Abstract. The algebra \( L_{g,n}(H) \) was introduced by Alekseev–Grosse–Schomerus and Buffenoir–Roche and quantizes the character variety of the Riemann surface \( \Sigma_{g,n} \backslash D \) (\( D \) is an open disk). In this article we define a holonomy map in that quantized setting, which associates a tensor with components in \( L_{g,n}(H) \) to tangles in \( (\Sigma_{g,n} \backslash D) \times [0,1] \), generalizing previous works of Buffenoir–Roche and Bullock–Frohman–Kania-Bartoszynska. We show that holonomy behaves well for the stack product and the action of the mapping class group; then we specialize this notion to links in order to define a generalized Wilson loop map. Thanks to the holonomy map, we give a geometric interpretation of the vacuum representation of \( L_{0,g}(H) \) on \( L_{0,g}(H) \). Finally, the general results are applied to the case \( H = U_q(\mathfrak{sl}_2) \) in relation to skein theory and the most important consequence is that the stated skein algebra of a compact oriented surface with just one boundary edge is isomorphic to \( L_{g,n}(U_q(\mathfrak{sl}_2)) \).

Throughout the paper we use a graphical calculus for tensors with coefficients in \( L_{g,n}(H) \) which makes the computations and definitions very intuitive.

1 Introduction

Let \( G \) be a Lie group, usually assumed connected and simply-connected (the most studied example is \( G = \text{SL}_2(\mathbb{C}) \)) and let \( \Sigma_{g,n} \) be the compact oriented surface of genus \( g \) with \( n \) punctures (or equivalently with \( n \) open disks removed). It is well-known that the moduli space of flat \( G \)-connections on \( \Sigma_{g,n} \) can be identified with the \( G \)-character variety \( \text{Hom}(\pi_1(\Sigma_{g,n}),G)/G \); thanks to the identification between a connection and its holonomy on closed curves. The character variety carries a Poisson structure due to Atiyah–Bott [AB83] and Goldman [Gol86]. A good survey of these topics is [Lab13].

There exist several quantizations of the character variety. In this paper we will use the combinatorial quantization, developed in the mid-90s by Alekseev [Ale94], Alekseev–Grosse–Schomerus [AGS95, AGS96] and Buffenoir–Roche [BR95]. The starting point of this approach is the combinatorial description of the Atiyah–Bott–Goldman Poisson structure by Fock–Rosly [FR98], based on classical \( r \)-matrices, and the definition of an algebra \( L_{g,n} \) which quantizes \( \text{Hom}(\pi_1(\Sigma_{g,n} \backslash D),G) \), where \( D \) is an open disk.
More precisely let \( \Sigma^o_{g,n} = \Sigma_{g,n} \setminus D \), \( A_{g,n} = \text{Hom}(\pi_1(\Sigma^o_{g,n}), G) \) and \( \mathbb{C}[A_{g,n}] \) be the corresponding algebra of functions. Since \( \pi_1(\Sigma^o_{g,n}) \) is a free group, any \( \nabla \in A_{g,n} \cong G^{2g+n} \) can be identified with a collection of \( 2g+n \) elements of \( G \)

\[
\nabla = (h_{b_1}, h_{a_1}, \ldots, h_{b_g}, h_{a_g}, h_{m_{g+1}}, \ldots, h_{m_{g+n}}) \in G^{2g+n}
\]

which are the holonomies of the generators \( b_i, a_i, m_i \) of \( \pi_1(\Sigma^o_{g,n}) \). Let \( T : G \to \text{End}_\mathbb{C}(V) \) be a finite dimensional representation of \( G \). Then we define matrices

\[
\begin{align*}
V & B(1), V & A(1), \ldots, V & B(g), V & A(g), V & M(g+1), \ldots, V & M(g+n) \in \mathbb{C}[A_{g,n}] \otimes \text{End}_\mathbb{C}(V)
\end{align*}
\]

with coefficients in \( \mathbb{C}[A_{g,n}] \) as follows

\[
\begin{align*}
V & \left( B(k)^j_i \right)(\nabla) = T^j_i(h_{b_k}), \quad V & \left( A(k)^j_i \right)(\nabla) = T^j_i(h_{a_k}), \quad V & \left( M(k)^j_i \right)(\nabla) = T^j_i(h_{m_k})
\end{align*}
\]

where \( T^j_i \) are the matrix coefficients of \( T \) in some basis. Since \( \mathbb{C}[A_{g,n}] \cong \mathbb{C}[G]^{\otimes(2g+n)} \), the coefficients of the matrices \( B(k), A(k), M(k) \) (with \( V \) running in the set of finite dimensional \( G \)-modules) generate \( \mathbb{C}[A_{g,n}] \) as an algebra. The Fock-Rosly description expresses the Poisson brackets \( \{ B(k)^j_i \}, \{ A(k)^j_i \}, \{ M(k)^j_i \} \) etc in a matrix form thanks to a classical \( r \)-matrix. The idea of combinatorial quantization is to replace the Lie group \( G \) by the quantum group \( U_q(\mathfrak{g}) \) (\( q = e^h \)) and the classical \( r \)-matrix \( r \in \mathfrak{g} \otimes \mathfrak{g} \) by the quantum \( R \)-matrix \( R \in U_q(\mathfrak{g}) \otimes \mathfrak{g} \), modulo non-trivial commutation relations governed by \( R \). This defines an associative non-commutative algebra \( \mathcal{L}_{g,n} \), generated by coefficients \( B(k)^j_i, A(k)^j_i, M(k)^j_i \) (with \( V \) now running in the set of finite dimensional \( U_q(\mathfrak{g}) \)-modules), and such that the commutator of two such matrix coefficients contains the Fock–Rosly Poisson bracket at the order 1 in \( h \). An important feature of \( \mathcal{L}_{g,n} \) is that it is endowed with a \( U_q(\mathfrak{g}) \)-module-algebra structure, which is the quantized version of the action of \( G \) on \( \mathbb{C}[A_{g,n}] \) by conjugation; in particular we have a subalgebra \( \mathcal{L}^{inv}_{g,n} \) of invariant elements, which is the quantized version of the observables \( \mathbb{C}[A_{g,n}]^G \). The definition of \( \mathcal{L}_{g,n} \) is purely algebraic and works for any ribbon Hopf algebra \( H \) instead of \( U_q(\mathfrak{g}) \), hence defining an algebra \( \mathcal{L}_{g,n}(H) \) (see Definition 2.1). In this paper there are no further assumptions on \( H \).

Holonomy and Wilson loops (trace of the holonomy in some representation) are very natural notions in classical gauge theory. Thus an immediate problem is to define the corresponding notions in the quantized setting. This is has been achieved first in [BR96], where they defined a Wilson loop operation for framed links in the thickened surface with values in \( \mathcal{L}^{inv}_{g,n}(H) \); the element associated to a framed link is written as the quantum trace of some matrix with coefficients in \( \mathcal{L}_{g,n}(H) \) which can be interpreted as the holonomy of the link. The definition is however quite complicated and it is difficult to explicitly compute examples. These notions have been redefined in a more conceptual way in [BFK98] (also see [BFK98a]), but in a formalism which is dual to the one used in [BR96] and here (the bridge between the two formalisms is discussed in detail in [Fai19, §5.1.3]). More precisely, in [BFK98], they use a description of the surface as a fat graph and encode operations on this graph by objects called multitangles; then holonomy is defined as a particular multitangle. Computing explicit examples requires to use several rules and is still a bit tricky. Finally, in [BR19, §8], a Wilson loop functor for \( H \)-colored tangles in a thickened punctured disk (i.e. \( g = 0, n \geq 0 \)) is defined as a generalization of the Reshetikhin–Turaev functor in a manner similar to ours. Let us also mention that a holonomy functor is defined in [MW13, §5], but only for paths in a non-thickened ribbon graph.

Let us now describe the content of the paper. We view the surface \( \Sigma^o_{g,n} \) as the fat graph defined by the generators of \( \pi_1(\Sigma^o_{g,n}) \) (see Figures 1 and 2). Our approach is based on a graphical calculus introduced in [3] which transforms complicated computations for tensors with coefficients in \( \mathcal{L}_{g,n}(H) \).
into simple manipulations of diagrams. This graphical calculus is an extension of the graphical calculus in ribbon categories; namely we add a new diagram, called a handle, which corresponds to a matrix with coefficients in $L_{g,n}(H)$. With this tool at hand, the definition of holonomy is almost obvious and it is transparent that it is a generalization of the Reshetikhin–Turaev functor. Moreover, this formulation allows us to define holonomy for tangles (and not just links) in $\Sigma_{g,n} \times [0,1]$; this is especially useful to establish the relation with stated skein algebras.

Section 2 is devoted to preliminaries about surfaces, Hopf algebras, the Reshetikhin–Turaev functor and the algebra $L_{g,n}(H)$. In section 3 we introduce the graphical calculus for tensors with coefficients in $L_{g,n}(H)$, which is our main technical tool in this paper, and we reformulate the defining relations of $L_{g,n}(H)$ in terms of diagram equalities.

