text{dev sym} \) is not leaving the classical \( H(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \) space, since

\[
\| \text{dev}_3 \text{sym} \text{Curl} \hat{P} \|^2 = \| \text{sym} \text{Curl} \hat{P} \|^2 = \frac{1}{2} \| \text{Curl} \hat{P} \|^2.
\] (1.40)

Hence, new properties to be discovered are strictly three-dimensional in nature.

1.5.2 Cosserat model with weakest curvature energy—conformally invariant curvature

The use of the dislocation density tensor \( \text{Curl} \ P \) in the relaxed micromorphic model allows a smooth transition in the modeling to the classical linear Cosserat model. Indeed, letting formally \( C_{\text{micro}} \to \infty \) in the relaxed micromorphic model (1.31), i.e., assuming \( P = A \in \text{so}(3) \) is skew-symmetric, the (isotropic) elastic Cosserat free energy can be written as

\[
\int_{\Omega} \mu \| \text{sym} \text{D}_u \|^2 + \mu_c \| \text{skew}(\text{D}_u - A) \|^2 + \frac{\lambda}{2} \text{tr}^2(\text{D}_u) \\
+ \alpha_1 \| \text{dev sym} \text{Curl} A \|^2 + \alpha_2 \| \text{skew Curl} A \|^2 + \frac{\alpha_3}{3} \text{tr}^2(\text{Curl} A) \, d\mathbf{x} \to \min.
\] (1.41)

In [123,124] it has been shown that choosing \( \alpha_1 > 0, \alpha_2 = \alpha_3 = 0 \) is mandatory for offering \textit{bounded stiffness in bending and torsion} for arbitrary small specimen. This corresponds to the \textit{conformally invariant} curvature case

\[
\| \text{dev sym} \text{Curl} A \|^2 = \| \text{dev sym} \text{D axl}(A) \|^2.
\] (1.42)

Well-posedness results are then based on the trace-free Korn’s inequality [123].

Finally, letting the Cosserat couple modulus \( \mu_c \to \infty \) in (1.41), one obtains the so-called \textit{modified} indeterminate couple stress model [66,125]

\[
\int_{\Omega} \mu \| \text{sym} \text{D}_u \|^2 + \frac{\lambda}{2} \text{tr}^2(\text{D}_u) + \alpha_1 \| \text{dev sym} \text{D curl} u \|^2 \, d\mathbf{x} \to \min.
\] (1.43)

In [125] this curvature energy has been obtained by a passage from a discrete model to a continuum modeling, invoking a “micro-randomness” assumption, which introduces an additional invariance property beyond isotropy.

1.5.3 Application to gradient plasticity with plastic spin

Experiments with differently sized specimens have revealed a pronounced size-effect in elasto-plastic transformations [52,73–75] which cannot be described with classical phenomenological elasto-plasticity models. For the sake of simplicity we assume in the following the additive decomposition of the displacement gradient \( \text{D}_u \) into non-symmetric elastic (recoverable) and non-symmetric plastic (permanent) distortions \( e \) and \( P \), respectively:

\[
\text{D}_u = e + P, \quad e := \text{sym} \text{D}_u = \text{sym} e + \text{sym} P = \varepsilon_e + \varepsilon_p.
\] (1.44)

\[\text{tr} (\text{sym D curl } u) = \text{tr} (\text{D curl } u) = \text{div} \text{ curl } u \equiv 0.\]
under the side condition of plastic incompressibility \( \text{tr}(P) = \text{tr}(\varepsilon_p) \equiv 0 \). A simplified framework for size-independent plasticity can be sketched, based on the introduction of the total free energy, which consist of elastic contributions and local hardening

\[
W(Du, P) = \int_{\Omega} \left( \langle C_e \text{ sym}(Du - P), \text{ sym}(Du - P) \rangle_{\mathbb{R}^{3 \times 3}} + \langle C_{\text{hard}} \text{ sym} P, \text{ sym} P \rangle_{\mathbb{R}^{3 \times 3}} + \langle f, u \rangle \right) \, dx
\]

elastically stored energy

\[
= \int_{\Omega} \langle C_e (\varepsilon - \varepsilon_p), (\varepsilon - \varepsilon_p) \rangle_{\mathbb{R}^{3 \times 3}} + \langle C_{\text{hard}} \varepsilon_p, \varepsilon_p \rangle + \langle f, u \rangle \, dx,
\]

(1.45)

where \( C_e, C_{\text{hard}} \) are classical positive definite fourth order tensors acting on symmetric arguments. We are working here in a phenomenological modeling context. A variational approach to single crystals with dislocations, different from our presented phenomenological viewpoint, has been explored in [144,145] based on [114]. Our term \( \langle C_{\text{hard}} \text{ sym} P, \text{ sym} P \rangle \) gives rise to the usual Prager-type backstress term (linear kinematic hardening) which appears ubiquitous in the literature. The appearance of symmetric hardening arguments to trace-free symmetric arguments, the increment \( \dot{P} \) is determined to be trace-free symmetric and (1.47) can be therefore recast as

\[
\dot{\varepsilon}_p = \mathcal{F}(C_e (\varepsilon - \varepsilon_p) - C_{\text{hard}} \varepsilon_p), \quad \text{tr}(\varepsilon_p) = 0.
\]

(1.48)

In order to extend the modeling framework to incorporate size-dependence, let us focus on the introduction of energetic length scales. In this case, one augments the total energy (1.45) by some terms involving space derivatives of the plastic distortion \( P \) or the plastic strain \( \varepsilon_p := \text{sym} \, P \), for simplicity

\[
||DP||^2 \quad \text{or} \quad ||D\varepsilon_p||^2.
\]

(1.49)

Accordingly, based on (1.49), the evolution law (1.47) needs to be adapted to

\[
\dot{P} = \mathcal{F}(-DPW(Du, P) = \mathcal{F}(C_e \text{ sym}(Du - P) - C_{\text{hard}} \text{ sym} P + \Delta P)
\]

(1.50)

and suitable boundary conditions for the plastic distortion \( P \), here Dirichlet clamping \( P|_{\partial\Omega} \equiv 0 \), cf. [76]. For initial condition \( P(0) \in \text{Sym}(3) \) (1.50) can again be recast into

\[
\dot{\varepsilon}_p = \mathcal{F}(C_e (\varepsilon - \varepsilon_p) - C_{\text{hard}} \varepsilon_p + \Delta \varepsilon_p), \quad \varepsilon_p|_{\partial\Omega} = 0.
\]

(1.51)

Such a model is already able to predict that smaller samples are relatively stiffer. However, the simple gradient terms in (1.49) lack a microscopical justification. However, \( \Delta P \) can be seen as regularization term as in [54]. Since plasticity is mediated by dislocation movements it inspires that a physically more suitable description is given by considering the dislocation

\[ ^4 \text{Laplace component-wise and observe that } \Delta \varepsilon_p \in \text{Sym}(3) \text{ for } \varepsilon_p \in \text{Sym}(3). \]
density tensor \( \text{Curl} \ P \) and, in first approximation, a simple quadratic function thereof to replace (1.49). Hence, the total stored energy can be written

\[
\int_{\Omega} \left( \langle \text{C} \text{e} \ sym \ (Du - P), \ sym \ (Du - P) \rangle + \langle \text{C} \text{hard} \ sym \ P, \ sym \ P \rangle + \langle \text{C} \text{url} \ P, \text{Curl} \ P \rangle + (f, u) \ dx \right).
\]  

(1.52)

Since Curl is self-adjoint with suitable tangential boundary conditions \( P \times \nu|_{\partial\Omega} = 0 \), the evolution law turns into

\[
\dot{P} = \mathcal{F}(\text{C} \text{e} \ sym(Du - P) - \text{C} \text{hard} \ sym \ P - \text{Curl} \text{Curl} P).
\]  

(1.53)

Note that (1.53) is necessarily an evolution for a non-symmetric plastic distortion \( P \) since the contribution Curl Curl \( P \) does not have any symmetry properties. Such models are called gradient plasticity models with plastic spin or distortion gradient plasticity, cf. [45–48,110, 115,119,139,155].

A closer look at (1.52) reveals that the energy provides a uniform control over

\[
\langle \text{C} \text{hard} \ sym \ P, \ sym \ P \rangle + \|\text{Curl} \ P\|^2 \geq c \left( \|\text{sym} \ P\|^2 + \|\text{Curl} \ P\|^2 \right)
\]  

(1.54)

where \( \text{C} \text{hard} \) is assumed to be positive definite. That the right-hand side of (1.54) provides a norm on smooth, compactly supported functions \( P \in C^\infty_0(\Omega, \mathbb{R}^{3 \times 3}) \) was first noted in [119]. Indeed, sym \( P \equiv 0 \) implies \( P = A \in C^\infty_0(\Omega, \text{so}(3)) \), so that using Nye’s formula (1.27) we deduce from Curl \( A \equiv 0 \) that \( \text{Daxl} A \equiv 0 \). Hence, axl \( A \) is a constant vector field, \( P = A \) is a constant skew-symmetric matrix field, and with the boundary condition we obtain \( P \equiv 0 \). Thus, controlling the plastic strain sym \( P \) in \( L^2 \) and the dislocation density tensor Curl \( P \) in \( L^2 \), together with suitable tangential boundary conditions\(^5\) \( P \times \nu = 0 \) on \( \partial\Omega \) one controls the full plastic distortion \( P \in L^2 \). The result led to a sequel of well-posedness results in gradient plasticity with plastic spin in \( H(\text{Curl}) \), cf. [45–48,119].

However, choosing a simple quadratic energy in \( \text{Curl} \ P \) in (1.52) is, for many situations, not suitable. A major scientific question is therefore, how to replace \( \|\text{Curl} \ P\|^2 \) in order to capture important physical features. Let us write \( G(\text{Curl} \ P) \) for this extension. Experimental evidence suggests to use \( G \) with sub-quadratic growth and where the behavior at zero can be differentiable or not. Indeed, in [155] it is argued to consider the one-homogeneous expression \( G(\text{Curl} \ P) = |\|\text{Curl} \ P\| | \) or \( G(\text{Curl} \ P) = \|\text{Curl} \ P\| \cdot \log\|\text{Curl} \ P\| \), see also [35,131,133].

It is furthermore possible to extract some geometrical information from the dislocation density tensor (on the mesoscale). The indices \( i \) and \( j \) of \( (\text{Curl} \ P)_{ij} \) determine the orientation of the Burger’s vector and the dislocation line, respectively. The diagonal components of \( \text{Curl} \ P \) describe screw dislocations and the off-diagonal components describe edge dislocations. For an overview on dislocations in the framework of different types of generalized continua we refer the reader to [1,95,97] and the references therein. Lazar [94,96], see also [121], has used the decomposition of the dislocation density tensor into \( \text{SO}(3) \)-irreducible pieces

\[
\text{Curl} \ P = \text{dev} \ sym \ \text{Curl} \ P + \text{skew} \ \text{Curl} \ P + \frac{1}{3} \text{tr} (\text{Curl} \ P) \cdot 1
\]  

(1.55)

i.e., the orthogonal decomposition (1.35). So, the axitor corresponds to the sum of all possible screw dislocations, the trator to “skew-symmetric” edge dislocations and the tensor describes

---

\(^5\) In the context of gradient plasticity, the boundary conditions \( P \times \nu = 0 \) postulates “no flux of the Burgers vector across the boundary surface” and is referred to as “micro-hard”, cf. [75].
Fig. 1 Orthogonal decomposition and infinitesimal conformal mappings, see (1.10)

a combination of “symmetric” edge-dislocations and single screw-dislocations, cf. [121]. In addition, for compatible $X = Du$ the decomposition (1.35) reads

$$Du = \underbrace{\text{dev sym } Du}_{\text{shear, anti-conformal part, shape-change}} + \underbrace{\text{skew } Du}_{\frac{1}{2} \text{ Anti } (\text{curl } u) \text{ rotation}} + \underbrace{\frac{1}{3} \text{ tr } (Du) \cdot 1.}_{\text{volumetric part, no shape change}}$$

The introduced nomenclature coming from the fact that dev sym $Du = 0$ implies that $u = \varphi_C$ is an infinitesimal conformal mapping, see (1.10)\(^6\) and Fig. 1.

For improved transparency in the physical modeling, we may now assume an additively decomposed ansatz for $\mathcal{G}$:

$$\mathcal{G}(\text{Curl } P) = \mathcal{G}(\text{dev sym } \text{Curl } P + \text{skew } \text{Curl } P + \frac{1}{3} \text{ tr } (\text{Curl } P) \cdot 1)$$

$$= \mathcal{G}_1 (\text{dev sym } \text{Curl } P) + \mathcal{G}_2 (\text{skew } \text{Curl } P) + \mathcal{G}_3 (\text{tr } (\text{Curl } P) \cdot 1)$$

$$= \alpha_1 \| \text{dev sym } \text{Curl } P \|^q_1 + \alpha_2 \| \text{skew } \text{Curl } P \|^q_2 + \frac{\alpha_3}{3} | \text{tr } (\text{Curl } P) |^q_3$$

where in the last step we considered a simple isotropic example. Our novel result (1.20) shows that under the conditions $\alpha_1 > 0$, $\alpha_2 = \alpha_3 \geq 0$, $q_1 > 1$ one can control the plastic distortion $P$ in $L^{q_1}$.

1.5.4 Incompatible linear elasticity

Instead of the classical linear elasticity problem

$$\int_\Omega \langle \text{C}_c \text{ sym } Du, \text{ sym } Du \rangle + \left\langle \text{Div } Gu \right\rangle_{\mathbb{R}^3} dx \rightarrow \min_{u \in H^1(\Omega, \mathbb{R}^3)} u$$

that is

$$\text{Div } \text{C}_c \text{ sym } Du = \text{Div } G, \quad u|_{\Gamma} = \tilde{u} \in H^1(\Omega, \mathbb{R}^3),$$

\(^6\) Note, that besides the divergence and the curl of a vector field also the term dev sym $Du$ has a physical interpretation, namely as the shear, since for “a cube of moving fluid, the shear [of the velocity of that fluid] represents the rate at which each side is deviating from a square, and the nature of that deviation”, cf. [141] where the authors also make use of the “natural” decomposition (1.56), cf. [141, Eq. (6)].

\(^7\) $\text{div } (G^T u) = \langle \text{Div } G, u \rangle_{\mathbb{R}^3} + \langle G, Du \rangle_{\mathbb{R}^{3 \times 3}}$, to fix notation.
we may consider the corresponding incompatible nonlinear elasticity problem
\[
\int_{\Omega} \langle C_e \text{ sym } e, \text{ sym } e \rangle - \langle G, e \rangle + \mu L_e^r \|\text{dev sym Curl } e\| r \, dx \\
\rightarrow \min \ e \in W^{1,2, r} (\text{dev sym Curl } \Omega, \mathbb{R}^{3 \times 3}),
\]
(1.60a)
in other words the strong form of the second order Euler–Lagrange equations formally reads
\[
C_e \text{ sym } e + r \mu L_e^r \text{ Curl} \left( \frac{\text{dev sym Curl } e}{\|\text{dev sym Curl } e\| r \to 2} \right) = G, \quad \text{tr}(C_e \text{ sym } e) = \text{tr}(G)^8,
\]
(1.60b)
under the (consistent) symmetrized tangential boundary condition
\[
\text{dev sym}(e \times v) \big| \Gamma = \text{dev sym}(D\tilde{u} \times v)
\]
(1.60c)
where \(1 < r \leq 2\), \(\tilde{u} \in H^1(\Omega, \mathbb{R}^3)\) and \(G \in H_0^1(\Omega, \mathbb{R}^{3 \times 3})\) are prescribed and \(v\) is the outward unit vector field to \(\partial \Omega\). According to our Theorem 3.5, the solution to (1.60) is unique with respect to the non-symmetric elastic distortion \(e \in W^{1,2, r} (\text{dev sym Curl } \Omega, \mathbb{R}^{3 \times 3})\). Note that for \(0 < r \leq 2\) it holds \(W^{1,2, r} (\text{dev sym Curl } \Omega, \mathbb{R}^{3 \times 3}) \subsetneqq W^{1,2} (\Omega, \mathbb{R}^{3 \times 3})\). The formulation (1.60) might therefore be useful in problems with fracture. Furthermore, the stored energy in (1.60) is always bounded above by the corresponding energy in (1.58) for the compatible case. Replacing \(e = Du\) and taking the divergence, recovers (1.59).1

In the same spirit, in [10] the authors have considered the non-variational second-order problem
\[
C_e \text{ sym } e + 2\mu L_e^2 \text{ inc}(\text{sym } e) = G, \quad \text{inc}(\text{sym } e) v = 0 \quad \text{on } \partial \Omega,
\]
(1.61)
which also looks for a “relaxation” of linear elasticity and determines a unique solution \(\text{sym } e \in L^2(\Omega), \text{inc} (\text{sym } e) \in L^2(\Omega)\), where \(\text{inc } P := \text{Curl}(\text{Curl } P)^T\) and further properties of the inc operator will be discussed below. Replacing \(\text{sym } e = \text{sym } Du\) and taking the divergence would also recover (1.59).1

2 Notations and technical preliminaries

Let \(n \geq 2\). For vectors \(a, b \in \mathbb{R}^n\) we consider the scalar product \(\langle a, b \rangle := \sum_{i=1}^n a_i b_i \in \mathbb{R}\), the (squared) norm \(\|a\|^2 := \langle a, a \rangle\) and the dyadic product \(a \otimes b := (a_i b_j)_{i,j=1,...,n} \in \mathbb{R}^{n \times n}\). Similarly, the scalar product for matrices \(P, Q \in \mathbb{R}^{n \times n}\) is given by \(\langle P, Q \rangle := \sum_{i,j=1}^n P_{ij} Q_{ij} \in \mathbb{R}\) and the (squared) Frobenius-norm by \(\|P\|^2 := \langle P, P \rangle\). Moreover, \(P^T := (P_{ji})_{i,j=1,...,n}\) stands for the transposition of the matrix \(P = (P_{ij})_{i,j=1,...,n}\).

We make use of the orthogonal decomposition of the latter into the symmetric part \(\text{sym } P := \frac{1}{2} \left( P + P^T \right)\) and the skew-symmetric part \(\text{skew } P := \frac{1}{2} \left( P - P^T \right)\). We denote by \(sl(n) := \{ X \in \mathbb{R}^{n \times n} \mid \text{tr}(X) = 0 \}\) the Lie-algebra of trace-free matrices, with \(\text{Sym}(n) := \{ X \in \mathbb{R}^{n \times n} \mid X^T = X \}\) and by \(so(n) := \{ A \in \mathbb{R}^{n \times n} \mid A^T = -A \}\) the Lie-Algebra of skew-symmetric matrices. For the identity matrix we write \(1\), so that the trace of a squared matrix \(P\) is \(\text{tr } P := \langle P, 1 \rangle\). The deviatoric (trace-free) part of \(P\) is given by \(\text{dev}_P := P - \frac{1}{n} \text{tr}(P) \cdot 1\) and in three dimensions we will suppress its index, i.e., we write dev instead of \(\text{dev}_3\).

8 Since \(\text{tr}(\text{Curl } S) = 0\) for \(S \in \text{Sym}(3)\).
By $\mathcal{D}'(\Omega)$ we denote the space of distributions on a bounded Lipschitz domain $\Omega \subset \mathbb{R}^n$ and by $W^{-k, p'}(\Omega)$ the dual space of $W^{1, p}(\Omega)$, where $p' = \frac{p}{p-1}$ is the dual Hölder exponent to $p$.

2.1 The three-dimensional case

In $\mathbb{R}^3$ we further make use of the vector product $\times: \mathbb{R}^3 \times \mathbb{R}^3 \to \mathbb{R}^3$. For a fixed vector $a \in \mathbb{R}^3$ the cross product $a \times b$ is linear in the second component, so that there exists a unique matrix $\text{Anti}(a)$ such that

$$a \times b =: \text{Anti}(a) b \quad \forall b \in \mathbb{R}^3. \quad (2.1)$$

Direct computations show that for $a = (a_1, a_2, a_3)^T$ the matrix $\text{Anti}(a)$ is of the form

$$\text{Anti}(a) = \begin{pmatrix} 0 & -a_3 & a_2 \\ a_3 & 0 & -a_1 \\ -a_2 & a_1 & 0 \end{pmatrix}, \quad (2.2)$$

so that with $\text{Anti} : \mathbb{R}^3 \to \mathfrak{so}(3)$ we have a canonical identification of $\mathbb{R}^3$ with the vector space of skew-symmetric matrices $\mathfrak{so}(3)$. This algebraic approach to the cross product facilitates some of the traditional proofs of vector algebra, cf. [72,107,142,153]. Indeed, also the notations $T_a$, $W(a)$ or even $[a]_\times$ are used for $\text{Anti}(a)$, but the latter emphasizes that we deal with a skew-symmetric matrix. Furthermore, the vector product can be written as

$$a \times b = \text{Anti}(a) b = -b \times a = -\text{Anti}(b) a = (a^T \text{Anti}(b))^T \quad \forall a, b \in \mathbb{R}^3. \quad (2.3)$$

The inverse of $\text{Anti}$ will be called axl : $\mathfrak{so}(3) \to \mathbb{R}^3$ and it associates to a skew-symmetric matrix $A \in \mathfrak{so}(3)$ the (axial) vector $\text{axl} A := (-A_{23}, A_{13}, -A_{12})^T$, so that

$$A b = \text{axl}(A) \times b \quad \forall b \in \mathbb{R}^3. \quad (2.4)$$

The identification of the vector product with a suitable matrix product allows us to generalize the vector product in $\mathbb{R}^3$ to a vector product of a vector $b \in \mathbb{R}^3$ and a matrix $P \in \mathbb{R}^{3 \times 3}$ from the left and from the right:

$$b \times P := \text{Anti}(b) P \quad \text{and} \quad P \times b := P \text{Anti}(b), \quad (2.5)$$

Thus, $b \times P$ is given by a column-wise vector multiplication

$$b \times P = \text{Anti}(b) \begin{pmatrix} P e_1 \\ P e_2 \\ P e_3 \end{pmatrix} = \begin{pmatrix} \text{Anti}(b) P e_1 \\ \text{Anti}(b) P e_2 \\ \text{Anti}(b) P e_3 \end{pmatrix}$$

$$= \begin{pmatrix} b \times (P e_1) \\ b \times (P e_2) \\ b \times (P e_3) \end{pmatrix}, \quad (2.6)$$

whereas in $P \times b$ we have a row-wise vector multiplication

$$P \times b = \begin{pmatrix} (P^T e_1)^T \\ (P^T e_2)^T \\ (P^T e_3)^T \end{pmatrix} \text{Anti}(b) = \begin{pmatrix} (P^T e_1)^T \text{Anti}(b) \\ (P^T e_2)^T \text{Anti}(b) \\ (P^T e_3)^T \text{Anti}(b) \end{pmatrix} \quad (\text{2.3})$$

$$= \begin{pmatrix} (P^T e_1) \times b)^T \\ (P^T e_2) \times b)^T \\ (P^T e_3) \times b)^T \end{pmatrix}. \quad (2.7)$$

For the identity matrix we obtain

$$1 \times b = 1 \text{ Anti}(b) = \text{Anti}(b) \quad \forall b \in \mathbb{R}^3. \quad (2.8)$$
Formally, Nye’s formula (1.27) is a consequence of the following algebraic identity:

\[
\text{Anti}(a) \text{ Anti}(b) = (\text{Anti}(a)) \times b = b \otimes a - \langle b, a \rangle \mathbb{I}
\]

\[
= b \otimes a - \text{tr}(b \otimes a) \mathbb{I} \quad \forall a, b \in \mathbb{R}^3
\]

(2.9)

and the second identity (1.27)1 comes from the converse expression

\[
b \otimes a = (\text{Anti}(a)) \times b + \langle b, a \rangle \mathbb{I} = (\text{Anti}(a)) \times b - \frac{1}{2} \text{tr}((\text{Anti}(a)) \times b) \mathbb{I}
\]

(2.10)

where we have used

\[
\text{tr}((\text{Anti}(a)) \times b)) = \text{tr}(\text{Anti}(a) \text{ Anti}(b)) = \langle \text{Anti}(a) \text{ Anti}(b), \mathbb{I} \rangle
\]

\[
= -\langle \text{Anti}(a), \text{ Anti}(b) \rangle \overset{(2.2)}{=} -2 \langle a, b \rangle.
\]

(2.11)

In addition, for all \(b \in \mathbb{R}^3\) we obtain

\[
\text{Anti}(b) \text{ Anti}(b) \overset{(2.5)}{=} \text{Anti}(b) \times b \overset{(2.9)}{=} b \otimes b - \|b\|^2 \mathbb{I},
\]

(2.12)

so that

\[
\text{Anti}(b) \text{ Anti}(b) \text{ Anti}(b) \overset{(2.12)}{=} (b \otimes b - \|b\|^2 \mathbb{I}) \times b = -\|b\|^2 \text{ Anti}(b).
\]

(2.13)

Consequently, for a symmetric matrix \(S\) we have \(\text{tr}(S \times b) = 0\) for any \(b \in \mathbb{R}^3\), since

\[
\text{tr}(S \times b) = \langle S \times b, \mathbb{I} \rangle \overset{(2.5)}{=} \langle \text{Anti}(b) S \text{ Anti}(b), \mathbb{I} \rangle = \left\langle \text{Anti}(b), S^T \right\rangle \overset{S \in \text{Sym}(3)}{=} 0,
\]

(2.14)

and similarly

\[
\text{tr}((S \times b) \times b)^T \times b) = \left(\langle S \times b \rangle \times b \mathbb{I} \right) \overset{(2.5)}{=} \langle \text{Anti}(b) S \text{ Anti}(b), \mathbb{I} \rangle
\]

\[
= -\langle S, \text{ Anti}(b) \text{ Anti}(b) \rangle \overset{(2.13)}{=} \|b\|^2 \langle S, \text{ Anti}(b) \rangle \overset{S \in \text{Sym}(3)}{=} 0.
\]

(2.15)

Furthermore, we can consider the vector multiplication on both sides:

\[
b \times P \times b = \text{Anti}(b) P \text{ Anti}(b).
\]

(2.16)

However, from the viewpoint of application it is more convenient to look at

\[
(P \times b)^T \times b = (P \text{ Anti}(b))^T \text{ Anti}(b) = -\text{ Anti}(b) P^T \text{ Anti}(b) = -b \times P^T \times b.
\]

(2.17)

In particular, for a skew-symmetric matrix \(A \in \mathfrak{so}(3)\) and a symmetric matrix \(S \in \text{Sym}(3)\) we have

\[
(A \times b)^T \times b = b \times A \times b \quad \text{and} \quad (S \times b)^T \times b = -b \times S \times b.
\]

(2.18)

**Observation 2.1** For \(a, b \in \mathbb{R}^3\) we have

\[
\frac{1}{2} \|a\|^2 \|b\|^2 \leq \|\text{dev sym}(\text{Anti}(a) \times b)\|^2 \leq \frac{2}{3} \|a\|^2 \|b\|^2.
\]

(2.19)

---

9 This algebraic relation is already contained in [142, p. 691 (ii)].
\textbf{Proof} Considering the dev sym parts on both sides of (2.9) we obtain
\[
\text{dev sym}(\text{Anti}(a) \times b) \overset{(2.9)}{=} \text{dev sym}(b \otimes a) = \text{sym}(a \otimes b) - \frac{1}{3} \text{tr}(b \otimes a) \cdot \mathbb{1} = \text{sym}(a \otimes b) - \frac{1}{3} \langle a, b \rangle \cdot \mathbb{1}.
\] (2.20)
Since,
\[
\|\text{sym}(a \otimes b)\|^2 = \frac{1}{4} \|a \otimes b + b \otimes a\|^2 = \frac{1}{2} \|a \otimes b\|^2 + \frac{1}{2} \langle a \otimes b, b \otimes a \rangle
\]
\[
= \frac{1}{2} \|a\|^2 \|b\|^2 + \frac{1}{2} \langle a, b \rangle^2,
\] (2.21)
taking the squared norm on both sides of (2.20) we obtain
\[
\|\text{dev sym}(\text{Anti}(a) \times b)\|^2 \overset{(2.20)}{=} \|\text{sym}(a \otimes b)\|^2 + \frac{1}{9} \langle a, b \rangle^2 \|\mathbb{1}\|^2
\]
\[
- \frac{2}{3} \langle a, b \rangle \langle \text{sym}(a \otimes b), \mathbb{1} \rangle
\]
\[
\overset{(2.21)}{=} \frac{1}{2} \|a\|^2 \|b\|^2 + \frac{1}{2} \langle a, b \rangle^2 + \frac{1}{3} \langle a, b \rangle^2 - \frac{2}{3} \langle a, b \rangle^2
\]
\[
= \frac{1}{2} \|a\|^2 \|b\|^2 + \frac{1}{6} \langle a, b \rangle^2.
\] (2.22)
The right-hand side is bounded from above by \(\frac{2}{3} \|a\|^2 \|b\|^2\) and from below by \(\frac{1}{2} \|a\|^2 \|b\|^2\).
These bounds are sharp if \(a\) is parallel to \(b\) and if \(a\) is perpendicular to \(b\), respectively. \(\Box\)

\textbf{Remark 2.2} Due to the identification of skew-symmetric matrices with vectors in \(\mathbb{R}^3\) the relation (2.19) reads also
\[
\frac{1}{8} \|A\|^2 \|\tilde{A}\|^2 \leq \|\text{dev sym}(A \tilde{A})\|^2 \leq \frac{1}{6} \|A\|^2 \|\tilde{A}\|^2 \quad \forall A, \tilde{A} \in so(3).
\] (2.23)
Indeed, setting \(a := axl A\) and \(\tilde{a} := axl \tilde{A}\), we have \(A \tilde{A} = \text{Anti}(a) \times \tilde{a}\), so that the estimate follows from (2.19) in combination with the identities \(\|A\|^2 = 2 \|a\|^2\) and \(\|\tilde{A}\|^2 = 2 \|\tilde{a}\|^2\).
The bounds in (2.23) are sharp. The upper bound is achieved for \(A = \tilde{A}\) and the lower bound is achieved, e.g., for \(A = \text{Anti}(e_1) = e_3 \otimes e_2 - e_2 \otimes e_3\) and \(\tilde{A} = \text{Anti}(e_2) = e_1 \otimes e_3 - e_3 \otimes e_1\).