In section 4 we define holonomy for tangles in $\Sigma_{g,n} \times [0,1]$ (Definition 4.2). The reason why this operation is called holonomy is explained after Proposition 4.8. We show that holonomy is compatible with the stack product (Theorem 4.4, this result was known for links in the original setting [BR96, Thm. 1], [BFK98b] Thm. 8) and is similar to BR91 Th 8.1 for $g = 0$ and that it behaves well under the action of the mapping class group (Theorem 4.5, with $n = 0$ for simplicity); the proofs are entirely diagrammatic. We then specialize this definition to framed based links and provide a Hennings-type description of the holonomy for such links; this can be compared with the rules given in Hennings setting [Hen98] and with values in $L_{g,n}^{inv}(H)$, namely the subalgebra of invariant elements. Enlarging the set of colors is important when $H$ is non-semisimple because in that case we have symmetric linear forms which are not characters of some $H$-module and hence if we color the links only by $H$-modules (i.e. by characters) we miss a lot of interesting invariant elements.

Let $\Sigma_{g,n}$ be $\Sigma_{g,n}$ with one point removed on its boundary. In section 4 we take $H = U_q(sl_2)$ (quantum group of $sl_2$ at a formal parameter $q^2$) and we show that the stated skein algebra $S_q(\Sigma_{g,n})$ [Le16, CL19] is isomorphic to $L_{g,n}(U_q(sl_2))$ (Theorem 5.3), answering the question of [CL19] about the relation between the two theories. In particular, this gives a presentation by generators and relations of $S_q(\Sigma_{g,n})$ (Corollary 5.5). The isomorphism is defined as follows. For $H = U_q(sl_2)$, all the strands can be colored without loss of generality by the fundamental representation $V_2$, with basis $(v_-, v_+)$. Thanks to the isomorphism $V_2^* \cong V_2$, the holonomy $\text{hol}(T^s)$ of a stated tangle $T^s \in S_q(\Sigma_{g,n})$ does not depend on the orientation of its strands and is an element of $L_{g,n}(U_q(sl_2)) \otimes V_2^\otimes k$, where $k$ is the number of boundary points of $T^s$. Then the isomorphism between $S_q(\Sigma_{g,n})$ and $L_{g,n}(U_q(sl_2))$ is simply given by reading the component of the tensor $\text{hol}(T^s)$ indexed by the state of $T^s$. Our result shows that in the case of the surfaces $\Sigma_{g,n}$, the stated skein algebra is a particular case of the algebra $L_{g,n}(H)$. So it might be possible to generalize stated skein algebras to other Hopf algebras than $U_q(sl_2)$; in particular the states would be vectors in some representations (for $U_q(sl_2)$ the states $-, +$ correspond to the basis vectors $v_-, v_+ \in V_2$).

Finally, in section 5 we explain that the stacking representation of $\Sigma_{0,0} \times [0,1]$ on $\Sigma_{0,0} \times [0,1]$ corresponds through holonomy to the vacuum representation of $L_{g,0}(H)$ on $L_{0,g}(H)$ (Theorem 6.4). As a result, when $H = U_q(sl_2)$, the representation of the (usual) skein algebra $S_q(\Sigma_{0,0})$ obtained via the Wilson loop map and the representation of $L_{g,0}(U_q(sl_2))$ on $L_{0,g}(U_q(sl_2))$ is equivalent to the obvious representation of $S_q(\Sigma_{0,0})$ on $S_q(\Sigma_{0,0+1})$ defined by stacking (Corollary 6.7). When $q$ is a root of unity $\epsilon$, we obtain more interesting (and finite dimensional) representations thanks to the use of the restricted quantum group $\widehat{U}_\epsilon(sl_2)$, as discussed in section 6. If one wants to study explicitly these representations of skein algebras at roots of unity in higher genus (here we only describe explicitly the case of the torus $g = 1$), one problem is to describe $L_{g,0}(\widehat{U}_\epsilon(sl_2))$, for $g > 1$ is complicated both as a vector space and as an algebra. We hope that the generalized Wilson loops defined in this paper may help to understand this space (for instance to find an interesting set of generators or even better a basis in which the multiplication has a suitable form).

Remark 1.1. During the preparation of this manuscript, similar results as in Theorem 5.3 and Theorem 6.4 were proved independently in [GJS19] (see Remark 2.21 and Theorem 6.4 of that paper,
respectively, for the corresponding statements). That work used the framework of factorization homology \[\text{[BZBJ18]}\] and its relationship to skein theory established in \[\text{[Coo18, Coo19]}\], and so our proofs are very different.

Acknowledgments. A significant part of this work was done when I was a PhD student at the University of Montpellier; I thank my past advisors, S. Baseilhac and P. Roche, for their useful remarks.

2 Preliminaries

2.1 Surfaces

We denote by \(\Sigma_{g,n}\) the compact oriented surface of genus \(g\) with \(n\) punctures, except in \(\S 6\) and \(\S 7\) where \(\Sigma_{g,n}\) will be the compact oriented surface of genus \(g\) with \(n\) open disks removed (i.e. we remove open neighborhoods of the punctures). Let \(D \subset \Sigma_{g,n}\) be an open disk disjoint from the punctures, then we denote \(\Sigma_{g,n}^o = \Sigma_{g,n} \setminus D\). We put an orientation on the boundary curve induced by the deletion of \(D\), as indicated in Figures 1 and 2.

![Figure 1: Surface \(\Sigma_{g,n}^o\) and generators of the fundamental group.](image1.png)

![Figure 2: Surfaces \(\Sigma_{2,0}^o\) and \(\Sigma_{0,2}^o\) with canonical fat graphs embedded on them.](image2.png)

The surface \(\Sigma_{g,n}^o\) is represented in Figure 1 under a form suitable for our purposes (for the moment do not consider the black dot on the boundary in the figures); we represent both the situations with
punctures and with open disks removed. This is not the usual view of $\Sigma_{g,n}$. For instance, $\Sigma^o_{2,0}$ and $\Sigma^o_{0,2}$ are represented in a more familiar way in Figure 2. To pass from one view to another, retract $\Sigma^o_{g,n}$ to a neighborhood of the canonical loops generating the fundamental group or conversely embed the fat graph of Figure 1 in the corresponding surface like in Figure 2.

The fundamental group $\pi_1(\Sigma^o_{g,n})$ is a free group generated by the loops $b_1, a_1, \ldots, b_g, a_g, m_{g+1}, \ldots, m_{g+n}$ displayed in Figure 1; moreover, the basepoint of $\pi_1(\Sigma^o_{g,n})$ is represented by a black square dot.

Let $\text{MCG}(\Sigma^o_{g,n})$ be the mapping class group of $\Sigma^o_{g,n}$. For simplicity, we will restrict to $g \geq 1, n = 0$ for the results using or involving the mapping class group. So we recall that $\text{MCG}(\Sigma^o_{g,0})$ is the group of isotopy classes of orientation-preserving diffeomorphisms $\Sigma^o_{g,0} \to \Sigma^o_{g,0}$ which fix the boundary pointwise. A useful feature is that this group is generated by $2g+1$ Dehn twists, called the Humphries generators (see [Kas95, Chap. VIII]). We will often write $\text{MCG}(\Sigma^o_{g,n}) = \text{MCG}(\Sigma^o_{g,0})$.

Finally, we let $\Sigma^o_{g,n}^\bullet$ be the surface $\Sigma^o_{g,n}$ with one point removed from the boundary curve induced by the deletion of the open disc $D$. This is represented by a big black dot in Figures 1 and 2. Note that $\pi_1(\Sigma^o_{g,n}^\bullet) = \pi_1(\Sigma^o_{g,n})$ and $\text{MCG}(\Sigma^o_{g,n}^\bullet) = \text{MCG}(\Sigma^o_{g,n})$.

### 2.2 Hopf algebras, modules, Reshetikhin-Turaev functor

Let $H$ be a braided Hopf algebra with coproduct $\Delta$, counit $\varepsilon$, antipode $S$ and universal $R$-matrix $R$ (see [Kas95 Chap. VIII]). We will often write $R = a_i \otimes b_i$ (with implicit summation on $i$) and we set $R' = b_i \otimes a_i$. The Drinfeld element and its inverse are

$$u = S(b_i)a_i, \quad u^{-1} = S^{-2}(b_i)a_i$$

(1)

It implements $S^2$ by conjugation: $S^2(x) = u x u^{-1}$. In all this paper we assume that $H$ is ribbon, which means that there exists a central and invertible element $v \in H$ such that

$$\Delta(v) = (R'R)^{-1} v \otimes v, \quad S(v) = v, \quad \text{(and thus } \varepsilon(v) = 1, \quad v^2 = uS(u).)$$

It follows that $H$ is pivotal; indeed, the element $g = uv^{-1}$ satisfies

$$\Delta(g) = g \otimes g, \quad \forall x \in H, \ S^2(x) = g x g^{-1}. \quad (2)$$

For any finite dimensional $H$-module $I$, $g$ provides an isomorphism of $H$-modules

$$e_I : I^* \xrightarrow{\sim} I \quad \text{ev}_x \mapsto g^{-1} x$$

(3)

where $\text{ev}_x(\varphi) = \varphi(x)$ for $\varphi \in I^*$ and $x \in I$. If $I$ is a finite dimensional $H$-module, we denote by

$$\underline{I}_T : H \to \text{End}_C(I) \cong \text{Mat}_{\dim(I)}(C)$$

the representation morphism, and by $\underline{h} = \underline{I}_T(h)$ the representation of $h \in H$ on $I$. The coefficients $\underline{h}_{ij} \in H^*$ of $\underline{I}_T$ in some basis are called the matrix coefficients of the $H$-module $I$. The restricted dual of $H$, denoted $H^\circ$, is the vector subspace of $H^*$ generated by all the matrix coefficients of all the finite dimensional $H$-modules. We assume that $H^\circ$ separates the points, which means that if an equality is true in all the finite dimensional representations then it is true in $H$. We denote by $\mathcal{O}(H)$ the vector space $H^\circ$ endowed with the canonical Hopf algebra structure dual to that of $H$.