In [102] we used moreover for \(P \in \mathbb{R}^{3 \times 3}\) and \(b \in \mathbb{R}^3\) the relation
\[
\text{dev}(P \times b) = 0 \iff P \times b = 0.
\] (2.24)
Here, we use a similar equivalence.

\textbf{Observation 2.3} For \(P \in \mathbb{R}^{3 \times 3}\) and \(b \in \mathbb{R}^3\) we have
\[
\text{dev sym}(P \times b) = 0 \iff \text{sym}(P \times b) = 0.
\] (2.25)

\textbf{Remark 2.4} Surely, (2.25) is not equivalent to the condition \(P \times b = 0\), cf. the example in (2.8).

\textbf{Proof of Observation 2.3} We decompose \(P\) into its symmetric and skew-symmetric part, i.e.,
\[
P = S + \text{Anti}(a), \quad \text{for some } S \in \text{Sym}(3), \ a \in \mathbb{R}^3.
\]
and obtain
\[
\text{dev sym} (P \times b) = \text{sym} (P \times b) - \frac{1}{3} \text{tr} (P \times b) \mathbb{I} \overset{(2.14)}{=} \text{sym} (P \times b) - \frac{1}{3} \text{tr} (\text{Anti}(a) \times b) \mathbb{I} \overset{(2.11)}{=} \text{sym} (P \times b) + \frac{2}{3} \langle a, b \rangle \mathbb{I}.
\] (2.26)

Moreover, for any matrix \( P \in \mathbb{R}^{3 \times 3} \) it holds
\[
(P \times b) b \overset{(2.5)}{=} P \text{ Anti}(b) b \overset{(2.3)}{=} P (b \times b) = 0.
\] (2.27)

Thus, we obtain
\[
\langle b, \text{dev sym} (P \times b) \rangle \overset{(2.26)}{=} \left( \langle b, \left( \text{sym} (P \times b) + \frac{2}{3} \langle a, b \rangle \mathbb{I} \right) \rangle \right) \overset{(2.27)}{=} \frac{2}{3} \langle a, b \rangle \| b \|^2.
\] (2.28)

and the statement follows from the identity
\[
\| b \|^2 \text{ sym} (P \times b) \overset{(2.26)}{=} \| b \|^2 \text{ dev sym} (P \times b) - \frac{2}{3} \| b \|^2 \langle a, b \rangle \mathbb{I} \overset{(2.28)}{=} \| b \|^2 \text{ dev sym} (P \times b) - \langle b, \text{dev sym} (P \times b) \rangle \mathbb{I}.
\] (2.29)

Applying the Cauchy–Bunyakovsky–Schwarz inequality on the right-hand side of (2.29) we obtain
\[
\| \text{dev sym} (P \times b) \| \leq \| \text{sym} (P \times b) \| \overset{(2.29)}{\leq} \left( 1 + \sqrt{3} \right) \| \text{dev sym} (P \times b) \|.
\] (2.30)

\[ \square \]

### 2.2 Considerations from vector calculus

The vector differential operator \( \nabla \) behaves algebraically like a vector, so that, formally, the derivative, the divergence and the curl of a vector field \( a \in \mathcal{D}'(\Omega, \mathbb{R}^3) \) can be expressed as
\[
Da = a \otimes \nabla = (\nabla \otimes a)^T, \quad \text{div} \, a = \langle a, \nabla \rangle = \langle Da, 1 \rangle = \text{tr} (Da) \quad \text{and} \quad \text{curl} \, a = a \times (-\nabla) = \nabla \times a.
\] (2.31)

Formally, the Laplace operator behaves like a scalar with \( \Delta = \| \nabla \|^2 \).

More generally, we can use multilinear expressions to define differential operators as follows. Let \( V \) and \( W \) be finite-dimensional vectorspaces and let \( \text{Lin} (V, W) \) denote the space of linear maps from \( V \) to \( W \). Let \( M : \mathbb{R}^d \times \cdots \times \mathbb{R}^d \to \text{Lin} (V, W) \) be a multilinear map and denote by \( M_{i_1 \ldots i_r} := M(e_{i_1}, \ldots, e_{i_r}) \) the coefficients of \( M \) with respect to the standard basis \( e_1, \ldots, e_d \) of \( \mathbb{R}^d \). We define a differential operator \( D_M \) by
\[
D_M = \sum_{i_1 \ldots i_r} M_{i_1 \ldots i_r} \partial_{i_1} \ldots \partial_{i_r}
\]
where each index \( i_j \) runs from 1 to \( d \). Let \( \Omega \in \mathbb{R}^d \) be open. Then \( D_M \) maps a distribution \( f \in \mathcal{D}'(\Omega, V) \) to a distribution \( D_M f \in \mathcal{D}'(\Omega, W) \). The following simple observation allows us to transfer algebraic identities into identities of vector calculus. We have
\[
\forall \, b \in \mathbb{R}^d \quad M(b, \ldots, b) = 0 \iff \forall \, f \in \mathcal{D}'(\Omega, V) \quad D_M f = 0.
\] (2.32)
Indeed, since $\partial_i \partial_j = \partial_j \partial_i$ in the sense of distributions, both assertions are equivalent to the statement that the symmetrized coefficients of $M$ vanish. For example, the algebraic identity $\text{tr}((a \times b) \otimes b) = 0$ for all $a, b \in \mathbb{R}^3$ translates into the identity $\text{div} \text{curl} f = 0$ for all $f \in \mathcal{D}'(\Omega, \mathbb{R}^3)$. Since $M$ is multilinear we often use the notation

$$ M(\nabla, \ldots, \nabla) := \mathcal{D}M $$

With this notation, (2.32) asserts that we can formally compute as if $\nabla$ was a vector in $\mathbb{R}^d$.

Of special interest is the operator curl and its row-wise extension to a matrix-valued operator Curl. Thus, formally,

$$ \text{Curl} P := P \times (-\nabla) = -P \text{ Anti}(\nabla) $$

for $P \in \mathcal{D}'(\Omega, \mathbb{R}^{3 \times 3})$ where the vector product acts row-wise, cf. (2.7). Surely, $\nabla \times P$ or $-\nabla \times P$ would also be interesting candidates to consider, but, among them, only the matrix Curl from (2.34) kills the derivative of a general vector field $a \in \mathcal{D}'(\Omega, \mathbb{R}^3)$, i.e., $\text{Curl} \text{D}a \equiv 0$. For symmetric tensor fields $S \in \mathcal{D}'(\Omega, \text{Sym}(3))$ we obtain by (2.14)

$$ \text{tr} (\text{Curl} S) \equiv 0. $$

Moreover, it holds for $\zeta \in \mathcal{D}'(\Omega, \mathbb{R})$ and $a \in \mathcal{D}'(\Omega, \mathbb{R}^3)$

$$ \text{Curl}(\zeta \cdot \mathbb{I}) = -\text{Anti}(\nabla \zeta) \quad \text{and} \quad \text{Curl} \text{Anti}(a) = \text{div} a \cdot \mathbb{I} - (\text{D}a)^T. $$

Note in passing that in three dimensions the matrix Curl returns again a square matrix. Furthermore, we make use of the incompatibility operator

$$ \text{inc} P := \text{Curl}((\text{Curl} P)^T) = (P \times \nabla)^T \times \nabla \overset{(2.17)}{=} -\nabla \times P^T \times \nabla $$

$$ \overset{=}{=} -\text{Anti}(\nabla) P^T \text{ Anti}(\nabla). $$

The last expression shows, in particular, that the incompatibility operator preserves symmetry:

$$ (\text{inc} P)^T = \text{inc} (P^T), \quad \text{inc} \text{ sym} P = \text{ sym} \text{ inc} P \quad \text{and} \quad \text{inc} \text{ skew} P = \text{ skewinc} P. $$

Moreover, the incompatibility operator annihilates the symmetric displacement gradient since

$$ \text{inc} (\text{sym} \text{D}a) = -\nabla \times \text{sym} \text{D}a \times \nabla \overset{=}{=} -\frac{1}{2} \nabla \times (\nabla \otimes a + a \otimes \nabla) \times \nabla $$

$$ \overset{=}{=} -\frac{1}{2} \left[ (\nabla \times \nabla) \otimes a \times \nabla + \nabla \times a \otimes (\nabla \otimes \nabla) \right] \equiv 0. $$

Note that this formal calculation was already carried out in Lagally’s monograph on vector calculus from 1928 [91, Ziff. 191]. The action of the incompatibility operator on spherical tensors and antisymmetric tensors is given by

$$ \text{inc} (\zeta \cdot \mathbb{I}) = \Delta \zeta \cdot \mathbb{I} - D^2 \zeta \in \text{Sym}(3) \quad \text{and} \quad \text{inc} (\text{Anti}(a)) = -\text{Anti}(\nabla \text{div} a) \in \mathfrak{so}(3), $$

respectively. For symmetric tensor fields $S$ we obtain, formally by (2.15), again

$$ \text{tr} (\text{inc} \text{ Curl} S) \equiv 0. $$
Remark 2.5 The incompatibility operator \( \text{inc} \) occurs in infinitesimal strain dislocation models, e.g., in the modeling of dislocated crystals or in the modeling of elastic materials with dislocations, since the strain cannot be a symmetrized gradient of a vector field as soon as dislocations are present and the notion of incompatibility is at the basis of a new paradigm to describe the inelastic effects, cf. [7–9, 47, 95, 109]. Furthermore, the equation \( \text{inc} \; \text{sym} \; e \equiv 0 \) is equivalent to the \textit{Saint-Venant compatibility condition(s)}\(^{10}\) defining the relation between the displacement vector field \( u \) and the symmetric strain \( \text{sym} \; e \), more precisely:

\[
\text{inc} \; \text{sym} \; e \equiv 0 \iff \text{sym} \; e = \text{sym} \; Du
\]  

(2.42)

in simply connected domains, cf. [4, 109]. For investigations over multiply connected domains see e.g. [65, 152].

2.3 Linear combinations of higher derivatives

Our analysis relies on a number of apparently hitherto unnoticed identities which arise from the interaction of the matrix \text{Curl} operator with the algebraic splitting (1.35):

\[
X = \text{dev sym} \; X + \text{skew} \; X + \frac{1}{3} \text{tr}(X) \cdot \mathbb{1}.
\]

In particular, we have the following identities.

Lemma 2.6 Let \( A \in \mathcal{D}'(\Omega, \mathfrak{so}(3)) \). Then

(a) \text{the entries of} \( D^2 \; A \) \text{are linear combinations of the entries of} \( D \; \text{sym} \; \text{Curl} \; A \).
(b) \text{the entries of} \( D^3 \; A \) \text{are linear combinations of the entries of} \( D^2 \; \text{dev} \; \text{sym} \; \text{Curl} \; A \).

Proof By Nye’s formula (1.27)\(^1\) we have

\[
\text{sym} \; \text{Curl} \; A = \text{tr}(D \; \text{axl} \; A) \mathbb{1} - \text{sym}(D \; \text{axl} \; A).
\]  

(2.43)

Taking the trace on both sides we obtain \( \text{tr}(\text{sym} \; \text{Curl} \; A) = 2 \; \text{tr}(D \; \text{axl} \; A) \) and inserting this identity into (2.43) we get

\[
\text{sym}(D \; \text{axl} \; A) = \frac{1}{2} \text{tr}(\text{sym} \; \text{Curl} \; A) \mathbb{1} - \text{sym} \; \text{Curl} \; A.
\]  

(2.44)

Moreover, by the relation (1.24) used for the proof of the classical Korn’s inequality, we obtain

\[
D^2 \; \text{axl} \; A \overset{(1.24)}{=} L(D \; \text{sym} \; \text{axl} \; A) \overset{(2.44)}{=} L_1(D \; \text{sym} \; \text{Curl} \; A).
\]  

(2.45)

In other words, the entries of \( D^2 \; A \) are linear combinations of the entries of \( D \; \text{sym} \; \text{Curl} \; A \) which establishes part (a).

To prove (b) we make use of the incompatibility operator \( \text{inc} \), since it kills the symmetric displacement gradient, cf. (2.39). Consider now the deviatoric part on both sides of (2.43):

\[
\text{dev} \; \text{sym} \; \text{Curl} \; A = \frac{1}{3} \text{tr}(D \; \text{axl} \; A) \mathbb{1} - \text{sym}(D \; \text{axl} \; A).
\]  

(2.46)

\(^{10}\) Those compatibility conditions can be found in the third “Appendix” §32 p. 597 et seq. of the third edition of the lecture notes \textit{Résistance des corps solides} given by Navier and extended with several notes and appendices by Barré de Saint-Venant and published as \textit{Résumé des Leçons données à l’École des Ponts et Chaussées sur l’Application de la Mécanique}, vol. I, Paris, 1864. Their coordinate-free version are contained in Lagally’s monograph on vector calculus from 1928 [91, Ziff. 191].
Applying inc on both sides, we obtain in view of (2.39) and (2.40):

\[ 3 \text{inc } \text{dev} \text{sym Curl } A = \Delta \text{tr}(\text{Daxl } A) \cdot I - D^2 \text{tr}(\text{Daxl } A) \quad (2.47) \]

or, equivalently,

\[ D^2 \text{tr}(\text{Daxl } A) = \frac{3}{2} \text{tr}(\text{inc } \text{dev} \text{sym Curl } A) \cdot I - 3 \text{inc } \text{dev} \text{sym Curl } A \]

\[ = L_2(D^2 \text{dev} \text{sym Curl } A), \quad (2.48) \]

where we have used that the entries of inc B are, of course, linear combinations of the entries of D^2 B, so that by (2.46) we have

\[ D^2 \text{sym}(\text{Daxl } A) = L_3(D^2 \text{dev} \text{sym Curl } A). \quad (2.49) \]

The conclusion of part (b) then follows using the relation (1.24):

\[ D^3 \text{axl } A \overset{(1.24)}{=} L(D^2 \text{sym } \text{Daxl } A) \overset{(2.49)}{=} L_4(D^2 \text{dev} \text{sym Curl } A). \]

\[ \square \]

The algebraic considerations above provide information on higher derivatives of P in negative Sobolev spaces. To obtain L^p-estimates for P we use the following deep result.