Let $\text{mod}_l(H)$ be the category of finite dimensional left $H$-modules. The braiding $c_{l,j} : I \otimes J \to J \otimes I$, its inverse $c_{l,j}^{-1} : J \otimes I \to I \otimes J$ and the twist $\theta_I : I \to I$ are defined by

$$c_{l,j}(x \otimes y) = b_i y \otimes a_i x, \quad c_{l,j}^{-1}(y \otimes x) = S(a_i)x \otimes b_i y, \quad \theta_I(x) = v^{-1}x.$$
The $H$-action on the dual $I^*$ is $(h \varphi)(x) = \varphi(S(h)x)$ and the duality morphisms $b_I : \mathbb{C} \to I \otimes I^*$, $d_I : I^* \otimes I \to \mathbb{C}$, $b'_I : \mathbb{C} \to I^* \otimes I$, $d'_I : I \otimes I^* \to \mathbb{C}$ are defined by

$$b_I(1) = v_i \otimes v_i^i, \quad d_I(\varphi \otimes x) = \varphi(x), \quad b'_I(1) = v_i^i \otimes g^{-1} v_i, \quad d'_I(x \otimes \varphi) = \varphi(gx)$$

where $(v_i)$ is a basis of $I$, $(v_i^i)$ is the dual basis and we use Einstein’s convention for pairs of indices (implicit summation).

It is well-known \cite{RT90}, see also \cite{KM01} and \cite{Kas95} XIV.5.1] that there is a tensor functor $F_{RT} : \mathcal{RG}_H \to \text{mod}_I(H)$, where $\mathcal{RG}_H$ is the category of $H$-colored ribbon graphs; $F_{RT}$ is called the Reshetikhin-Turaev functor and takes the following values:

$$F_{RT}(1) = \text{id}_I, \quad F_{RT}(I) = \text{id}_{I^*}, \quad F_{RT}(J) = (f : I \to J),$$

$$F_{RT}(I) = c_{I,J}, \quad F_{RT}(J) = c_{I,J}^{-1}, \quad F_{RT}(I) = \theta_I, \quad F_{RT}(J) = \theta_I^{-1},$$

$$F_{RT}(I) = b_I, \quad F_{RT}(J) = d_I, \quad F_{RT}(I) = b'_I, \quad F_{RT}(J) = d'_I.$$

In the sequel we identify a ribbon graph with its evaluation through $F_{RT}$. Note that we read diagrams from bottom to top.

### 2.3 Algebra $L_{g,n}(H)$ and related notions

Consider $2g + n$ copies of the vector space $H^\circ$ (restricted dual, see above) indexed by the simple closed loops $b_i, a_i, m_j$ which generate $\pi_1(S^1_{g,n})$ (see Figure 1), and denote by $V_{g,n}$ their direct sum:

$$V_{g,n} = H_{b_1}^\circ \oplus H_{a_1}^\circ \oplus \ldots \oplus H_{b_y}^\circ \oplus H_{a_y}^\circ \oplus H_{m_{y+1}}^\circ \oplus \ldots \oplus H_{m_{y+n}}^\circ.$$

Let $i_{b_1}, i_{a_1}, \ldots, i_{b_y}, i_{a_y}, i_{m_{y+1}}, \ldots, i_{m_{y+n}} : H^\circ \to V_{g,n}$ be the canonical injections in each copy. We define

$$\check{B}(1)_j^{i} = i_{b_i}(T_j^{i}), \quad \check{A}(1)_j^{i} = i_{a_i}(T_j^{i}), \quad \ldots, \quad \check{B}(g)_j^{i} = i_{b_i}(T_j^{i}), \quad \check{A}(g)_j^{i} = i_{a_i}(T_j^{i}),$$

$$\check{M}(g + 1)_j^{i} = i_{m_{y+1}}(T_j^{i}), \quad \ldots, \quad \check{M}(g + n)_j^{i} = i_{m_{y+n}}(T_j^{i})$$

for all $I, j, i$. The vector space $V_{g,n}$ is generated by these elements. Now consider the tensor algebra $\mathbb{T}(V_{g,n})$; by definition a generic element in $\mathbb{T}(V_{g,n})$ is a linear combination of formal products of the elements introduced in \cite{4}. We identify the elements of $V_{g,n}$ with their obvious embedding in $\mathbb{T}(V_{g,n})$. Then $\mathbb{T}(V_{g,n})$ is generated as an algebra by the coefficients of the matrices

$$\check{B}(1), \check{A}(1), \ldots, \check{B}(g), \check{A}(g), \check{M}(g + 1), \ldots, \check{M}(g + n) \in \mathbb{T}(V_{g,n}) \otimes \text{End}_C(I)$$

for all the finite dimensional $H$-modules $I$.

**Definition 2.1.** The algebra $L_{g,n}(H)$ is the quotient of $\mathbb{T}(V_{g,n})$ by the relations given by the following matrix equalities:

$$X(i)_{1}^{I}X(i)_{2}^{I}X(i)_{1}^{I}R^{-1}X(i)_{2}^{I}X(i)_{1}^{I} \quad \text{for} \quad 1 \leq i \leq g + n$$

$$R^{I}B(i)_{1}^{I}A(i)_{2}^{I} = A(i)_{1}^{I}R^{I}B(i)_{2}^{I} \quad \text{for} \quad 1 \leq i \leq g$$

$$R^{I}X(i)_{1}^{I}R^{-1}Y(j)_{2}^{I} = Y(j)_{1}^{I}R^{I}X(i)_{1}^{I}R^{-1} \quad \text{for} \quad 1 \leq i < j \leq g + n$$

where $X(i)$ is $A(i)$ or $B(i)$ if $1 \leq i \leq g$ and is $M(i)$ if $g + 1 \leq i \leq g + n$, and the same applies to $Y(j)$.
Let us explain the notations used in this definition. If we have a matrix $\mathcal{U} \in \mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I)$ (resp. $\mathcal{V} \in \mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(J)$) then we denote by $\mathcal{U}_1$ (resp. $\mathcal{V}_2$) its canonical embedding in $\mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I) \otimes \text{End}_\mathbb{C}(J)$. In components, this reads $(\mathcal{U}_1)^{ik}_{jl} = U^{ik}_{j} \delta^k_l$ (resp. $(\mathcal{V}_2)^{ik}_{jl} = \delta^j_i V^k_l$).

If $R \in \text{End}_\mathbb{C}(I) \otimes \text{End}_\mathbb{C}(J)$ is the representation of $R \in H \otimes H$ on $I \otimes J$, and we implicitly identify it with $1 \otimes R \in \mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I) \otimes \text{End}_\mathbb{C}(J)$. Similarly for $R', R^{-1}, R'^{-1}$ (recall that $R'$ is the flip of $R$). Hence these relations are equalities in $\mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I) \otimes \text{End}_\mathbb{C}(J)$. To obtain the defining relations of $\mathcal{L}_{g,n}(H)$, one computes the matrix products in each side of these equalities and identifies the coefficients of the resulting matrices. Note that the defining relations may differ slightly from one paper to another, depending on the conventions chosen by the authors. This algebra first appeared in this form in [Ale94, AGS96, AS96a]; in [AGS95, BR95] to each fat graph $\Gamma$ describing the surface and satisfying certain properties was associated an algebra $\mathcal{L}_\Gamma(H)$.

By construction we have the naturality of the (families of) matrices $\mathcal{X}(i)$, namely for any $H$-morphism $f : I \to J$ it holds

$$ f \mathcal{X}(i) = \mathcal{X}(i) f $$ (8)

where $X(i)$ is $A(i)$ or $B(i)$ if $1 \leq i \leq g$ and is $M(i)$ if $g + 1 \leq i \leq g + n$ (and we identify $f$ with its matrix).

We define a right action $\cdot$ of $H$ on $\mathcal{L}_{g,n}(H)$ by

$$ \mathcal{X}(i) \cdot h = h' \mathcal{X}(i) S(h'') \quad (\text{i.e. } \mathcal{X}(i)^{l}_{m} \cdot h = h'^{l}_{j} \mathcal{X}(i)^{j}_{m} \cdot S(h'')^{m}_{k}) $$ (9)

where we use Sweedler’s notation for the coproduct $\Delta(h) = h' \otimes h''$, Einstein’s convention for pairs of indices and we recall that $\mathcal{X}$ is the representation of $x \in H$ on $I$. Then it is straightforward to check that $\cdot$ endows $\mathcal{L}_{g,n}(H)$ with a structure of (right) $H$-module-algebra. Equivalently, one can work with the associated left $\mathcal{O}(H)$-coaction $\Omega : \mathcal{L}_{g,n}(H) \to \mathcal{O}(H) \otimes \mathcal{L}_{g,n}(H)$:

$$ \Omega(\mathcal{X}(i)) = T \mathcal{X}(i) S(T) \quad (\text{i.e. } \Omega(\mathcal{X}(i)^{l}_{m}) = T^{l}_{j} S(T^{m}_{k}) \otimes \mathcal{X}(i)^{l}_{m}) $$ (10)

where in the right-hand side of the first equality we identify $\mathcal{O}(H)$ (resp. $\mathcal{L}_{g,n}(H)$) with the subalgebra $\mathcal{O}(H) \otimes 1$ (resp. $1 \otimes \mathcal{L}_{g,n}(H)$). The subalgebra of invariant elements is

$$ \mathcal{L}_{g,n}^{\text{inv}}(H) = \{ x \in \mathcal{L}_{g,n}(H) \mid \forall h \in H, \ x \cdot h = \varepsilon(h) x \}. $$ (11)

Equivalently, an element $x$ is invariant if $\Omega(x) = \varepsilon \otimes x$.

Let $x \in \pi_1(\Sigma_{g,n})$ be a simple loop (i.e. without self-crossings). We say that $x$ is positively oriented if its orientation looks as follows (this represents a neighborhood of the basepoint in Figure 1):

(12)

The lift $\mathcal{X} \in \mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I)$ of a positively oriented simple loop $x$ in the representation $I$ is defined as follows: first express $x$ in terms of the generators of $\pi_1(\Sigma_{g,n})$, then replace each generator by the corresponding matrix in the representation $I$: $b_1 \mapsto \mathcal{B}(1), a_1 \mapsto \mathcal{A}(1), \ldots$ and finally multiply the resulting matrix by $v^{N(x)}$, where $v \in H$ is the ribbon element and $N(x) \in \mathbb{Z}$ is defined in [Fai19c, §5.3.2] (the definition of $N(x)$ is not important for the sequel). For instance, $\mathcal{B}_1 = \mathcal{B}(1), \mathcal{A}_1 = \mathcal{A}(1), \ldots$ If $x$ is negatively oriented, then $x^{-1}$ is positively oriented and the lift of $x$ is defined as $\mathcal{X} = (x^{-1})^{-1}$. 7
Note that in general \( \frac{I_j^k}{x} \neq \frac{I_j^k}{xy} \), due to the fact that \( N(xy) \neq N(x) + N(y) \). A remarkable property is that the lifts of a positively-oriented simple loop \( x \) satisfy the fusion relation \([\text{Fai19c, Prop. 5.3.14}]: \)

\[
\frac{I_j^k}{x} = \frac{I_j^k}{x_1} R'_2 x_2 R'^{-1}.
\]

Without the normalization \( \frac{I_{N(x)}}{x} \) this last equality would not be true.

As already said, for results involving the mapping class group we will restrict to \( g \geq 1, n = 0 \) for simplicity (the generalization to any \( g, n \) is possible but would require more discussion). The lift of \( f \in \text{MCG}(\Sigma_{g,0}) \) is an automorphism \( \tilde{f} : \mathcal{L}_{g,0}(H) \to \mathcal{L}_{g,0}(H) \) defined on generators by

\[
\tilde{f}(\frac{I}{B(i)}) = \frac{I}{f(b_i)}, \quad \tilde{f}(\frac{I}{A(i)}) = \frac{I}{f(a_i)}
\]

which obviously means \( \tilde{f}(\frac{I}{B(i)})^k = (\frac{I}{f(b_i)})^k, \tilde{f}(\frac{I}{A(i)})^k = (\frac{I}{f(a_i)})^k \). It holds \( \tilde{f} \circ g = \tilde{f} \circ \tilde{g} \). Moreover, for any simple loop \( x \in \pi_1(\Sigma_{g,0}) \):

\[
\tilde{f}(\frac{I}{x}) = \frac{I}{f(x)}.
\]  

Recall that in \([\text{Fai19b}]) we assumed \( H \) to be finite dimensional and factorizable in order to obtain a projective representation of \( \text{MCG}(\Sigma_{g,0}) \) on some subspace \( \text{Inv}(H^*)\otimes\text{Inv}(H^*) \). Without these assumptions, this representation is a \textit{a priori} not defined. Nevertheless the lift of a mapping class can be defined without these assumptions on \( H \), as we just did above.

### 3 Diagrammatic description of \( \mathcal{L}_{g,n}(H) \)

We will define a graphical calculus for the algebras \( \mathcal{L}_{g,n}(H) \). The basic observation is that these algebras are defined in a matrix way, and that we have matrices labelled by finite dimensional \( H \)-modules. Hence we will extend the usual evaluation of \( H \)-colored ribbon graphs in the sense of \([\text{RT90}]) by adding a diagram corresponding to such matrices.

We denote by \( \frac{I}{X} \) an element of \( \mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I) \) (in other words a matrix with coefficients in \( \mathcal{L}_{g,n}(H) \) of size \( \text{dim}(I) \)), where \( I \) is a finite dimensional \( H \)-module. A typical example is a product of the matrices of generators \( \frac{I}{A(i)}, \frac{I}{B(j)}, \frac{I}{M(k)} \), namely:

\[
\frac{I}{X} = \frac{I}{A(i_1)_{i_1}^l B(j_1)^{m_1} M(k_1)^{n_1}} \cdots \frac{I}{A(i_s)_{i_s}^l B(j_s)^{m_s} M(k_s)^{n_s}}
\]  

with \( l_a, m_a, n_a \in \mathbb{Z} \) and \( 1 \leq i_a, j_a \leq g, g + 1 \leq k_a \leq g + n \); for instance \( \frac{I}{X} = \frac{I}{M(3)^{-2} B(1)^{-1}} \) (it is not obvious that the matrices \( \frac{I}{A(i)}, \frac{I}{B(j)}, \frac{I}{M(k)} \) are invertible; a simple proof is given in Proposition \([\text{3.3 below}]) below). In particular a matrix of the form \( [15] \) is defined for any \( I \) and by \([\text{8}]) it satisfies naturality:

\[
\frac{I}{f X} = \frac{I}{X f}
\]

Note that the lift \( \frac{I}{x} \) of a simple loop \( x \in \pi_1(\Sigma_{g,n}) \) is of the form \( [15] \) except that there is the normalization \( \frac{I_{N(x)}}{x} \), but since \( v \) is central the lifts also satisfies naturality.

Let \( (v_i) \) be a basis of \( I \) and \( (v^j) \) be the dual basis. Then we have an isomorphism of vector spaces

\[
\mathcal{L}_{g,n}(H) \otimes \text{End}_\mathbb{C}(I) \xrightarrow{\sim} \mathcal{L}_{g,n}(H) \otimes I \otimes I^*
\]

\[
\frac{I}{X} \mapsto \frac{I}{X^j_i} \otimes v_i \otimes v^j
\]  

\( \text{Eq. } 17 \)
where we use Einstein’s convention for pairs of indices. In this paper, we systematically identify a matrix $X$ with $X^j_i \otimes v_i \otimes v^j$. Such an element will be represented by the following diagram.

\[
\begin{array}{c}
\text{(18)} \\
\end{array}
\]

The module $I$ colors the strand while the matrix $X$ colors the handle. We define a graphical element corresponding to the other possible orientation of the strand:

\[
\begin{array}{c}
\text{(19)} \\
\end{array}
\]

where $e_I : I^{**} \rightarrow I$ is the isomorphism \([3]\). Let us explain this. To define the graphical element on the left, we put a ribbon graph atop the one defined in \((18)\). This ribbon graph represents a morphism $I^* \otimes I^{**} \rightarrow I^* \otimes I$ in $\text{mod}_I(H)$, which can be applied to $X^j_i \otimes v^i \otimes \langle ?, v_j \rangle$ and gives the element in $\mathcal{L}_{g,n}(H) \otimes I^* \otimes I$ written at the right. The converse to \((19)\) is

\[
\begin{array}{c}
\text{(20)} \\
\end{array}
\]

Note that the two previous diagrammatic identities are completely parallel to the relation between the values assigned by the Reshetikhin-Turaev functor to cups with different orientations.

The Kronecker product of two matrices $X, Y$, defined by

\[
X \otimes Y = X^j_i Y^k_k \otimes v_i \otimes v^j \otimes w_k \otimes w^l
\]

(where $(v_i)$ is a basis of $I$, $(w_k)$ is a basis of $J$ and $(v^j), (w^l)$ are their respective dual bases), is represented by the gluing of the corresponding graphical elements:

\[
\begin{array}{c}
\text{(21)} \\
\end{array}
\]

**Definition 3.1.** A general diagram is obtained by gluing (as in \((21)\)) several copies of the handle diagrams introduced in \((18)\) and \((19)\), and by putting atop an oriented and colored compatible ribbon graph $G$. The evaluation of diagrams is a map $\tilde{F}_{\text{RT}}$ which consists of applying $\text{id}_{\mathcal{L}_{g,n}(H)} \otimes F_{\text{RT}}(G)$ to the tensors associated to the handle diagrams introduced previously, where $F_{\text{RT}}$ is the Reshetikhin-Turaev functor. The evaluation of a diagram is an element of $\mathcal{L}_{g,n}(H) \otimes J_1 \otimes \ldots \otimes J_l$, where $J_1, \ldots, J_l$ are $H$-modules. This is depicted as follows:
\[
\tilde{F}_{\text{RT}} \left( \begin{array}{c}
I_1 \\
X_1 \\
I_k \\
X_k
\end{array} \right) = (\text{id}_{\mathcal{L}_{g,n}(H)} \otimes F_{\text{RT}}(G)) \circ \tilde{F}_{\text{RT}} \left( \begin{array}{c}
I_1 \\
I_1 \\
X_1 \\
X_k
\end{array} \right)
\]

where the double arrows mean that the strands can carry any orientation.