**Theorem 2.7** (Lions lemma and Nečas estimate) Let \( \Omega \subset \mathbb{R}^n \) be a bounded Lipschitz domain. Let \( m \in \mathbb{Z} \) and \( p \in (1, \infty) \). Then \( f \in \mathcal{D}'(\Omega, \mathbb{R}^d) \) and \( Df \in W^{m-1, p}(\Omega, \mathbb{R}^{d \times n}) \) imply \( f \in W^m, p(\Omega, \mathbb{R}^d) \). Moreover,

\[ \| f \|_{W^m, p(\Omega, \mathbb{R}^d)} \leq c \left( \| f \|_{W^{m-1, p}(\Omega, \mathbb{R}^d)} + \| Df \|_{W^{m-1, p}(\Omega, \mathbb{R}^{d \times n})} \right), \quad (2.50) \]

with a constant \( c = c(m, p, n, d, \Omega) > 0 \).

For a proof we refer to [6, Proposition 2.10 and Theorem 2.3] and [15]. However, for our discussions the heart of the matter is the estimate (2.50), see Nečas [117, Théorème 1]. The case \( m = 0 \) is already contained in [24]; for an alternative proof, see [111, Lemma 11.4.1] and [16, Chapter IV] as well as [17] and [39]. For further historical remarks, see the discussions in [5,28] and the references contained therein.

Since we only have information on higher order derivatives of \( P \) we will use the following consequence of Theorem 2.7.

**Corollary 2.8** Let \( \Omega \subset \mathbb{R}^n \) be a bounded Lipschitz domain, \( m \in \mathbb{Z} \) and \( p \in (1, \infty) \). Denote by \( D^k f \) the collection of all distributional derivatives of order \( k \). Then \( f \in \mathcal{D}'(\Omega, \mathbb{R}^d) \) and \( D^k f \in W^{m-k, p}(\Omega, \mathbb{R}^{d \times n^k}) \) imply \( f \in W^m, p(\Omega, \mathbb{R}^d) \). Moreover,

\[ \| f \|_{W^m, p(\Omega, \mathbb{R}^d)} \leq c \left( \| f \|_{W^{m-1, p}(\Omega, \mathbb{R}^d)} + \| D^k f \|_{W^{m-k, p}(\Omega, \mathbb{R}^{d \times n^k})} \right), \quad (2.51) \]

with a constant \( c = c(m, p, n, d, \Omega) > 0 \).

**Proof** The assertion \( f \in W^m, p(\Omega, \mathbb{R}^d) \) and the estimate (2.51) follow by inductive application of Theorem 2.7 to \( D^l f \) with \( l = k - 1, k - 2, \ldots, 0 \). \[ \square \]

**Lemma 2.9** Let \( A \in L^p(\Omega, \mathfrak{so}(3)) \). Then

(a) \( \text{sym Curl } A \equiv 0 \) in the distributional sense if and only if \( A = \text{Anti}(\tilde{A}x + b) \) almost everywhere in \( \Omega \).
(b) dev sym Curl $A \equiv 0$ in the distributional sense if and only if $A = \text{Anti} \left( \tilde{A} x + b + \beta x + \langle d, x \rangle x - \frac{1}{2} d \|x\|^2 \right)$ almost everywhere in $\Omega$

with constant $\tilde{A} \in \mathfrak{so}(3)$, $b, d \in \mathbb{R}^3$ and $\beta, \gamma \in \mathbb{R}$.

**Remark 2.10** It is seen already from the calculations of the kernels that there can not be corresponding Korn type inequalities in terms of $\|\text{dev sym} P\| + \|\text{sym Curl} P\|$ or $\|\text{dev sym} P\| + \|\text{sym Curl} P\|$. The kernels would be infinite-dimensional, since all restricting information on $\zeta$ would get lost. Indeed, we have

$$\text{sym Curl}(A + \zeta \cdot 1) \overset{(1.27)}{=} \text{tr}(\text{Daxl} A) 1 - \text{sym}(\text{Daxl} A)$$

so that $\text{sym Curl}(A + \zeta \cdot 1) \equiv 0$ or $\text{dev sym Curl}(A + \zeta \cdot 1) \equiv 0$ allow $\zeta$ to be arbitrary.

**Remark 2.11** Solutions of Lemma 2.9 have already been partially indicated in the literature, cf. [11,137]. We include their full deduction here for the convenience of the reader.

**Proof of Lemma 2.9** The “if”-parts follow from a direct calculation using Nye’s formula (1.27):

(a) $\text{Curl}(\text{Anti}(\tilde{A} x + b)) = \tilde{A}$,

(b) $D(\text{Anti} \left( \tilde{A} x + b + \beta x + \langle d, x \rangle x - \frac{1}{2} d \|x\|^2 \right)) = \tilde{A} + \beta 1 + \langle d, x \rangle 1 + x \otimes d - d \otimes x = (\beta + \langle d, x \rangle) 1 + \tilde{A} + \text{Anti}(d \times x)$, hence, $\text{Curl}(\text{Anti} \left( \tilde{A} x + b + \beta x + \langle d, x \rangle x - \frac{1}{2} d \|x\|^2 \right)) = 2(\beta + \langle d, x \rangle) 1 + \tilde{A} + \text{Anti}(d \times x)$,

Now, we will focus on the “only if”-directions.

By (2.44) the condition $\text{sym Curl} A \equiv 0$ implies $\text{sym}(\text{Daxl} A) \equiv 0$, so that the usual calculation for Korn’s inequality, cf. (1.24), gives that $\text{Daxl} A$ must be a constant skew-symmetric matrix. Thus,

$$A = \text{Anti}(\tilde{A} x + b)$$

for some $\tilde{A} \in \mathfrak{so}(3)$ and $b \in \mathbb{R}^3$, which establishes (a).

Considering now $\text{dev sym Curl} A \equiv 0$ we obtain by (2.48) that $D^2 \text{tr}(\text{Daxl} A) \equiv 0$.

Hence,

$$\frac{1}{3} \text{tr}(\text{Daxl} A) = \beta + \langle d, x \rangle$$

(2.52)

for some $d \in \mathbb{R}^3$ and $\beta \in \mathbb{R}$. Define $\tilde{a}$ by

$$\tilde{a}(x) = \beta x + \langle d, x \rangle x - \frac{1}{2} d \|x\|^2.$$  

(2.53)

Then

$$D\tilde{a} = \beta 1 + \langle d, x \rangle 1 + x \otimes d - d \otimes x = (\beta + \langle d, x \rangle) 1 + \text{Anti}(d \times x)$$

and

$$\text{sym D} \tilde{a} = (\beta + \langle d, x \rangle) 1.$$  

(2.54)

Thus, by (2.46) we have

$$\text{sym}(D(\text{axl} A - \tilde{a})) \overset{(2.54)}{=} \text{sym}(\text{Daxl} A) - (\beta + \langle d, x \rangle) 1 \overset{(2.46)}{=} \frac{1}{3} \text{tr}(\text{Daxl} A) 1 - (\beta + \langle d, x \rangle) 1 \overset{(2.52)}{=} 0.$$  

\[ \text{Springer} \]
Again, (1.24) gives that $D(axl A - \bar{a})$ must be a constant skew-symmetric matrix and we have

$$axl A = \tilde{A}x + b + \bar{a},$$

for some $\tilde{A} \in \mathfrak{s}\mathfrak{o}(3)$ and $b \in \mathbb{R}^3$, and statement (b) follows from the representation (2.53).

**Remark 2.12** The conclusion of (b) also follows directly from Nye’s formula and is connected to infinitesimal conformal maps. Indeed, we have

$$\text{dev sym Curl Anti}(a) \overset{(1.27)}{=} \text{dev sym Da},$$

so that

$$\text{dev sym Curl Anti}(a) \equiv 0 \iff \text{dev sym Da} \equiv 0 \iff a = \varphi_C,$$

denoting by $\varphi_C$ an infinitesimal conformal map, so that the expression in (b) of Lemma 2.9 follows from the expression for infinitesimal conformal maps (1.10).

### 3 New incompatible Korn type inequalities

**Lemma 3.1** Let $\Omega \subset \mathbb{R}^3$ be a bounded Lipschitz domain, $1 < p < \infty$ and $P \in \mathcal{D}'(\Omega, \mathbb{R}^{3 \times 3})$. Then either of the conditions

(a) $\text{sym } P \in L^p(\Omega, \mathbb{R}^{3 \times 3})$ and $\text{sym Curl } P \in W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})$,

(b) $\text{sym } P \in L^p(\Omega, \mathbb{R}^{3 \times 3})$ and $\text{dev sym Curl } P \in W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})$,

implies $P \in L^p(\Omega, \mathbb{R}^{3 \times 3})$. Moreover, we have the estimates

$$\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{skew } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{sym } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{sym Curl } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} \right),$$

(3.1a)

$$\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{skew } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{sym } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev sym Curl } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} \right),$$

(3.1b)

always with a constant $c = c(p, \Omega) > 0$.

**Remark 3.2** Clearly, condition (b) is weaker than condition (a) and (3.1b) implies (3.1a). Furthermore, (3.1b) implies the estimate

$$\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{skew } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{sym } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{Curl } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} \right),$$

(3.2)

in [103, Lemma 3.1] as well as the estimate

$$\| P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \| \text{skew } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{sym } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \| \text{dev Curl } P \|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} \right),$$

(3.3)
in [102, Lemma 3.6], but not the estimate
\[\|P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left(\|\text{skew} P + \frac{1}{2} \text{tr} P \cdot 1\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{dev sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})}\right) \tag{3.4}\]
in [102, Lemma 3.6] which uses dev sym \( P \) rather than sym \( P \) on the right-hand side. The point is, that we cannot improve (3.1) to an estimate which involves dev sym \( P \) instead of sym \( P \) on the right-hand side, cf. Remark 1.2.

**Proof** By the previous remark it suffices to establish the assertion \( P \in L^p(\Omega; \mathbb{R}^{3 \times 3}) \) under condition (b) and to prove the estimate (3.1b).

We will follow the same line of reasoning as in the proof of [103, Lemma 3.1] and start by considering the orthogonal decomposition
\[P = \text{sym} P + \text{skew} P.\]

To deduce \( \text{skew} P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \) under assumption (b) we consider
\[\|D^2 \text{dev sym Curl skew} P\|_{W^{-3, p}(\Omega, \mathbb{R}^{3 \times 3})} \leq c \|\text{dev sym Curl}(P - \text{sym} P)\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left(\|\text{dev sym Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})}\right) \leq c \left(\|\text{dev sym Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})}\right). \tag{3.5}\]
Hence, \( D^2 \text{dev sym Curl skew} P \in W^{-3, p}(\Omega, \mathbb{R}^{3 \times 3}) \) and it follows from Lemma 2.6 (b) that
\[D^3 \text{skew} P \in W^{-3, p}(\Omega, \mathbb{R}^{3 \times 3}). \tag{3.6}\]

Now, we apply Corollary 2.8 to \( \text{skew} P \) and we deduce that \( \text{skew} P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \) and
\[\|\text{skew} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left(\|\text{skew} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|D^3 \text{skew} P\|_{W^{-3, p}(\Omega, \mathbb{R}^{3 \times 3})}\right) \leq c \left(\|\text{skew} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|D^2 \text{dev sym Curl skew} P\|_{W^{-3, p}(\Omega, \mathbb{R}^{3 \times 3})}\right) \leq c \left(\|\text{skew} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{dev sym Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})}\right). \tag{3.7}\]

The rigidity results follow by eliminating the corresponding first term on the right-hand side of (3.1).

**Theorem 3.3** Let \( \Omega \subset \mathbb{R}^3 \) be a bounded Lipschitz domain and \( 1 < p < \infty \). There exists a constant \( c = c(p, \Omega) > 0 \) such that for all \( P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \)
\[\inf_{T \in K_{S, SC}} \|P - T\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left(\|\text{sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym Curl} P\|_{W^{-1, p}(\Omega, \mathbb{R}^{3 \times 3})}\right). \tag{3.8a}\]
Proof of Theorem 3.3  We first prove the formulae for the kernels $K_{S,SC}$ and $K_{S,dSC}$. If

$$ P \in K_{S,SC} := \{ P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{sym } P = 0 \text{ a.e. and } \text{sym Curl } P = 0 \text{ in the dist. sense} \}, $$

then $P = \text{skew } P$ and $\text{sym Curl } \text{skew } P = 0$. Thus (3.9a) follows by virtue of Lemma 2.9 (a). Similarly, the formula (3.9b) follows from Lemma 2.9 (b).

The estimates (3.8a) and (3.8b) now follow from Lemma 3.1, the fact that the kernels are finite-dimensional and the compactness of the embedding $L^p(\Omega) \hookrightarrow W^{-1,p}(\Omega)$, see, for example, the proofs [102–104] or [29, Theorem 6.15-3] for similar reasoning. For the convenience of the reader we provide the details for the argument for the estimate (3.8a). The proof of (3.8b) is analogous. By $e_1, \ldots, e_M$ we denote a basis of $K_{S,SC}$, and by $\ell_1, \ldots, \ell_M$ we denote the corresponding dual basis of linear functionals on $K_{S,SC}$ which is characterized by the conditions

$$ \ell_\alpha(e_j) := \delta_{\alpha j}. $$

Then, the Hahn-Banach theorem in a normed vector space (see e.g. [29, Theorem 5.9-1]), allows us to extend $\ell_\alpha$ to continuous linear forms - again denoted by $\ell_\alpha$ - on the Banach space $L^p(\Omega, \mathbb{R}^{3 \times 3})$, $1 \leq \alpha \leq M$. Note that

$$ \forall \ T \in K_{S,SC} \quad T = 0 \iff \ell_\alpha(T) = 0 \ \forall \ \alpha \in \{1, \ldots, M\}. $$
We claim that
\[
\|P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \|\text{sym } P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym Curl } P\|_{W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})} + \sum_{\alpha=1}^M |\ell_\alpha(P)| \right).
\]
(3.14)

Indeed, if this inequality is false, there exists a sequence \(P_k \in L^p(\Omega, \mathbb{R}^{3 \times 3})\) with the properties
\[
\|P_k\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} = 1
\]
and
\[
\left( \|\text{sym } P_k\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym Curl } P_k\|_{W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})} + \sum_{\alpha=1}^M |\ell_\alpha(P_k)| \right) < \frac{1}{k}.
\]
Hence, (for a subsequence) \(P_k \to P^*\) in \(L^p(\Omega, \mathbb{R}^{3 \times 3})\) and we have \(\text{sym } P^* \equiv 0\) and \(\text{sym Curl } P^* \equiv 0\) in the distributional sense but also \(\ell_\alpha(P^*) = 0\) for all \(\alpha = 1, \ldots, M\), so that \(P^* \equiv 0\). Since the embedding \(L^p(\Omega, \mathbb{R}^{3 \times 3}) \hookrightarrow W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})\) is compact we get \(\text{skew } P_k \to \text{skew } P^* \equiv 0\) in \(W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})\). Thus, \(P_k \to 0\) in \(W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})\) and this yields to a contradiction with (3.1a). Hence (3.14) holds.