In the sequel, we always identify a diagram with its evaluation through \( \tilde{F}_{\text{RT}} \).

For instance
\[
\begin{array}{c}
I \\
X \\
Y
\end{array} = \begin{array}{c}
I \\
X \\
Y
\end{array} \bigotimes \begin{array}{c}
I \\
X \\
Y
\end{array} \bigotimes \begin{array}{c}
I \\
X \\
Y
\end{array} = \begin{array}{c}
I \\
X \\
Y
\end{array} \bigotimes \begin{array}{c}
I \\
X \\
Y
\end{array} \bigotimes \begin{array}{c}
I \\
X \\
Y
\end{array} \bigotimes \begin{array}{c}
I \\
X \\
Y
\end{array}
\]

and we see that this diagram represents the matrix product \( XY \). Similarly
\[
\begin{array}{c}
I \\
X
\end{array} = \begin{array}{c}
I \\
X
\end{array} \bigotimes \begin{array}{c}
I \\
X
\end{array} \bigotimes \begin{array}{c}
I \\
X
\end{array} \bigotimes \begin{array}{c}
I \\
X
\end{array} = \begin{array}{c}
I \\
X
\end{array} \bigotimes \begin{array}{c}
I \\
X
\end{array} \bigotimes \begin{array}{c}
I \\
X
\end{array} = \text{tr}(\begin{array}{c}
I \\
X
\end{array})
\]

represents the quantum trace of \( \begin{array}{c}
I \\
X
\end{array} \).

**Proposition 3.2.** 1. The defining relations (5), (6), (7) of \( \mathcal{L}_{g,n}(H) \) are respectively equivalent to the diagrammatic relations (23), (24), (25) below.
We recall that $X(i)$ is $A(i)$ or $B(i)$ if $1 \leq i \leq g$ and is $M(i)$ if $g + 1 \leq i \leq g + n$, and the same applies to $Y(j)$.

2. The naturality relation $\text{(16)}$ is equivalent to each one of the following diagrammatic relations:

$$
\begin{array}{ccc}
\begin{tikzpicture}
\node (A) at (0,0) {}; \node (B) at (1,0) {}; \node (C) at (0,-1) {}; \node (D) at (1,-1) {};
\draw (A) -- (B); \draw (C) -- (D);
\end{tikzpicture}
\end{array}
= \begin{array}{ccc}
\begin{tikzpicture}
\node (A) at (0,0) {}; \node (B) at (1,0) {}; \node (C) at (0,-1) {}; \node (D) at (1,-1) {};
\draw (A) -- (B); \draw (C) -- (D);
\end{tikzpicture}
\end{array}
, \\
\begin{array}{ccc}
\begin{tikzpicture}
\node (A) at (0,0) {}; \node (B) at (1,0) {}; \node (C) at (0,-1) {}; \node (D) at (1,-1) {};
\draw (A) -- (B); \draw (C) -- (D);
\end{tikzpicture}
\end{array}
= \begin{array}{ccc}
\begin{tikzpicture}
\node (A) at (0,0) {}; \node (B) at (1,0) {}; \node (C) at (0,-1) {}; \node (D) at (1,-1) {};
\draw (A) -- (B); \draw (C) -- (D);
\end{tikzpicture}
\end{array}
\end{array}

(26)

where $X$ is any matrix of the form $\text{(15)}$.

Proof. 1. First note that for any $a, b \in H$, it holds

$$
(\hat{X}(i)b^T_k \otimes v_j \otimes v^k = X(i)^T_k \otimes av_j \otimes S^{-1}(b)v^k. \tag{27}
$$

To show $\text{(23)}$, write $R = a \otimes b$ (with implicit summation on $\alpha$), so that $\text{(5)}$ becomes

$$
\hat{X}(i) = \left( X(i)^T b^T \right)_{\alpha} \left( a \otimes X\left( S(a) \right) \right)_{\beta}. \tag{5}
$$

Hence, by $\text{(27)}$ and the definition of the braiding in $\text{mod}_I(H)$ we have

$$
\hat{X}(i)^T \otimes v_k \otimes w_m \otimes w^n \otimes v^l
= \left( \hat{X}(i) \right)^T b^T \left( a \otimes X\left( S(a) \right) \right)_{\alpha} \otimes v_k \otimes w_m \otimes w^n \otimes v^l
= X(i)^T \hat{X}(i)^T \otimes v_k \otimes a \otimes w_m \otimes a \otimes w^n \otimes S^{-1}(b)v^l
= X(i)^T \hat{X}(i)^T \otimes v_k \otimes S(a)w_m \otimes S(a)w^n \otimes S(b)v^l
= X(i)^T \hat{X}(i)^T \otimes (id_I \otimes id_J \otimes c^{-1}_{J,a}) \otimes (id_I \otimes c^{-1}_{J,a} \otimes id_J) \otimes (v_k \otimes v^l \otimes w_m \otimes w^n).$$

This corresponds to the desired diagrammatic relation. To show $\text{(24)}$ we first have to rewrite $\text{(6)}$:

$$
\hat{R}B(i)_1 \hat{R}A(i)_2 \hat{R}B(i)_1 = A(i)_2 \hat{R}B(i)_1 = A(i)_2 (a \otimes b)_{\alpha} \hat{R}B(i)_1 = (a \otimes b)_{\alpha} A(i)_2 \hat{R}B(i)_1.
$$

Using the properties of the antipode $S$ and of $R$ (see $\text{[Kas95]}$), we see that $a \otimes b \otimes S(b) = 1 \otimes 1$; hence we get

$$
\hat{A}(i)_2 \hat{B}(i)_1 = (a \otimes b)_{\alpha} \hat{R}A(i)_2 \hat{R}B(i)_1 S(b) = \left( a \otimes b \otimes \hat{B}(i)_1 \right) \left( b \otimes a \otimes \hat{A}(i)_2 \right) S(b)_{\alpha}.$$

11
By (27), the fact that \((S \otimes S)(R) = R\) and the definition of the braiding in \(\text{mod}_I(H)\) we get

\[
\begin{aligned}
\frac{J}{I} A(i)_I^m B(i)_n^m & \otimes w_k \otimes w^l \otimes v_m \otimes v^n \\
& = \left( \frac{J}{I} a_\alpha B(i)_I^m B(i)_n^m \delta^j_k \right)^m_a \left( b_\beta A(i)_I^m b_\delta \right)_j^I (S(b_\alpha))_j^I A(i)_I^m B(i)_n^m \\
& = B(i)_n^m A(i)_I^m \otimes b_\beta a_\gamma w_k \otimes S^{-1}(b_\delta S(b_\alpha))_j^I a_\alpha a_\beta v_m \otimes S^{-1}(b_\gamma a_\delta)_j^I v_n \\
& = B(i)_n^m A(i)_I^m \otimes b_\beta S(a_\gamma) w_k \otimes b_\alpha b_\beta w^l \otimes a_\alpha a_\beta v_m \otimes a_\delta b_\gamma v^n \\
& = B(i)_n^m A(i)_I^m \otimes (\text{id}_I \otimes c_{J,J^*} \otimes \text{id}_{J^*}) (b_\beta S(a_\gamma) w_k \otimes a_\beta v_m \otimes b_\delta w^l \otimes a_\delta b_\gamma v^n) \\
& = B(i)_n^m A(i)_I^m \otimes (\text{id}_I \otimes c_{J,J^*} \otimes \text{id}_{J^*}) \circ (c_{J,J^*} \otimes c_{J,J^*}) (v_m \otimes S(a_\gamma) w_k \otimes b_\gamma v^n \otimes w^l) \\
& = B(i)_n^m A(i)_I^m \otimes (\text{id}_I \otimes c_{J,J^*} \otimes \text{id}_{J^*}) \circ (\text{id}_I \otimes c_{J,J^*} \otimes \text{id}_{J^*}) (v_m \otimes v^n \otimes w_k \otimes w^l)
\end{aligned}
\]

which corresponds to the desired diagrammatic relation. (25) is proven in a similar way.

2. By (16), we have

\[
\begin{aligned}
\frac{J}{I} X_i^k \otimes (f \otimes \text{id}_{J^*})(v_i \otimes v^j) & = \frac{J}{I} X_i^k \otimes f^k_i v_k \otimes v^j = (f X)_j^I \otimes v_k \otimes v^j = (X f)_j^I \otimes w_k \otimes w^j \\
& = \frac{J}{I} X_i^k \otimes w_k \otimes f^j_i v^j = \frac{J}{I} \otimes (\text{id}_I \otimes f^*))(w_k \otimes w^j)
\end{aligned}
\]

where \(f^* : J^* \rightarrow I^*\) is the transpose of \(f\). This gives the first diagram below. The second diagram is equivalent to the first thanks to (19) and the equality \(f \circ e_I = e_J \circ f^*\).

This diagrammatic reformulation of the defining relations of \(\mathcal{L}_{g,m}(H)\) easily implies two basic well-known properties of the matrices \(B(i), A(i), M(i)\):

**Proposition 3.3.** Let \(X(i)\) be \(A(i)\) or \(B(i)\) if \(1 \leq i \leq g\) and be \(M(i)\) if \(g + 1 \leq i \leq g + n\).