Now consider the projection \(\pi_a : L^p(\Omega, \mathbb{R}^{3 \times 3}) \to K_{S,SC}\) given by
\[
\pi_a(P) := \sum_{j=1}^M \ell_j(P) e_j.
\]
(3.15)

We obtain \(\ell_\alpha(P - \pi_a(P)) = 0\) for all \(1 \leq \alpha \leq M\), so that (3.8a) follows after inserting \(P - \pi_a(P)\) into (3.14):
\[
\inf_{T \in K_{S,SC}} \|P - T\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq \|P - \pi_a(P)\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})}
\]
\[
\leq c \left( \|\text{sym } P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{sym Curl } P\|_{W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})} \right).
\]

Finally, we show that the estimates in Theorem 3.3 can be improved to estimates for \(P\) itself, and not just for \(P - T\), if we impose a natural boundary condition which annihilates the relevant kernels.

We focus on the improvement of (3.8b) because this already implies the improved estimate for (3.8a). For a weak definition of boundary values of certain linear combinations of \(P\) it is not sufficient to assume only dev sym Curl \(P \in W^{-1,p}(\Omega, \mathbb{R}^{3 \times 3})\). Indeed, this condition is satisfied for every \(P \in L^p(\Omega, \mathbb{R}^{3 \times 3})\). We thus consider, for \(p \in (1, \infty)\) and \(r \in [1, \infty)\) the spaces
\[
W^{1,p,r}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) := \{P \in L^p(\Omega, \mathbb{R}^{3 \times 3}) \mid \text{dev sym Curl } P \in L^r(\Omega, \mathbb{R}^{3 \times 3})\}.
\]
(3.16)

Equipped with the norm
\[
\|P\|_{p,r,dSC} := \|P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{dev sym Curl } P\|_{L^r(\Omega, \mathbb{R}^{3 \times 3})}
\]
(3.17)
this space becomes a Banach space. In terms of scaling the natural relation between \(p\) and \(r\) is \(p = r^*\) where \(r^*\) is the Sobolev exponent of \(r\). To properly treat the borderline case \(p = 1^* = \frac{3}{2}\) we make the following assumptions
\[
\frac{1}{r} \leq \frac{1}{p} + \frac{1}{3}, \quad r > 1 \quad \text{if } p = \frac{3}{2}.
\]
(3.18)
We assume that $\Omega \subset \mathbb{R}^3$ is a bounded domain with Lipschitz boundary. To define boundary conditions for certain linear combinations of the components of $P$ in the distributional sense, we first recall that for $q \in (1, \infty)$ the space $C^1(\overline{\Omega})$ is dense in $W^{1,q}(\Omega)$ and there exists a linear bounded and surjective trace operator $\text{Tr}: W^{1,q}(\Omega) \to W^{1-1/q,q}(\partial \Omega)$ which is uniquely characterized by the condition $\text{Tr} f = f|_{\partial \Omega}$ for all $f \in C^1(\overline{\Omega})$. Moreover there exists a linear, bounded extension operator $\text{E}: W^{1-1/q,q}(\partial \Omega) \to W^{1,q}(\Omega)$ with $\text{Tr} \circ \text{E} = \text{id}$. If follows from the divergence theorem and the density of $W^{1,q}(\Omega)$ that for all $i, j = 1, 2, 3$
\[
\int_{\Omega} \partial_i f \, dx = \int_{\partial \Omega} \text{Tr} f \, \nu_i \, d\mathcal{H}^2 \quad \forall f \in W^{1,q}(\Omega) \tag{3.19}
\]
where $\nu$ denotes the outer normal of $\partial \Omega$ (which exist $\mathcal{H}^2$ a.e. on $\partial \Omega$) and $\mathcal{H}^2$ the two-dimensional Hausdorff measure. For $p \in (1, \infty)$ we denote by $p'$ the dual exponent given by $\frac{1}{p} + \frac{1}{p'} = 1$. The dual of the space $W^{1-1/p',p'}(\partial \Omega) = W^{1/p,p}(\partial \Omega)$ is denoted by $W^{-1/p,p}(\partial \Omega)$. In order to introduce a weak definition of the boundary values of $\text{dev}\, \text{sym}\, \text{Curl}$ we assume that $P_x \in W^{1,p}(\Omega)$ satisfies (3.18). Then we can define a bounded map $S: W^{1-p,r}(\text{dev sym Curl}; \Omega; \mathbb{R}^{3 \times 3}) \to W^{-1/p,p}(\partial \Omega; \mathbb{R}^{3 \times 3})$ by
\[
\langle SP, Q \rangle_{\partial \Omega} := \int_{\partial \Omega} \langle \text{dev sym Curl} P, E Q \rangle - \langle P, \text{Curl} \, \text{dev sym E} \rangle \, dx 
\]
$\forall Q \in W^{1/p,p'}(\partial \Omega, \mathbb{R}^{3 \times 3})$. \tag{3.20}
Here the extension operator is applied componentwise. If $a \in C^1(\overline{\Omega}; \mathbb{R}^3)$ and $b \in W^{1,q}(\partial \Omega, \mathbb{R}^3)$ then it follows from (3.19) that
\[
\int_{\Omega} \langle \text{curl} a, b \rangle - \langle a, \text{curl} b \rangle \, dx = \int_{\partial \Omega} \langle a \times (-\nu), \text{Tr} b \rangle \, d\mathcal{H}^2. \tag{3.21}
\]
Using this identity, the fact that $\text{Curl}$ acts row-wise and (2.7), one easily deduces that for $P \in W^{1}(\Omega; \mathbb{R}^{3 \times 3})$ and $Q \in W^{1/p,p'}(\partial \Omega, \mathbb{R}^{3 \times 3})$
\[
\langle SP, Q \rangle_{\partial \Omega} = \int_{\partial \Omega} \langle \text{dev sym}[P \times (-\nu)], Q \rangle \, d\mathcal{H}^2. \tag{3.22}
\]
Thus, for $P \in C^1(\overline{\Omega}; \mathbb{R}^{3 \times 3})$ we have $SP = \text{dev sym}[P \times (-\nu)]$. Let $\Gamma$ be a relatively open subset of $\partial \Omega$. We say that

$SP = 0$ in $\Gamma$ if $\langle SP, Q \rangle = 0 \quad \forall Q \in (W^{1/p,p'} \cap C^0)(\partial \Omega; \mathbb{R}^{3 \times 3})$ with $Q = 0$ on $\partial \Omega \setminus \Gamma$.

Note that $(W^{1/p,p'} \cap C^0)(\partial \Omega)$ is dense in $W^{1/p,p'}(\partial \Omega)$ since it contains $\text{Tr}(C^1(\overline{\Omega}))$. We define
\[
W^{1,p,r}_{0,\Gamma}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) := \{ P \in W^{1,p,r}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) | SP = 0 \text{ in } \Gamma \}. \tag{3.23}
\]
In particular
\[
T \in C^1(\overline{\Omega}; \mathbb{R}^{3 \times 3}) \cap W^{1,p,r}_{0,\Gamma}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3}) \quad \Rightarrow \quad \text{dev sym}[T \times \nu] = 0 \quad \text{on } \Gamma. \tag{3.24}
\]
Since $S$ is continuous, the space $W^{1,p,r}_{0,\Gamma}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3})$ is a closed subspace of $W^{1,p,r}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3 \times 3})$. \hfill $\square$
Theorem 3.5 Let $\Omega \subset \mathbb{R}^3$ be a bounded Lipschitz domain, let $1 < p < \infty$ and assume that $r$ satisfies (3.18). Let $\Gamma \subset \partial\Omega$ be relatively open and non-empty. Then there exists a constant $c = c(p, r, \Omega, \Gamma)$ such that for all $P \in W^{1, p}_0(\Gamma; \mathbb{R}^{3 \times 3})$ we have
\[
\|P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \|\text{sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{dev sym} \text{Curl} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right). \tag{3.25}
\]

Remark 3.6 Conti and Garroni [34] and Gmeineder and Spector [69] have shown that the estimate
\[
\|P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \left( \|\text{sym} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{Curl} P\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \right)
\]
holds also in the borderline case $r = 1$ and $p = \frac{3}{2}$ under the normalization condition $\int_{\Omega} \text{skew} P \, dx = 0$ similar to [63]. We do not know if Theorem 3.5 holds in this borderline case.

To show Theorem 3.5 we use the following simple fact which will be proved after the proof of Theorem 3.5:

Lemma 3.7 Assume that $\Gamma \subset \mathbb{R}^3$ has the following properties
1. $\Gamma$ is not discrete;
2. $\Gamma$ is not contained in a line;
3. $\Gamma$ is not contained in a circle.

Let $A \in \mathfrak{so}(3)$, $b, d \in \mathbb{R}^3$, $\beta \in \mathbb{R}$ and consider the function $f : \mathbb{R}^3 \to \mathbb{R}^3$ given by
\[
f(x) = Ax + \beta x + b + \langle d, x \rangle x - \frac{1}{2} d\|x\|^2.
\]

Then
\[
f = 0 \text{ on } \Gamma \implies A = 0, b = d = 0, \beta = 0. \tag{3.26}
\]

Proof of Theorem 3.5 We first show that
\[
K_{S,dSC} \cap W^{1, p}_0(\Gamma; \mathbb{R}^{3 \times 3}) = \{0\}. \tag{3.27}
\]
Then the assertion will follow by a standard argument from (3.8b) and the fact that $K_{S,dSC}$ is finite-dimensional while $W^{1, p}_0(\Gamma; \mathbb{R}^{3 \times 3})$ is closed.

To show (3.27), let $T \in K_{S,dSC} \cap W^{1, p}_0(\Gamma; \mathbb{R}^{3 \times 3})$. Then $T$ is smooth and thus (3.24) implies that $\text{dev sym}[T \times v] = 0$ on $\Gamma$. Since the elements of $K_{S,dSC}$ are skew-symmetric it follows from Observation 2.1 and the formula for $K_{S,dSC}$ that there exist $\tilde{A} \in \mathfrak{so}(3), b, d \in \mathbb{R}^3$ and $\beta \in \mathbb{R}$ such that
\[
\text{dev sym} T(x) = \tilde{A} x + \beta x + b + \langle d, x \rangle x - \frac{1}{2} d\|x\|^2 = 0 \quad \text{for all } x \in \Gamma.
\]
Now Lemma 3.7 implies that all coefficients vanish and hence $T \equiv 0$. This concludes the proof of (3.27).

Assume now that (3.25) does not hold. Then there exists a sequence $P_k \in W^{1, p}_0(\Gamma; \mathbb{R}^{3 \times 3})$ such that
\[
\|\text{sym} P_k\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} + \|\text{dev sym} \text{Curl} P_k\|_{L^p(\Gamma, \mathbb{R}^{3 \times 3})} \to 0
\]
and
\[
\|P_k\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \to 1.
\]
The assumption (3.18) on r implies that $W^{1, p'}_0(\Omega)$ embeds continuously into $L^r(\Omega)$. Hence $L^r(\Omega)$ embeds continuously into $W^{-1, p}(\Omega)$. Thus it follows from (3.8b) that there exist $T_k \in K_{S,d,SC}$ such that

$$\|P_k - T_k\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \to 0.$$  

In particular, the sequence $T_k$ is bounded in $L^p$ and since $K_{S,d,SC}$ is finite-dimensional, there exists a $T \in K_{S,d,SC}$ and a subsequence such that $T_k \to T$ in $L^p(\Omega, \mathbb{R}^{3 \times 3})$. Thus (for the same subsequence) $P_k \to T$ in $L^p(\Omega, \mathbb{R}^{3 \times 3})$. Moreover dev sym Curl $P_k$ converges to zero in $L^r$ and dev sym Curl $T = 0$. Since $W^{1, p'}_0(\Omega; \mathbb{R}^{3 \times 3})$ is a closed subspace of $W^{1, p'}(\Omega; \mathbb{R}^{3 \times 3})$ it follows that $T \in W^{1, p'}_0(\Omega; \mathbb{R}^{3 \times 3})$. Hence (3.27) implies that $T = 0$ and thus $P_k \to 0$ in $L^p(\Omega, \mathbb{R}^{3 \times 3})$. This contradicts the hypothesis $\|P_k\|_{L^p} = 1$. □

**Remark 3.8** Estimate (3.25) does not hold true in other dimensions, since only in three dimensions the matrix Curl returns a square matrix.

**Proof of Lemma 3.7** Since $\Gamma$ is not discrete there exists $\bar{x} \in \mathbb{R}^3$ and $x_k \in \Gamma \backslash \{\bar{x}\}$ such that $\lim_{k \to \infty} x_k = \bar{x}$. The map $g(x) := f(\bar{x} + x)$ has the same form as $f$ (with different values of the parameters $A$, $b$, $d$, $\beta$). Thus we may assume without loss of generality that $\bar{x} = 0$. Since $f$ is continuous we get $f(0) = 0$ and hence $b = 0$.

Since

$$0 = \langle f(x), x \rangle = \beta \|x\|^2 + \frac{1}{2} \langle d, x \rangle \|x\|^2 \quad \forall x \in \Gamma \backslash \{0\}$$

we deduce that $\beta + \frac{1}{2} \langle d, x \rangle = 0$ for all $x \in \Gamma \backslash \{0\}$. Considering points $x_k \in \Gamma \backslash \{0\}$ with $x_k \to 0$ we see that $\beta = 0$ and

$$\langle d, x \rangle = 0 \quad \forall x \in \Gamma.$$  

If $d = 0$ then $f(x) = Ax$. If $A \neq 0$ then the kernel of $A$ is a line since $A \in \text{so}(3)$. Thus $\Gamma$ would be contained in a line which contradicts our assumption. Hence for $d = 0$ we get $A = 0$ and we are done.

If $d \neq 0$ then $\Gamma$ is contained in the hyperplane perpendicular to $d$. Since $\langle d, f(x) \rangle = 0$ for all $x \in \Gamma$ and $A$ is skew-symmetric we get

$$2 \langle A d, x \rangle + \|d\|^2 \|x\|^2 = 0 \quad \forall x \in \Gamma.$$  

This implies that

$$\left\| x + \frac{1}{\|d\|^2} A d \right\|^2 = \frac{\|A d\|^2}{\|d\|^4} \quad \forall x \in \Gamma.$$  

Since $A$ is skew-symmetric, the vector $A d$ is contained in the plane perpendicular to $d$. It follows that $\Gamma$ is either a point (and hence discrete) or a circle ($x \in \Gamma$ and $A d$ lie in the same hyperplane) with center $-\frac{1}{\|d\|^2} A d$ and radius $\frac{\|A d\|}{\|d\|^2}$ which contradicts our assumption. □

It is well-known, that Korn’s inequality and Poincaré’s inequality are not equivalent, however, due to the presence of the Curl we get back both inequalities from our general result (3.25). Indeed, in the compatible case $P = \text{D} u$ we recover a tangential Korn inequality.

**Corollary 3.9** Let $\Omega \subset \mathbb{R}^3$ be a bounded Lipschitz domain, $1 < p < \infty$ and $\Gamma$ a relatively open non-empty subset in $\partial \Omega$. There exists a constant $c = c(p, \Omega, \Gamma) > 0$ such that for all $u \in W^{1, p}(\Omega, \mathbb{R}^3)$ with $\text{dev sym}(\text{D} u \times v) = 0$ on $\Gamma$ we have

$$\|\text{D} u\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})} \leq c \|\text{sym} \text{D} u\|_{L^p(\Omega, \mathbb{R}^{3 \times 3})}. \quad (3.28)$$  

Springer
This follows from Theorem 3.5 by setting $P = Du$.

**Remark 3.10** This boundary condition is rather weak. If $\Gamma$ is flat, then the condition $\text{dev} \text{ sym} (Du \times \nu)_{\Gamma} = 0$ implies that $u = \alpha x + b$ along $\Gamma$ with $\alpha \in \mathbb{R}$ and $b \in \mathbb{R}^3$, see “Appendix A.1.4”.

For skew-symmetric $P = \text{Anti}(a)$ we recover from (3.25) a Poincaré’s inequality involving only the deviatoric (trace-free) part of the symmetrized gradient. Such a Poincaré-type inequality can also be generalized to functions of bounded deformation, cf. [60].

**Corollary 3.11** Let $\Omega \subset \mathbb{R}^3$ be a bounded Lipschitz domain and $1 < p < \infty$. Set $W_{\Gamma,0}^{1,p}(\Omega, \mathbb{R}^3) := \{ a \in W^{1,p}(\Omega; \mathbb{R}^3) \mid \text{Tr} a = 0 \text{ on } \Gamma \}$. There exists a constant $c = c(p, \Omega, \Gamma) > 0$ such that for all $a \in W_{\Gamma,0}^{1,p}(\Omega, \mathbb{R}^3)$, we have
\[
\|a\|_{L^p(\Omega, \mathbb{R}^3)} \leq c \|\text{dev sym} D a\|_{L^p(\Omega, \mathbb{R}^{3\times3})}.
\]  

**Proof** This follows from Theorem 3.5 by setting $P = \text{Anti}(a)$ and the following observations:
\[
\text{dev sym} (\text{Anti}(a) \times \nu) = 0 \iff a = 0 \text{ on } \Gamma, \quad \text{Curl(\text{Anti}(a)) = L(Da) and the form of } \text{Anti}(a), \text{cf. (2.2)}.
\]

The results of Theorem 3.5, Corollaries 3.9 and 3.11 can be graphically summarized as follows.

4 Comparison of the spaces $W^{1,p}(\text{sym Curl})$ and $W^{1,p}(\text{dev sym Curl})$

Using the linear expression of the entries of $D\text{ Curl} \ P$ in terms of the entries of $D\text{ dev Curl} \ P$ the authors of [102] showed that for all $P \in \mathcal{D}'(\Omega, \mathbb{R}^{3\times3})$ and all $m \in \mathbb{Z}$ one has
\[
\text{Curl} \ P \in W^{m,p}(\Omega, \mathbb{R}^{3\times3}) \iff \text{dev Curl} \ P \in W^{m,p}(\Omega, \mathbb{R}^{3\times3}).
\]  

One might, therefore, wonder whether the spaces $W^{1,p}(\text{dev sym Curl}; \Omega; \mathbb{R}^3)$ := $W^{1,p}(\text{dev sym Curl}; \Omega; \mathbb{R}^3)$ and $W^{1,p}(\text{sym Curl}; \Omega; \mathbb{R}^3)$ are actually identical, where
\[
W^{1,p}(\text{sym Curl}; \Omega; \mathbb{R}^{3\times3}) := \{ P \in L^p(\Omega, \mathbb{R}^{3\times3}) \mid \text{sym Curl} \ P \in L^p(\Omega, \mathbb{R}^{3\times3}) \}.
\]

We first note that clearly $W^{1,p}(\text{sym Curl}; \Omega; \mathbb{R}^{3\times3}) \subset W^{1,p}(\text{dev sym Curl}; \Omega; \mathbb{R}^{3\times3})$ and that the natural norm $\|P\|_{L^p} + \|\text{dev sym Curl} \ P\|_{L^p}$ on $W^{1,p}(\text{dev sym Curl}; \Omega; \mathbb{R}^{3\times3})$ is weaker than the natural norm on $W^{1,p}(\text{sym Curl}; \Omega; \mathbb{R}^{3\times3})$. Thus, in view of the open mapping theorem, the two spaces are identical if and only if the two natural norms are equivalent.
In view of the second estimate in (2.30) (which follows directly form (2.29) by dividing by \(\|b\|^2\)) one might expect that this is really the case. Indeed, using the reasoning in Sect. 2.2, we see that the algebraic identity (2.29) shows that

\[
\Delta \text{sym Curl } P = L(D^2 \text{ dev sym Curl } P) \tag{4.2}
\]

in the sense of distributions. The identity (4.2) yields interior estimates for all compactly contained subsets \(\Omega'\) of \(\Omega\) of the form

\[
\|\text{sym Curl } P\|_{L^p(\Omega')} \leq C(\Omega') (\|\text{dev sym Curl } P\|_{L^p(\Omega)} + \|P\|_{L^p(\Omega)}) \tag{4.3}
\]

but we will see in the proof of Theorem 4.3 assertion 4 below that this is not enough to obtain equivalence of the norm on the full set \(\Omega\) because we do not impose boundary conditions on \(P\).

To illustrate the obstruction to a global estimate, let use consider the following example. Let \(D\) be the unit ball in \(\mathbb{R}^2\) and consider the spaces \(W^{2,2}(D)\) and \(W^{2,2}_\Delta(D) := \{u \in W^{1,2}(D) \mid \Delta u = 0\}\) with norms \(\|u\|_{W^{2,2}} = \|u\|_{L^2(\Omega)} + \|Du\|_{L^2(\Omega)} + \|D^2u\|_{L^2(\Omega)}\) and \(\|u\|_{\Delta} = \|u\|_{L^2(\Omega)} + \|Du\|_{L^2(\Omega)} + \|\Delta u\|_{L^2(\Omega)}\), respectively. Since \(\Delta\) is an elliptic operator, we have interior estimates \(\|u\|_{W^{2,2}(\Omega')} \leq C(\Omega') \|u\|_{\Delta}\), but the norms are not equivalent since for the harmonic functions \(f_k(x) := \Re(e^{k(x_1+i\pi x_2)})\) we get \(\lim_{k \to \infty} \|u\|_{W^{2,2}}/\|u\|_{\Delta} = \infty\). The reason: while the symbol \(\sigma(\xi) = -(\xi_1^2 + \xi_2^2)\) of the operator \(\Delta\) has no non-trivial real zeroes (this is ellipticity), it does have the non-trivial complex zeroes \(\xi_1 = k, \xi_2 = i k\). This allows us to construct the ‘bad’ functions \(f_k\). A similar analysis of the action of the matrix-valued symbols of the operators \(\text{sym Curl}\) and \(\text{dev sym Curl}\) on \(\mathbb{C}^3\) will allow us below to construct maps \(P_k\) which show that the norms \(\|\text{dev sym Curl } P\|_{L^p(\Omega)} + \|P\|_{L^p(\Omega)}\) and \(\|\text{sym Curl } P\|_{L^p(\Omega)} + \|P\|_{L^p(\Omega)}\) are not equivalent if \(\Omega\) is a bounded domain. By contrast, one can use Fourier transform to show that the norms are equivalent for periodic \(P\) or \(P \in L^p(\mathbb{R}^3, \mathbb{R}^{3 \times 3})\), which we show for the convenience of the reader in “Appendix A.2”.

For the latter purposes we start with the following proposition.

**Proposition 4.1** Let \(V\) be a finite-dimensional vector space and denote by \(\text{Lin}(V, V)\) the space of linear maps from \(V\) to \(V\). Let \(\tilde{A}\) and \(\tilde{A}\) be linear maps from \(\mathbb{R}^n\) to \(\text{Lin}(V, V)\). Assume that

\[
\tilde{A}(\xi)a = 0 \quad \forall \xi \in \mathbb{R}^n\setminus\{0\} \quad \forall a \in \ker \tilde{A}(\xi) \tag{4.4}
\]

and

\[
\dim \ker \tilde{A} \quad \text{is constant on } \mathbb{R}^n\setminus\{0\}. \tag{4.5}
\]

Define differential operators by

\[
\mathcal{A} = \tilde{A}(\nabla) := \sum_{j=1}^n \tilde{A}(e_j)\partial_j \quad \text{and} \quad \tilde{\mathcal{A}} = \tilde{\tilde{A}}(\nabla) := \sum_{j=1}^n \tilde{\tilde{A}}(e_j)\partial_j.
\]

Then for each \(p \in (1, \infty)\) there exists a constant \(c = c(p)\) such that

\[
\|\tilde{\mathcal{A}}f\|_{L^p(\mathbb{R}^n, V)} \leq c \|\mathcal{A}f\|_{L^p(\mathbb{R}^n, V)} \quad \forall f \in L^p(\mathbb{R}^n, V) \tag{4.6}
\]

and

\[
\|\tilde{\mathcal{A}}f\|_{L^p(\mathbb{T}^n, V)} \leq c \|\mathcal{A}f\|_{L^p(\mathbb{T}^n, V)} \quad \forall f \in L^p(\mathbb{T}^n, V) \tag{4.7}
\]

in the distributional sense.
Proof This is well-known, cf. e.g. [53, pp. 1362–1365] or [148, Sect. IV.3]. We recall the argument for the convenience of the reader. We focus on (4.6), the proof of (4.7) is analogous. If suffices to show (4.6) for \( f \in C^\infty_c(\mathbb{R}^n, V) \). Then the general case follows by approximation.

We will construct a linear bounded operator \( \mathcal{M} : L^p(\mathbb{R}^n, V) \to L^p(\mathbb{R}^n, V) \) such that

\[
\tilde{A} f = \mathcal{M} A f \quad \forall f \in C^\infty_c(\mathbb{R}^n, V).
\]  

(4.8)

For \( \xi \in \mathbb{R}^n \setminus \{0\} \) we define

\[
\mathbb{P}(\xi) : V \to V \quad \text{as the orthogonal projection onto } \ker A(\xi)
\]  

(4.9)

and we define \( \mathbb{Q}(\xi) : V \to V \) by

\[
\mathbb{Q}(\xi)A(\xi) = \text{Id} - \mathbb{P}(\xi), \quad \mathbb{Q} \equiv 0 \quad \text{on } (\text{range } A(\xi))^\perp.
\]  

(4.10)

It follows from (4.5) that \( \xi \mapsto \mathbb{P}(\xi) \) is smooth and homogeneous of degree zero on \( \mathbb{R}^n \setminus \{0\} \), while \( \xi \mapsto \mathbb{Q}(\xi) \) is smooth and homogeneous of degree \(-1\). For \( \xi \in \mathbb{R}^n \setminus \{0\} \) define

\[
\mathbb{M}(\xi) := \tilde{A}(\xi)\mathbb{Q}(\xi).
\]  

(4.11)

Then \( \mathbb{M} \) is homogeneous of degree zero and smooth on the unit sphere \( S^{n-1} \) of \( \mathbb{R}^n \). For \( f \in C^\infty_c(\mathbb{R}^n, V) \) define

\[
\mathcal{M} f = (\mathcal{F}^{-1}\mathbb{M} \mathcal{F} f
\]  

(4.12)

where \( \mathcal{F} \) denotes the Fourier transform. By the Mikhlin-Hörmander multiplier theorem \( \mathcal{M} \) has a unique extension to a bounded operator on \( L^p(\mathbb{R}^n, V) \). Moreover we have

\[
\mathbb{M}(\xi)A(\xi) = \tilde{A}(\xi)\mathbb{Q}(\xi)A(\xi) = \tilde{A}(\xi) - \tilde{A}(\xi)\mathbb{P}(\xi) = \tilde{A}(\xi).
\]  

(4.13)

Here we used the assumption (4.4) in the last identity. Now (4.8) follows from the definition of \( \mathcal{M} \). \( \square \)

On bounded sets we will make use of the following behavior.

**Proposition 4.2** Let \( \Omega \subset \mathbb{R}^3 \) be bounded, open and non-empty. Let \( z = x_1 + i x_2 \) and let \( q_k(x) = z^k \). Then

\[
\lim_{k \to \infty} \frac{\|kq_{k-1}\|_{L^p(\Omega, \mathbb{C})}}{\|q_k\|_{L^p(\Omega, \mathbb{C})}} = \infty.
\]

**Proof** For \( \delta > 0 \) define \( U_\delta := \{ x \in \mathbb{R}^3 \mid x_1^2 + x_2^2 < \delta^2 \} \). Since \( |q_{k-1}/q_k| \leq \delta^{-1} \) on \( \Omega \setminus U_\delta \) we have

\[
\lim_{k \to \infty} \frac{\|kq_{k-1}\|_{L^p(\Omega \setminus U_\delta, \mathbb{C})}}{\|q_k\|_{L^p(\Omega \setminus U_\delta, \mathbb{C})}} = \infty.
\]  

(4.14)

Now the assertion follows from the fact that

\[
\lim_{k \to \infty} \frac{\|q_k\|_{L^p(\Omega \setminus U_\delta, \mathbb{C})}}{\|q_k\|_{L^p(\Omega, \mathbb{C})}} = 1
\]

whenever \( \delta > 0 \) is so small that \( \Omega \setminus U_{2\delta} \) has positive measure. \( \square \)

With these preparations in hand we arrive at our final result.
Theorem 4.3  The following assertions hold for $p \in (1, \infty)$.