1. The reflection equation \(R_{12} X(i)_1(R^i)_{12} X(i)_2 = X(i)_2 R_{12} X(i)_1(R^i)_{12}\) holds and is equivalent to the following diagrammatic equality:

\[
\begin{aligned}
\includegraphics[width=0.8\textwidth]{diagram1.png}
\end{aligned}
\]

2. The matrix \(\frac{J}{I} X(i)\) is invertible with inverse \(\frac{J}{I} X(i)^{-1} = \frac{J}{I} u^{-1} S(b_i)^I X(i) d_i\) where \(u\) is the Drinfeld element (11), \(^t\) is the transpose and \(R = a_i \otimes b_i\). Diagrammatically:

\[
\begin{aligned}
\includegraphics[width=0.8\textwidth]{diagram2.png}
\end{aligned}
\]

**Proof.** 1. This is a consequence of (26) and (23):
It is left to the reader to check that the diagrammatic equality is equivalent to the matrix equality.  
2.  This is also a consequence of (26) and (23):  

\[ \mathbb{I}_{\dim(I)} = I^\ast \mathbb{C}_X(i) I \otimes I \]  

Again it is left to the reader to check using (19) that the diagrammatic and matrix equalities are equivalent.  

\[ \mathbb{I}_{\dim(I)} = I^\ast \mathbb{C}_X(i) I \otimes I \]

Remark 3.4. The proof of the previous proposition uses only the naturality and the fusion relation \[ (5) \], hence the result applies to any family of matrices \( (X)_{I \in \text{mod}(H)} \) satisfying these properties and in particular to the lifts \( (\tilde{X})_{I \in \text{mod}(H)} \) of a positively-oriented simple loop \( x \in \pi_1(\Sigma^o_{g,n}) \) (see section 2.3).

4 Holonomy and Wilson loops

4.1 General definition for tangles

Recall that the surface \( \Sigma^o_{g,n} \) is defined in §2.1; it is a punctured bordered surface in the sense of [Le16, §2], [CL19, §2.2].

Let \( \Sigma = \Sigma^o_{g,n} \times [0,1] \) be the thickening of \( \Sigma^o_{g,n} \). For a point \( p = (x,t) \in \Sigma \) we call \( t \in [0,1] \) the height of \( p \). The following definition is taken from [Le16, §2.2], except that we add an orientation and a coloring on the tangles. Note however that we restrict to the surfaces \( \Sigma^o_{g,n} \) (we do not consider more general punctured bordered surfaces).

Definition 4.1. 1. A \( H \)-colored \( \partial \Sigma \)-tangle is an oriented, framed, compact, properly embedded 1-dimensional submanifold \( T \subset \Sigma \) such that
• at every point of $\partial T = T \cap \partial \Sigma$ the framing is vertical
• the points of $\partial T$ have distinct heights
• each connected component of $T$ is colored (i.e. labelled) by a finite dimensional $H$-module.

We denote by $\mathcal{T}(\Sigma_{g,n})$ the set of isotopy classes of such tangles.

2. An isotopy of $H$-colored $\partial \Sigma$-tangles is an isotopy preserving these defining properties.

3. A $H$-colored $\partial \Sigma$-tangle diagram is the projection of $T \subset \Sigma_{g,n} \times [0,1]$ on $\Sigma_{g,n}$, together with the colors, the over/underpassing information at each double point and the height information at each boundary point. We assume as usual that $T$ is in general position before doing the projection.

4. Let $\mathcal{O}$ be an orientation of the boundary curve $\partial \Sigma_{g,n}$. A $\partial \Sigma$-tangle diagram is $\mathcal{O}$-ordered if the heights of the boundary points are increasing when one goes along $\partial \Sigma_{g,n}$ according to $\mathcal{O}$.

Up to isotopy, a $\partial \Sigma$-tangle $T$ can always be presented by a $\mathcal{O}$-ordered diagram. More precisely, up to isotopy, a $H$-colored $\partial \Sigma$-tangle diagram can always be presented as follows:

where the handles contain only bunches of parallel strands, $T$ is a (non-unique) tangle, the $H$-modules $I_i, J_i, K_i, V_i$ color the strands, the double arrows mean that each strand is oriented, the boundary points are all on the line at the top of the rectangle and the big dot ($\bullet$) is the point that we have removed from $\partial \Sigma_{g,n}$. Last but not least, the boundary points of $T$ have increasing heights with respect to the orientation of the boundary represented by the arrow. Note that $k$ may be equal to 0, which means that $T$ is a link (no boundary points).

**Definition 4.2.** Let $T \in \mathcal{T}(\Sigma_{g,n})$ be represented by a $H$-colored $\partial \Sigma$-tangle diagram as in (30). The holonomy of $T$ is an element $\text{hol}(T) \in \mathcal{L}_{g,n}(H) \otimes V_1^{a_1} \otimes \ldots \otimes V_k^{a_k}$ defined as the evaluation (see Definition 3.1) of the following diagram:

The symbol $a_i \in \{\downarrow, \uparrow\}$ depends on the orientation of the strands ($a_i = \downarrow$ if the strand is oriented downwards and $a_i = \uparrow$ else) and we define $V_i^\downarrow = V_i$ and $V_i^\uparrow = V_i^*$. If $T$ does not have boundary points then $\text{hol}(T)$ is just an element of $\mathcal{L}_{g,n}(H)$.

We note that $\text{hol}(T)$ does not depend on the choice of the tangle $T$. Indeed, since the Reshetikhin-Turaev functor is an isotopy invariant, the evaluation of the diagram in Definition 3.1 depends only on the isotopy class of $T$. Moreover, if we drag certain crossings, cups and caps along the handles in order to obtain another tangle $T'$ representing $T$, then this does not change the value of $\text{hol}(T)$ thanks to naturality (26):
Let \( T^* \) be the opposite to the one of [Le16, CL19]: here \( T^1 \) means that we put \( T_1 \) below \( T_2 \) in the thickened surface.

For \( x \otimes v \in \mathcal{L}_{g,n}(H) \otimes V_1 \otimes \ldots \otimes V_k \) and \( y \otimes w \in \mathcal{L}_{g,n}(H) \otimes W_1 \otimes \ldots \otimes W_1 \) (with \( x, y \in \mathcal{L}_{g,n}(H) \), \( v \in V_1 \otimes \ldots \otimes V_k \) and \( w \in W_1 \otimes \ldots \otimes W_1 \), we define

\[
(x \otimes v) \otimes (y \otimes w) = xy \otimes v \otimes w \in \mathcal{L}_{g,n}(H) \otimes V_1 \otimes \ldots \otimes V_k \otimes W_1 \otimes \ldots \otimes W_1.
\]

**Theorem 4.4.** Let \( T_1, T_2 \in \mathcal{F}(\Sigma_{g,n}^\circ) \). It holds

\[
\text{hol}(T_1 \ast T_2) = \text{hol}(T_1) \circ \text{hol}(T_2).
\]

**Proof.** See the appendix at the end of the paper (page 43).

The holonomy behaves well under the action of the mapping class group. As said in §2.3, we will prove this for \( n = 0 \). Note that \( \text{MCG}(\Sigma_{g,0}) \) acts on \( \Sigma_{g,0}^\circ \times [0,1] \) by \( f(x,t) = (f(x),t) \) and recall the lift \( \tilde{f} \) of a mapping class \( f \) defined in (13).

**Theorem 4.5.** Let \( f \in \text{MCG}(\Sigma_{g,0}) \) and let \( T \in \mathcal{F}(\Sigma_{g,0}^\circ) \), then

\[
\text{hol}(f(T)) = \tilde{f} \otimes \text{id}_{V_1^{a_1} \otimes \ldots \otimes V_k^{a_k}}(\text{hol}(T))
\]

where the \( V_i^{a_i} \) are the colors of the boundary strands of \( T \) (see Definition 4.2).

**Proof.** The proof is purely diagrammatic. We can assume that \( f \) is one of the Humphries generators \( \tau_\gamma \) [FM12, §4.4.3] where \( \gamma \) is one of the simple closed curves depicted in [FM12, Fig. 4.5]. Let \( U \subset \Sigma_{1,0}^\circ \) be a connected subset containing all the handles and a very small part of the bottom of the rectangle (see Figure 4). By isotopy, we can assume that \( \gamma \subset U \). Also by isotopy we can assume that \( T \cap (U \times [0,1]) \) contains only bunches of parallel strands and then by another isotopy that \( T \cap (U \times [0,1]) \subset U \times \{0\} \). Then \( \tau_\gamma(T) \) is obtained by computing \( \tau_\gamma(T \cap (U \times \{0\})) \) in the usual way in the surface \( \Sigma_{g,0}^\circ \times \{0\} \). Moreover, as in the proof of Theorem 4.4 we can assume up to introducing
coupons that each handle contains only one positively oriented strand (as in (18)). Now, if \( f = \tau_{a_1} \), which is one of the Humphries generators (\( a_1 \) is \( m_1 \) in the notations of [FM12, Fig. 4.5]), we can restrict to \( \Sigma^\circ \bullet \) (since \( a_1 \) is contained in this subsurface) and then we have the graphical computation in \( L_{1,0}(H) \) represented in Figure 3. We used the fusion relation, the inverse of the reflection equation (28) and the definition of the lift \( \tilde{\tau}_a = \tilde{\tau}_{a_1} \) (see section 2.3): \[
\tilde{\tau}_a(A) = A, \quad \tilde{\tau}_a(B) = v^{-1}BA.
\]
The equalities for the others Humphries generators are shown similarly, although the diagrams are more cumbersome.

For further use let us describe the behaviour of hol when we change the orientation of a strand. Consider (not colored) \( \partial \Sigma \)-tangles \( T^+, T^- \) with one connected component, which are equal as un-oriented tangles and which are oriented as follows:

\[
T^+ = \quad \bullet \quad \ldots \quad \bullet \\
\quad \ldots \quad \ldots \quad \ldots
\]
\[
T^- = \quad \bullet \quad \ldots \quad \bullet \\
\quad \ldots \quad \ldots \quad \ldots
\]

For \( I \) a finite dimensional \( H \)-module, we denote by \( \text{hol}^I(T^\pm) \) the value of hol on the \( \partial \Sigma \)-tangle \( T^\pm \) colored by \( I \). Then thanks to (19), (20), (26), it is easy to see that

\[
\text{hol}^I(T^-) = (\text{id}_I \otimes e_I)(\text{hol}^I(T^+))
\]
\[
\text{hol}^I(T^+) = (e_I \otimes \text{id}_I)(\text{hol}^I(T^-)).
\]

This is obviously generalized to arbitrary \( \partial \Sigma \)-tangles.

### 4.2 Holonomy of a link

We will now specialize Definition 4.2 to the case of \( H \)-colored framed links in \( \Sigma^\circ_{g,n} \times [0,1] \) with basepoints, so that it will become more clear why we call this operation the “holonomy”.

**Definition 4.6.** A based \( H \)-colored link \( L \subset \Sigma = \Sigma^\circ_{g,n} \times [0,1] \) is an oriented and framed embedding of circles such that:

- for each connected component \( L_i \) of \( L \), we have \( L_i \cap \partial \Sigma = \{ p_i \} \); \( p_i \) is called a basepoint
- the basepoints have distinct heights
- each connected component of \( L \) is colored (i.e. labelled) by a finite dimensional \( H \)-module

An isotopy of based \( H \)-colored links is an isotopy compatible with the defining properties and preserving globally the boundary \( \partial \Sigma \) (so that basepoints can be moved along the boundary but cannot be suppressed). It is clear that using isotopy any based \( H \)-colored link can be presented as follows, where the basepoints \( p_1, \ldots, p_k \) have strictly increasing heights:
Figure 3: Proof of the equality $\text{hol} \circ \tau_a(T) = (\tilde{\tau}_a \otimes \text{id}) \circ \text{hol}(T)$. 
We will always use this presentation in the sequel.

To a based $H$-colored link $L$ we associate a $H$-colored $\partial \Sigma$-tangle $T(L)$ as follows. First using isotopy, represent $L$ as in (32). Then at each basepoint $p_i$ apply one of the following substitutions, depending on the orientation of the connected component $L_i$ attached to that basepoint:

where the resulting boundary points are arranged so that $p_1^-, p_1^+, \ldots, p_k^-, p_k^+$ (in this order) have strictly increasing heights (to demistify the reason of the right hand-side assignment, look at (29) as well as at the proof of Proposition 4.8 and at Remark 4.14 below). Using this transformation, we define the holonomy of a $H$-colored based link as

$$ \text{hol}(L) = \text{hol}(T(L)). $$

By definition, we have

$$ \text{hol}(L) \in \mathcal{L}_{g,n}(H) \otimes V_1 \otimes V_1^* \otimes \ldots \otimes V_k \otimes V_k^* = \mathcal{L}_{g,n}(H) \otimes \text{End}_C(V_1) \otimes \ldots \otimes \text{End}_C(V_k). $$

Hence $\text{hol}(L)$ can be written as $x \otimes N_1 \otimes \ldots \otimes N_k$ ($N_i \in \text{End}_C(V_i)$), with implicit summation to simplify notations.

**Proposition 4.7.** The right action $[0]$ of $h \in H$ on the coefficients of the tensor $\text{hol}(L)$ is given by

$$ \text{hol}(L) \cdot h = x \otimes h(1)^1 N_1 S(h(2)) \otimes \ldots \otimes h(2k-1)^1 N_k S(h(2k)) $$

where $\Delta^{(2k-1)}(h) = h(1) \otimes \ldots \otimes h(2k)$ is the coproduct iterated $2k - 1$ times.

**Proof.** This is straightforward. For instance, consider the following link $L \subset \Sigma_{1,0}^*$ with two basepoints:

![Diagram](image)

Then using the identification (17) together with (9), (27) and the fact that $F_{\text{RT}}(T_{\text{tot}}) : I \otimes I^* \otimes J \otimes J^* \to V_1 \otimes V_1^* \otimes V_2 \otimes V_2^*$ is $H$-linear, we obtain

$$ \text{hol}(L) \cdot h = \left( B^j_j A^k_k \right) \cdot h \otimes F_{\text{RT}}(T_{\text{tot}})(x_i \otimes x^j \otimes y_k \otimes y^l) $$

$$ = \left( h(1)^1 B S(h(2))^i \right) \left( h(3)^1 A S(h(4))^k \right) \otimes F_{\text{RT}}(T_{\text{tot}})(x_i \otimes x^j \otimes y_k \otimes y^l) $$

$$ = B^j_j A^k_k \otimes F_{\text{RT}}(T_{\text{tot}}) \left( h(1)^1 \otimes h(2)^i \otimes h(3)^k \otimes h(4)^l \right) $$

$$ = h(1)^1 N_1 m \otimes h(2)^i v_m \otimes h(3)^k v_n \otimes h(4)^l w_o \otimes h(4)^p $$

$$ = x \left( h(1)^1 N_1 S(h(2))^m \right) \left( h(3)^1 N_2 S(h(4))^i \right) \otimes v_m \otimes v_n \otimes w_o \otimes w^p $$

Therefore, we have

$$ \text{hol}(L) \cdot h = x \otimes h(1)^1 N_1 S(h(2)) \otimes \ldots \otimes h(2k-1)^1 N_k S(h(2k)) $$

where $(x_i), (y_i), (v_i), (w_i)$ are basis of $I, J, V_1, V_2$ respectively. 

$\square$
A simple loop \( x \in \pi_1(\Sigma_{g,n}) \) can naturally be viewed as a based link \( x \subset \Sigma_{g,n} \times \{0\} \). For the next result we will use the mapping class group, so we restrict to \( n = 0 \) for simplicity. We denote by \( \text{hol}^I(x) \) the value of \( \text{hol} \) on the simple loop \( x \) colored by \( I \). Thanks to Theorem \ref{thm:holonomy} we have for all \( f \in \text{MCG}(\Sigma_{g,0}) \)

\[
\tilde{f}(\text{hol}(x)) = \text{hol}(f(x))
\]

where the matrix at the left-hand side is obviously defined by \( \tilde{f}(\text{hol}(x)) \cdot_j = \tilde{f}(\text{hol}(x)) \cdot_j \). Also recall the lift of a simple loop defined in \ref{sec:lifting}.

**Proposition 4.8.** For any simple loop \( x \in \pi_1(\Sigma_{g,0}) \) and finite dimensional \( H \)-module \( I \) it holds

\[
\text{hol}^I(x) = \frac{I}{x}.
\]

**Proof.** Observe first that if the result is true for some simple loop \( x \), then it is true for every \( f(x) \), where \( f \in \text{MCG}(\Sigma_{g,0}) \). Indeed, thanks to \ref{eq:holonomy} and \ref{eq:lift}

\[
\text{hol}^I(f(x)) = \tilde{f}(\text{hol}^I(x)) = \tilde{f}(\frac{I}{x}) = \frac{I}{f(x)}.
\]

Now, one can check directly that the result is true for the loops

\[
a_1, s_1 = b_1a_1^{-1}b_1^{-1}a_1, s_2 = b_1a_1^{-1}b_1^{-1}a_1b_2^{-1}b_2^{-1}a_2, \ldots, s_g = b_1a_1^{-1}b_1^{-1}a_1 \ldots b_g a_g^{-1}b_g^{-1}a_g.
\]

These are positively oriented simple loops (see \ref{eq:positively_oriented_loops}). \( a_1 \) is a non-separating loop while \( s_1, \ldots, s_g \) are separating loops exhausting all the possible topological types of separating loops (see \cite[§1.3.1]{FM12}). Hence, if \( y \) is a positively oriented simple loop, there exists a homeomorphism \( f \in \text{MCG}(\Sigma_{g,0}) \) such that \( y = f(x) \) where \( x \) is one of the loops in \ref{eq:positively_oriented_loops}. It follows that the result is true for any positively oriented simple loop. The result for negatively oriented simple loops is deduced as follows:

\[
\text{hol}^I(\tau_x) = \begin{cases} I & x \rightarrow I, \\
\text{id}_{I^*} & I \rightarrow I, \\
\text{id}_{I^*} & I \rightarrow I, \\
\end{cases}
\]

where \( T_x \) is the part of \( x \) outside a small neighborhood of the basepoint and \( D_{x^{-1}} \) is the corresponding part of diagram (but with opposite orientation) obtained when applying \( \text{hol}^I \). For the first equality we used the definition of \( \text{hol} \) together with \ref{eq:naturalness}, for the second we applied the previously established result for the positively oriented loop \( x^{-1} \) and also the naturality of braiding and twist, for the third we used \ref{eq:sign_change} and for the fourth we used Remark 3.4. We are done since by definition \( (\frac{I}{x^{-1}})^{-1} = \frac{I}{x} \). □