1. (whole space $\mathbb{R}^3$) There exists a constant $c = c(p)$ such that for $P \in L^p(\mathbb{R}^3, \mathbb{R}^{3 \times 3})$

$$\| \text{sym Curl } P \|_{L^p(\mathbb{R}^3, \mathbb{R}^{3 \times 3})} \leq c \| \text{dev sym Curl } P \|_{L^p(\mathbb{R}^3, \mathbb{R}^{3 \times 3})};$$  \hspace{1cm} (4.15)

2. (periodic functions) if $\mathbb{T}^3 = \mathbb{R}^3/\mathbb{Z}^3$ then for all $P \in L^p(\mathbb{T}^3, \mathbb{R}^{3 \times 3})$

$$\| \text{sym Curl } P \|_{L^p(\mathbb{T}^3, \mathbb{R}^{3 \times 3})} \leq c \| \text{dev sym Curl } P \|_{L^p(\mathbb{T}^3, \mathbb{R}^{3 \times 3})};$$  \hspace{1cm} (4.16)

3. (half-spaces) if $\Omega$ is a half-space then for $P \in L^p(\Omega, \mathbb{R}^{3 \times 3})$ the seminorms $\| \text{sym Curl } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})}$ and $\| \text{dev sym Curl } P \|_{L^p(\Omega, \mathbb{R}^{3 \times 3})}$ are not equivalent;

4. (bounded sets) If $\Omega \subset \mathbb{R}^3$ is a bounded, open, non-empty set then

$$W^{1,p}(\text{sym Curl}; \Omega, \mathbb{R}^3) \neq W^{1,p}(\text{dev sym Curl}; \Omega, \mathbb{R}^3).$$

Notation  In this subsection we use the notation

$$\langle a, b \rangle := \sum_{j=1}^{3} a_j b_j \quad \text{for } a, b \in \mathbb{C}^3.$$  \hspace{1cm} (4.19)

Note that this is different from the usual sesquilinear form $\sum_j a_j \overline{b}_j$ where $\overline{z}$ denotes the complex conjugate of a complex number $z$. In particular $\langle a, a \rangle$ is not nonnegative on $\mathbb{C}^3$.

Proof  The first and second assertion for the whole space and periodic functions follow from the estimate (2.30)

$$\forall \xi \in \mathbb{R}^3 \; \forall \widehat{P} \in \mathbb{R}^{3 \times 3} \; \| \text{sym}(\widehat{P} \times \xi) \| \leq (1 + \sqrt{3}) \| \text{dev sym}(\widehat{P} \times \xi) \|,$$  \hspace{1cm} (4.17)

the fact that $\text{dim}\{ \widehat{P} \; | \; \text{dev sym}(\widehat{P} \times \xi) = 0 \} = 4$ is independent of $\xi$ for $\xi \in \mathbb{R}^3 \setminus \{0\}$ and Proposition 4.1, applied to the operators $\widehat{a}(\xi) P = \text{dev sym}(P \times \xi)$ and $\widehat{a}(\xi) P = \text{sym}(P \times \xi)$.

To prove the third and fourth assertion we first show that

$$\exists \xi \in \mathbb{C}^3 \; \exists \widehat{P} \in \mathbb{C}^{3 \times 3} : \; \text{dev sym}(\widehat{P} \times \xi) = 0 \quad \text{and} \quad \text{sym}(\widehat{P} \times \xi) \neq 0.$$  \hspace{1cm} (4.18)

Then the assertion will follow by standard arguments. One such example is given by

$$\widehat{P} = \begin{pmatrix} 0 & 0 & -1 \\ 0 & 0 & i \\ -i & 0 & 0 \end{pmatrix} \quad \text{and} \quad \xi = \begin{pmatrix} 1 \\ i \\ 0 \end{pmatrix} \Rightarrow \widehat{P} \times \xi = \begin{pmatrix} i & -1 & 0 \\ 1 & i & 0 \\ 0 & 0 & i \end{pmatrix}$$  \hspace{1cm} (4.19a)

so that

$$\text{sym}(\widehat{P} \times \xi) = i \cdot 1 \quad \text{but} \quad \text{dev sym}(\widehat{P} \times \xi) = 0.$$  \hspace{1cm} (4.19b)

Further examples which fulfill (4.18) can be found splitting $\widehat{P}$ into the symmetric and skew-symmetric part: $\widehat{P} = \widehat{S} + \text{Anti}(\widehat{a})$. By (2.26)

$$\text{dev sym}(\widehat{P} \times \xi) = \text{sym}(\widehat{P} \times \xi) + \frac{2}{3} \langle \widehat{a}, \xi \rangle \cdot 1.$$  \hspace{1cm} (4.20)

Thus it suffices to find $\widehat{P} \in \mathbb{C}^{3 \times 3}$ and $\xi \in \mathbb{C}^3$ such that $\text{dev sym}(\widehat{P} \times \xi) = 0$ and $\langle \widehat{a}, \xi \rangle \neq 0$. Indeed, the example in (4.19a) satisfies these conditions.
Now we show that in a half-space the seminorms $\|\text{sym Curl} \cdot\|_{L^p(\Omega,\mathbb{R}^{3\times3})}$ and $\|\text{dev sym Curl} \cdot\|_{L^p(\Omega,\mathbb{R}^{3\times3})}$ are not equivalent. Since the operators dev sym Curl and sym Curl interact naturally with rotations it suffices to consider the half-space

$$\Omega = \{ x \in \mathbb{R}^3 \mid x_1 < 0 \}.$$  

Note that the norms are equivalent for real-valued fields $P$ if and only if they are equivalent for complex-valued fields $P$. Let $\xi$ and $\hat{P}$ be as in (4.19a). For a constant vector $b \in \mathbb{R}^3$ and a scalar function $\xi$ we have $\text{curl}(b \xi) = b \times (-\nabla \xi)$. Since Curl acts row-wise we have for a constant matrix $\hat{P}$ the identity $\text{Curl}(\hat{P} \xi) = -\hat{P} \times \nabla \xi$. Thus for all $k \in \mathbb{N}$

$$\text{Curl}(\hat{P} e^{k(\xi,x)}) = -\hat{P} \times \nabla e^{k(\xi,x)} = -ke^{k(\xi,x)}(\hat{P} \times \xi) \quad (4.21)$$

so that with (4.19b) we have

$$\text{sym Curl}(\hat{P} e^{k(\xi,x)}) = -i k e^{k(\xi,x)} \cdot 1 \quad \text{and} \quad \text{dev sym Curl}(\hat{P} e^{k(\xi,x)}) = 0. \quad (4.22)$$

Let $\eta \in C^\infty_c(B(0,2))$ be a cut-off function such that $\eta = 1$ in $B(0,1)$ and consider the functions

$$P_k(x) = \frac{1}{k} \hat{P} e^{k(\xi,x)} \eta(x). \quad (4.23)$$

Then

$$\text{Curl} P_k(x) = \frac{\eta(x)}{k} \text{Curl}(\hat{P} e^{k(\xi,x)}) - \frac{1}{k} e^{k(\xi,x)} \hat{P} \text{Anti}(\nabla \eta)$$

$$\equiv -e^{k(\xi,x)} \left( \hat{P} \times \xi + \frac{1}{k} \hat{P} \text{Anti}(\nabla \eta) \right) \quad (4.21)$$

and with (4.19b) we obtain

$$\|\text{dev sym Curl} P_k(x)\| \leq C \frac{1}{k} e^{kx_1} \sup \|\nabla \eta\| \quad (4.24a)$$

and

$$\text{sym Curl} P_k = -i e^{kx_1+ikx_2} \cdot 1 \quad \text{in} \; B(0,1). \quad (4.24b)$$

From this we easily conclude that $\|\text{sym Curl} P_k\|_p/\|\text{dev sym Curl} P_k\|_p \to \infty$ which shows claim 3.

Finally, we prove the last assertion 4. Let $\Omega$ be a bounded, open, non-empty set. It suffices to show that in $W^{1,p}(\text{sym Curl}; \Omega, \mathbb{C}^{3\times3})$ the norms $\|\cdot\|_{L^p(\Omega,\mathbb{C}^{3\times3})}$ and $\|\text{dev sym Curl} \cdot\|_{L^p(\Omega,\mathbb{C}^{3\times3})}$ are not equivalent. Indeed, this implies that also in $W^{1,p}(\text{sym Curl}; \Omega, \mathbb{R}^{3\times3})$ the norms $\|\cdot\|_{L^p(\Omega,\mathbb{R}^{3\times3})}$ and $\|\text{dev sym Curl} \cdot\|_{L^p(\Omega,\mathbb{R}^{3\times3})}$ are not equivalent. Thus, since the identity map

$$i : W^{1,p}(\text{sym Curl}; \Omega, \mathbb{R}^{3\times3}) \to W^{1,p}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3\times3})$$

is continuous it then follows from the open mapping theorem that $W^{1,p}(\text{dev sym Curl}; \Omega, \mathbb{R}^{3\times3}) \neq W^{1,p}(\text{sym Curl}; \Omega, \mathbb{R}^{3\times3})$.  

Let $\xi$ and $\hat{P}$ be again as in (4.19a). Set $z = x_1 + ix_2$ and

$$P_i(x) := \hat{P} e^{i(\xi,x)} = \hat{P} e^{iz}. \quad (4.25)$$

Then as in (4.22)

$$\text{dev sym Curl} P_i = 0 \quad (4.26)$$
and
\[ \text{sym Curl } P_t = -i t e^{t z} \cdot 1. \] (4.27)

Let \( Q_k(x) = \hat{P}z^k \). Taking the \( k \)th derivative of (4.26) and (4.27) and evaluating at \( t = 0 \) we get, for all \( k \in \mathbb{N} \),
\[ \text{dev sym Curl } Q_k = 0, \quad \text{sym Curl } Q_k = -i k z^{k-1} \cdot 1. \] (4.28)

It follows from Proposition 4.2 that
\[ \lim_{k \to \infty} \frac{\| \text{sym Curl } Q_k \|_{L^p(\Omega, \mathbb{C}^{3 \times 3})}}{\| Q_k \|_{L^p(\Omega, \mathbb{C}^{3 \times 3})} + \| \text{dev sym Curl } Q_k \|_{L^p(\Omega, \mathbb{C}^{3 \times 3})}} = \infty. \]

This concludes the proof of the theorem. \( \square \)

**Remark 4.4** Assertion 4 of Theorem 4.3 is complemented by the following two strict inclusions:
\[ W^{1, p}(\Omega, \mathbb{R}^{3 \times 3}) \subsetneq W^{1, p}(\text{Curl}; \Omega, \mathbb{R}^{3 \times 3}) \subsetneq W^{1, p}(\text{sym Curl}; \Omega, \mathbb{R}^{3 \times 3}). \] (4.29)

To see that the first inclusion is strict, we may use functions of the form \( P_k = Du_k \) where \( u_k = w(kx) \) and \( w : \mathbb{R}^3 \to \mathbb{R}^3 \) is periodic, to see that the corresponding norms are not equivalent. To see that the second inclusion is strict we can use functions of the form \( P_k(x) = \zeta(kx) \cdot 1 \) where \( \zeta : \mathbb{R}^3 \to \mathbb{R} \) is periodic, and observe that \( \text{sym Curl } P_k = k \text{ sym} (\text{Anti}(\nabla \zeta)(kx)) = 0 \).

A Appendix

A.1 Geometrical interpretation of tangential boundary conditions

A.1.1 The case \( P \times \nu = 0 \) following \[75\]

In this “Appendix” we provide the reader with the development of Gurtin and Needleman \[75\] adapted to our notation. Let \( \nu \in \mathbb{R}^3 \) be a unit vector. For the projection onto the plane perpendicular to \( \nu \) we can consider one of the following matrix representations:

\[
P_{\nu} = 1 - \nu \otimes \nu \quad (2.9) = -\text{Anti}(\nu) \times \nu \quad (2.12) = -\text{Anti}(\nu) \text{Anti}(\nu) = \text{Anti}(\nu)^T \text{Anti}(\nu). \quad (A.1)
\]

The last expression shows directly that the vector product of \( P_{\nu} \) and \( \nu \) commutes:

\[
\nu \times P_{\nu} = -\text{Anti}(\nu) \text{Anti}(\nu) = P_{\nu} \times \nu \quad (2.13) \quad (A.2)
\]

and we have moreover for any \((3 \times 3)\)-matrices \( P \) and \( H \):

\[
\langle P \times \nu, H \rangle = \langle P \text{Anti}(\nu), H \rangle = -\langle P, H \text{Anti}(\nu) \rangle
\]

\[
= -\langle P, H \times \nu \rangle \quad (A.2) \quad \langle P P_{\nu} \text{Anti}(\nu), H \rangle
\]

\[
= -\langle P P_{\nu}, H \times \nu \rangle. \quad (A.3)
\]

and also

\[
\| P P_{\nu} \|^2 = \langle P P_{\nu}, P P_{\nu} \rangle \quad (A.1) \quad \langle P \text{Anti}(\nu) \text{Anti}(\nu), P \text{Anti}(\nu) \text{Anti}(\nu) \rangle
\]

\[
= -\langle P \text{Anti}(\nu), P \text{Anti}(\nu) \text{Anti}(\nu) \text{Anti}(\nu) \rangle \quad (A.4)
\]

\[
\| P \times \nu \|^2 = \langle P \times \nu, P \times \nu \rangle \quad (A.1) \quad \langle P \text{Anti}(\nu), P \text{Anti}(\nu) \rangle = \| P \times \nu \|^2
\]

\[
\| P \|^2 - \langle P, P \rangle = \| P \|^2 - \| P \|^2. \quad (A.5)
\]

Thus, \( P P_{\nu} = 0 \) if and only if \( P \times \nu = 0 \). The latter condition can be tested by applying the scalar product with deviatoric (trace-free) matrices, it holds:

\[
\langle P \times \nu, D \rangle = 0 \quad \forall D \text{ with tr } D = 0 \iff P \times \nu = 0. \quad (A.7)
\]

This implies \( \text{dev}(P \times \nu) = 0 \) if and only if \( P \times \nu = 0 \) and extends, of course, to the case of arbitrary non-zero vector \( \nu \in \mathbb{R}^3 \), cf. also our Observation 2.2 in \[102\] and shows

\[
\|\text{dev}(P \times \nu)\| \leq \| P \times \nu \| \leq C \cdot \|\text{dev}(P \times \nu)\|. \quad (A.8)
\]
To establish (A.7), let $H$ be an arbitrary matrix and consider the trace-free matrix $D := H - \text{tr}(H) v \otimes v$. By the assumption we have
\[
0 = \langle P \times v, D \rangle = \langle P \times v, H - \text{tr}(H) v \otimes v \rangle = \langle P \times v, H \rangle + \text{tr}(H) \langle P, (v \otimes v) \times v \rangle = \langle P \times v, H \rangle.
\]
Since $H$ is arbitrary, it follows $P \times v = 0$.

**A.1.2 The compatible case $Du \times v = 0$**

Let $\Gamma$ be a relatively open (non-empty) connected subset of the boundary $\partial \Omega$ and assume that $P = Du$ is compatible. The condition $Du \times v|_{\Gamma} \equiv 0$ is equivalent to $Du \tau|_{\Gamma} \equiv 0$ which can also be written as $Du \tau|_{\Gamma} \equiv 0$ for all tangential directions on $\Gamma$, meaning that all tangential derivatives of $u$ along $\Gamma$ are vanishing. Thus, $u$ has to be constant along $\Gamma$, since for any curve $\gamma : [0, 1] \to \Gamma$ on $\Gamma$ we have $\frac{d}{ds} u(\gamma(s)) = Du(\gamma(s)) \gamma'(s) = 0$, cf. [68, p. 35].

**A.1.3 The case $\text{sym}(P \times v) = 0$**

If $\text{sym}(P \times v) = 0$, then there exists a vector $a \in \mathbb{R}^3$ so that $P \times v = \text{Anti}(a)$. Hence,
\[
a \times v = \text{Anti}(a) v = (P \times v) v = P \text{Anti}(v) v = P(v \times v) = 0 \quad (A.10)
\]
and $a$ has to be of the form $a = \alpha \cdot v$ with $\alpha \in \mathbb{R}$. Thus we have $P \times v = \alpha \cdot \text{Anti}(v) = \alpha \cdot \mathbb{1} \times v$ and we conclude
\[
\text{sym}(P \times v) = 0 \iff P \times v = \alpha \cdot \text{Anti}(v) \iff (P - \alpha \cdot \mathbb{1}) \times v = 0
\]
\[
\iff (P - \alpha \cdot \mathbb{1}) \times v = 0 \quad \text{for an } \alpha \in \mathbb{R}. \quad (A.11)
\]
In a similar way to (A.7), it follows that
\[
\langle \text{sym}(P \times v), D \rangle = 0 \quad \forall D \text{ with } \text{tr} D = 0 \iff \text{sym}(P \times v) = 0 \quad (A.12)
\]
so that again we deduce that $\text{dev \ sym}(P \times v) = 0$ if and only if $\text{sym}(P \times v) = 0$, cf. our Observation 2.3.

**A.1.4 The compatible case $\text{sym}(Du \times v) = 0$**

Let $\Gamma$ be a relatively open (non-empty) connected subset of the boundary $\partial \Omega$ and assume that $P = Du$ is compatible. By the previous observation the condition $\text{sym}(Du \times v)|_{\Gamma} = 0$ is fulfilled if and only if there exists a function $\xi : \Gamma \to \mathbb{R}$ such that $(Du - \xi \cdot \mathbb{1}) \tau|_{\Gamma} = 0$. If $u = \alpha x + b$, then it is clear that this boundary condition is satisfied. On a flat portion of the boundary we will establish also a converse statement. Indeed, let (after possible rotation) $\Gamma \subseteq \mathbb{R}^2 \times \{0\}$ be simply connected and $\gamma : [0, 1] \to \Gamma$. By the previous observation we have $\frac{d}{ds} u(\gamma(s)) = Du(\gamma(s)) \gamma'(s) = \xi(\gamma(s)) \gamma'(s)$, so that $u(\gamma(1)) = u(\gamma(0)) + \int_0^1 \xi(\gamma(s)) \gamma'(s) ds$ and for a closed curve $\gamma$ we deduce
\[
0 = \int_0^1 \xi(\gamma(s)) \gamma'(s) ds = \int_0^1 \begin{pmatrix} \langle \xi(\gamma(s)) e_1, \gamma'(s) \rangle \\ \langle \xi(\gamma(s)) e_2, \gamma'(s) \rangle \\ \langle \xi(\gamma(s)) e_3, \gamma'(s) \rangle \end{pmatrix} ds = \int_0^1 \begin{pmatrix} \langle \hat{\xi}(\gamma_1(s), \gamma_2(s)), 0 \rangle, (\gamma_1'(s), \gamma_2'(s)) \end{pmatrix}_{\mathbb{R}^2} ds \quad (A.13)
\]
where in the last step we have used, that $\gamma \subset \mathbb{R}^2 \times \{0\}$ has vanishing third component and we have set $\tilde{\zeta}(x, y) = \zeta(x, y, 0)$. Since (A.13) is valid for all connected curves $\gamma \subset \Gamma \subseteq \mathbb{R}^2 \times \{0\}$ the vector fields $\left(\hat{\zeta}, 0\right)^T$ and $(0, \hat{\zeta})^T$ have to be conservative. Thus,

$$0 = \text{curl}_{2D} \left( \frac{\zeta}{\tilde{\zeta}} \right)_y = -\hat{\zeta}, \quad \text{and} \quad 0 = \text{curl}_{2D} \left( 0 \frac{\tilde{\zeta}}{\zeta} \right) = \hat{\zeta},$$

where $\text{curl}_{2D} \mathbf{v} = v_2, x - v_1, y$, so that we conclude $\zeta = \tilde{\zeta} \equiv \text{const}$ and set $\hat{\zeta}(x, y) = \zeta(x, y, 0)$.

The previous observation imply $\frac{d}{ds} \left[ u(\gamma(s)) - \alpha \gamma(s) \right] \equiv 0$ for all admissible curves $\gamma$ meaning that along $\Gamma$ the function $u$ has to be of a form $u(x, y, 0) = \alpha \cdot (x, y, 0)^T + (b_1, b_2, 0)^T$.

### A.2 Fourier transformation and equivalence of spaces

The Fourier transform of $f$ on $\mathbb{R}^3$ is given by

$$\mathcal{F} f(\xi) = \hat{f}(\xi) = (2\pi)^{-\frac{3}{2}} \int_{\mathbb{R}^3} e^{-i\langle \xi, x \rangle} f(x) \, dx, \quad \xi \in \mathbb{R}^3.$$  \hspace{1cm} (A.15)

If $f$ is sufficiently regular, then $\hat{\partial_j f}(\xi) = i \xi_j \hat{f}(\xi)$. Thus, for a sufficiently regular vector field $v : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ we have

$$\text{curl} \, v(\xi) = i \xi \times \hat{v}(\xi) = i \hat{v}(\xi) \times (-\xi)$$ \hspace{1cm} (A.16)

and for a sufficiently regular matrix field $P : \mathbb{R}^3 \rightarrow \mathbb{R}^{3 \times 3}$ it follows

$$\text{Curl} \, P(\xi) = -i \hat{P}(\xi) \times \xi = -i \hat{P}(\xi) \text{ Anti}(\xi).$$ \hspace{1cm} (A.17)

Consequently,

$$\mathcal{F} \text{sym Curl} \, P(\xi) = -i \text{ sym}(\hat{P}(\xi) \times \xi)$$

and $\mathcal{F} \text{dev sym Curl} \, P(\xi) = -i \text{ dev sym}(\hat{P}(\xi) \times \xi)$. \hspace{1cm} (A.18)

Recall, that by (2.30) we have the estimate

$$\forall \xi \in \mathbb{R}^3 : \| \text{dev sym}(P \times \xi) \| \leq \| \text{sym}(P \times \xi) \| \leq (1 + \sqrt{3}) \| \text{dev sym}(P \times \xi) \|$$ \hspace{1cm} (A.19)

which in regard with (A.18) gives

$$c \| \mathcal{F} \text{dev sym Curl} \, P \|_{L_2(\mathbb{R}^3)} \leq \| \mathcal{F} \text{sym Curl} \, P \|_{L_2(\mathbb{R}^3)} \leq C \| \mathcal{F} \text{dev sym Curl} \, P \|_{L_2(\mathbb{R}^3)}. $$ \hspace{1cm} (A.20)

Since by Plancherel’s theorem the Fourier transformation is an isometry of spaces, i.e. the $L^2$-norm satisfies $\| f \|_{L_2(\mathbb{R}^3)} = \| \hat{f} \|_{L_2(\mathbb{R}^3)}$ we conclude

$$c \| \text{dev sym Curl} \, P \|_{L_2(\mathbb{R}^3, \mathbb{R}^{3 \times 3})} \leq \| \text{sym Curl} \, P \|_{L_2(\mathbb{R}^3, \mathbb{R}^{3 \times 3})} \leq C \| \text{dev sym Curl} \, P \|_{L_2(\mathbb{R}^3, \mathbb{R}^{3 \times 3})}.$$ \hspace{1cm} (A.21)
In other words, \( \text{dev sym Curl } P \in L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3}) \) if and only if \( \text{sym Curl } P \in L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3}) \), thus, establishing the equivalence of spaces without boundary conditions

\[
W^{1,2}(\text{dev sym Curl}; \mathbb{R}^3, \mathbb{R}^{3\times 3}) = W^{1,2}(\text{sym Curl}; \mathbb{R}^3, \mathbb{R}^{3\times 3}),
\]
as well as the norm equivalence

\[
\|P\|_{L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3})} + \|\text{sym Curl } P\|_{L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3})} \\
\leq C(\|P\|_{L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3})} + \|\text{dev sym Curl } P\|_{L^2(\mathbb{R}^3, \mathbb{R}^{3\times 3})}).
\]

Moreover, from the estimate (2.19) it follows that for fixed \( b \neq 0 \) the linear map \( a \mapsto \text{dev sym}(\text{Anti}(a) \times b) \) is invertible. A specific inverse map can be obtained as follows. Set

\[
M := \text{dev sym}(\text{Anti}(a) \times b) = \frac{1}{2} (a \otimes b + b \otimes a) - \frac{1}{3} \langle a, b \rangle \cdot \mathbb{I}.
\]

Thus,

\[
\text{tr } M = 0, \quad M b = \frac{1}{2} \|b\|^2 a + \frac{1}{6} \langle a, b \rangle b, \quad \text{and} \quad \langle Mb, b \rangle = \frac{2}{3} \langle a, b \rangle \|b\|^2
\]

and we have

\[
a = L_b M, \quad \text{where} \quad L_b M := \frac{2}{\|b\|^2} \left( M b - \frac{1}{4} \langle Mb, b \rangle b \right).
\]

Hence, we conclude

\[
\text{skew } P(\xi) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( \text{skew } P(\xi) \times \frac{\xi}{\|\xi\|} \right) \right] \right) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( (\text{skew } P(\xi)) \times \frac{\xi}{\|\xi\|} \right) \right] \right) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( (\tilde{P} - \text{sym } \tilde{P})(\xi) \right) \times \frac{\xi}{\|\xi\|} \right] \right)
\]

\[
= \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \frac{-i}{\|\xi\|} \mathcal{F} \text{dev sym Curl } P(\xi) \right] \right)
\]

\[
- L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( \text{sym } P(\xi) \times \frac{\xi}{\|\xi\|} \right) \right]. \tag{A.18}
\]

Thus, standard multiplier estimates will give \( L^p \) estimates (for \( 1 < p < \infty \)) in the periodic setting and in the whole space \( \mathbb{R}^3 \).

### A.3 Some basic identities

We outline some basic identities which played useful roles in our considerations:

\[
\text{skew } P(\xi) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( \text{skew } P(\xi) \times \frac{\xi}{\|\xi\|} \right) \right] \right) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( (\text{skew } P(\xi)) \times \frac{\xi}{\|\xi\|} \right) \right] \right) = \text{Anti} \left( L_{\xi/\|\xi\|} \left[ \text{dev sym} \left( (\text{skew } P(\xi)) \times \frac{\xi}{\|\xi\|} \right) \right] \right).
\]
The expression in (1) reads in more details

$$(S \times b)^T \times b = -b \times S \times b = -\text{Anti}(b) S \text{ Anti}(b)$$

$$= S(b \otimes b) + (b \otimes b) S - \|b\|^2 S - \text{tr}(S) b \otimes b$$

$$+ (\|b\|^2 \text{ tr}(S) - \langle S, b \otimes b \rangle_{\mathbb{R}^3} \cdot 1, \quad (A.23)$$

so that the formal equivalent for \( \text{inc } S \) has the form

$$\text{inc } S = D \text{ Div } S + (D \text{ Div } S)^T - \Delta S$$

$$- D^2 \text{ tr}(S) + (\Delta \text{ tr}(S) - \text{div Div } S) \cdot 1. \quad (A.24)$$

The expression in (l) reads in more details

$$(a \otimes b) b = \text{tr}(a \otimes b) \quad \text{ scalar product,}$$

$$a \times b = \text{axl}(a \otimes b) \quad \text{ vector product,}$$

$$b \times b = 0,$$

$$\langle a, b \rangle = 0,$$

$$2 \text{ skew}(a \otimes b) = -\text{Anti}(a \times b).$$

(b) \( P b = b, \)

$$\text{ Anti}(a) b = a \times b = -\text{Anti}(b) a,$$

$$A b = (axl A) \times b,$$

$$\langle b \otimes a \rangle b = ||b||^2 a + (a \times b) b,$$

$$P^T b = P \text{ Anti}(b) = -\langle \text{Anti}(b) P^T \rangle^T,$$

$$I \times b = \text{ Anti}(b) \in \mathfrak{so}(3),$$

(e) \( (a \otimes b) b = 0, \)

$$\frac{1}{2} (b \otimes a) b = \text{sym}(a \otimes b) b = -\text{skew}(a \otimes b) b = b \otimes \text{ skew}(a \otimes b),$$

(f) Room's formulae:

$$\langle \text{Anti}(a) \rangle b = b \otimes a - (b, a) \cdot 3,$$

$$A b = b \otimes \text{ axl } A - (b, \text{ axl } A) \cdot 3,$$

$$\langle \text{axl } A \rangle b = (A b)^T = -\frac{1}{2} \text{tr}(A b) \cdot 3,$$

$$\text{tr}(A b) = 2 (\text{axl } A b),$$

$$\langle b \otimes a \rangle b = 0,$$

$$\langle (a \otimes b) b \rangle b = 0,$$

$$\langle \text{sym}(a \otimes b) b \rangle b = 0,$$

$$\langle \text{skew}(a \otimes b) b \rangle b = 0,$$

$$\langle \text{ Anti}(a) \rangle (b \otimes b)^T \times b = -b (a, \text{ Anti}(b) \in \mathfrak{so}(3),$$

(l) \( (S \otimes b)^T \times b = ||b||^2 \text{ tr}(S) - \langle S, b \otimes b \rangle_{\mathbb{R}^3},$$

$$\text{dev}(P \otimes b) = P b + \frac{1}{2} (\text{axl } \text{ skew } P) b, \quad 3,$$

$$\langle P \otimes b \rangle b = (P b)^T \times b = (\text{sym } P \otimes b) b \times b + (\text{skew } P \otimes b) b \times b,$$

$$\text{tr}(S b \otimes b) = 0,$$

$$\langle a \times b, c \rangle = -\langle a, c \times b \rangle,$$

$$\text{dev } \langle a \otimes b \rangle b = 0,$$

$$\text{dev } \langle \text{ Anti}(a) \otimes b \rangle b = 0,$$

$$\text{dev } \langle P \otimes b \rangle b = 0$$

$$\text{dev } \langle \text{sym } P \otimes b \rangle b = 0,$$

$$\text{dev } \langle \text{skew } P \otimes b \rangle b = 0,$$

$$\text{for } a, b \in \mathbb{R}^3, S \in \text{Sym}(3), A \in \mathfrak{so}(3) \text{ and } P \in \mathfrak{d}(\Omega, \mathbb{R}^3).$$