Recall what is holonomy in the classical case. For a discrete \( G \)-connection \( \nabla \in \mathcal{A}_{g,n} = \text{Hom}(\pi_1(\Sigma_{g,n}), G) \) and a simple loop \( x \in \pi_1(\Sigma_{g,n}) \), the holonomy is simply \( \text{hol}(x)(\nabla) = \nabla(x) \in G \). Now, if \( V \) is a finite dimensional representation of \( G \), we define \( \text{hol}^V(x)(\nabla) \) to be \( \nabla(x) \), namely the representation of \( \nabla(x) \) on \( V \). By taking matrix coefficients, we obtain functions on \( \mathcal{A}_{g,n} \):

\[
\text{hol}^V(x)_j : \mathcal{A}_{g,n} \rightarrow \mathbb{C}, \quad \nabla \mapsto \nabla(x)_j.
\]

Hence \( \text{hol}^V(x) \in \mathbb{C}[\mathcal{A}_{g,n}] \otimes \text{End}_\mathbb{C}(V) \). Let \( \tilde{V}(1) = \text{hol}^V(b_1), \tilde{V}(1) = \text{hol}^V(a_1), \ldots \) Now express \( x \) in terms of the generators of \( \pi_1(\Sigma_{g,n}) \) and replace each generator by the corresponding matrix in the representation \( V \): \( b_1 \mapsto \tilde{V}(1), a_1 \mapsto \tilde{V}(1), \ldots \); this defines the lift \( \tilde{\pi} \in \mathbb{C}[\mathcal{A}_{g,n}] \otimes \text{End}_\mathbb{C}(V) \) of \( x \) in that representation. It is clear that \( \text{hol}^V(x) = \tilde{\pi} \), which is exactly the same formula as in Proposition 4.8 and then justifies the name “holonomy” for Definition 4.2.
4.3 Hennings formulation of the holonomy of a based link

We now give a description à la Hennings [Hen96] of the holonomy which will be useful in the next section. This description applies only to based links.

We will use universal elements. These are elements \( B(i), A(i), M(i) \in \mathcal{L}_{g,n}(H) \otimes H \) such that

\[
\begin{align*}
I^i B(i) &= (\text{id} \otimes \tilde{T})(B(i)), \\
I^i A(i) &= (\text{id} \otimes \tilde{T})(A(i)), \\
I^i M(i) &= (\text{id} \otimes \tilde{T})(M(i))
\end{align*}
\]  

(36)

for all finite dimensional \( H \)-module \( I \) and all \( i \) (we recall that \( \tilde{T} \) is the representation morphism of \( H \) on \( I \)). In the sequel we assume that \( H \) is such that these elements exist; this assumption is fulfilled by relevant classes of Hopf algebras.

**Lemma 4.9.** If \( H \) is finite dimensional or if \( H = U_q(\mathfrak{g}) \) with \( q \) generic, then there exist universal elements satisfying \((36)\).

**Proof.** We can restrict to \( \mathcal{L}_{0,1}(H) \), and we let \( I^i M = I^i M(1) \) for all \( I \). Assume first that \( H \) is finite dimensional; then we can use the regular representation \( H \). Write \( \tilde{M} = x_i \otimes f_i \in \mathcal{L}_{0,1}(H) \otimes \text{End}_C(H) \) and define \( M = x_i \otimes f_i(1) \in \mathcal{L}_{0,1}(H) \otimes H \). Let \( \rho_a \in \text{End}_H(H) \) defined by \( \rho_a(h) = ha \). By \((8)\) it holds \( H \rho_a = \rho_a H \), thus we have for all \( a \in H \):

\[
x_i \otimes f_i(a) = x_i \otimes f_i \circ \rho_a(1) = x_i \otimes \rho_a \circ f_i(1) = x_i \otimes f_i(1)a = x_i \otimes \tilde{T}(f_i(1))(a)
\]

which shows that \( \tilde{M} = (\text{id} \otimes \tilde{T})(M) \). Next consider a direct sum \( H^{\otimes N} \), and let \( j \alpha : H \to H^{\otimes N} \) and \( p \alpha : H^{\otimes N} \to H \) be the associated canonical injections and projections. By \((8)\), we have

\[
H^{\otimes N} M = \sum_{\alpha} j \alpha M p \alpha = \sum_{\alpha} (\text{id} \otimes j \alpha \tilde{T} p \alpha)(M) = (\text{id} \otimes H^{\otimes N} \tilde{T}')(M).
\]

Finally, let \( I \) be any finite dimensional \( H \)-module. Since \( I \) is finitely generated there is a surjective morphism \( \pi : H^{\otimes N} \to I \) for some \( N \) and hence \( \tilde{M} \pi = \pi \tilde{M} = (\text{id} \otimes \pi \tilde{T}')(M) = (\text{id} \otimes I^i \tilde{T}')(M) \).

But since \( \pi \) is surjective, it is right invertible and thus \( \tilde{M} = (\text{id} \otimes \tilde{T}')(M) \).

Now take \( H = U_q(\mathfrak{g}) \). The map \( \Phi : \mathcal{L}_{0,1}(H) \to H \) defined by \( \tilde{M} \to (\text{id}_H \otimes \tilde{T}')(R'R) \) is an injective morphism of algebras (see [BFT99] Th. 4.3 and the references therein). Then under the identification \( \mathcal{L}_{0,1}(H) \cong \text{im}(\Phi) \) we have \( \tilde{M} = (\text{id} \otimes I^i \tilde{T}')(M) \), where \( M = R'R \in \text{im}(\Phi) \otimes H \). Note that \( M \) actually belongs to some completion but we will not discuss this detail here.

We write

\[
B(i) = B(i)_0 \otimes B(i)_1, \quad A(i) = A(i)_0 \otimes A(i)_1, \quad M(i) = M(i)_0 \otimes M(i)_1
\]

with implicit summation to simplify notations. By definition, the right action \((9)\) of \( H \) on \( \mathcal{L}_{g,n}(H) \) satisfies

\[
\mathcal{X}_0 \cdot h \otimes \mathcal{X}_1 = \mathcal{X}_0 \otimes h' \mathcal{X}_1 S(h''
\]

where \( \mathcal{X} \) is \( B(i), A(i) \) or \( M(i) \)

Let \( L \) be a based link presented as in \((32)\) but without coloring. First, for each basepoint \( p_i \) we define a coupon \( \text{Or}_i \) depending on the orientation of the strand and which is the analogue of \((33)\):

\[
... \quad \Rightarrow \quad \text{Or}_i = \quad ...
\]

\[
... \quad \Rightarrow \quad \text{Or}_i = \quad ...
\]
Then we form the following diagram:

\[
\begin{array}{c}
\text{Or}_1 \quad \cdots \quad \text{Or}_k \\
B(i) \quad A(i) \quad M(j) \\
\cdots \\
T
\end{array}
\]

We put the dotted line to stress that the diagram can be deformed by isotopy, but with the restriction that all the points below (resp. above) the line must remain below (resp. above) the line. The evaluation of this diagram is an element \( \text{Hen}(L) \in \mathcal{L}_{g,n}(H) \otimes H^{\otimes k} \) computed according to the following rules, which generalize those defining the Hennings invariant. Starting from one of the basepoints labelled \( 1, \ldots, k \) and following the strand according to its orientation, we multiply together from left to right the values associated to each graphical element that we encounter until we come back to the basepoint:

\[
\begin{array}{c}
\mathcal{X}^{(1)}_1 \\
\mathcal{X}^{(l)}_1 \\
\mathcal{X}
\end{array}
\]

Here \( \mathcal{X} = \mathcal{X}_0 \otimes \mathcal{X}_1 \) is one of the \( B(i), A(i), M(i) \) and \( \Delta^{(m)}(\mathcal{X}_1) = \mathcal{X}_1^{(1)} \otimes \cdots \otimes \mathcal{X}_1^{(m+1)} \) is the iterated coproduct. Note that the handle contains a bunch of parallel strands and the picture represents the value associated to the \( l \)-th strand. Then by applying this rule for each starting point, we obtain elements \( Z_1, \ldots, Z_k \in H \), and we define

\[
\text{Hen}(L) = (B(1)_0 A(1)_0 \cdots B(g)_0 A(g)_0 M(g + 1)_0 \cdots M(g + n)_0) \otimes Z_1 \otimes \cdots \otimes Z_k.
\]

Here is an example in \( \Sigma_{0,1} \times [0,1] \):

\[
\begin{array}{c}
\mathcal{M} \\
\mathcal{M}
\end{array}
\]

where we used that \( b_i g a_i = v^{-1} \).

The evaluation of \( \text{Hen}(L) \) on representations almost gives back the holonomy:

\[
(id \otimes T \otimes \cdots \otimes T)(\text{Hen}(L)) = (V_1^g \otimes \cdots \otimes V_k^g) \text{hol}^{V_1 \cdots V_k}(L)
\]
4.4 Generalized Wilson loops

In the classical case, a Wilson loop around a simple curve $\gamma$ assigns to a connection the trace of the holonomy of $\gamma$ in some representation; this quantity is gauge invariant. We will straightforwardly generalize this to the quantized case, by replacing the simple curve by a based link and by replacing the trace by a quantum trace (or more generally by a symmetric linear form shifted by $g$).

Let $L$ be an uncolored based link with $k$ connected components. Let $f \in (H^\circ)^{\otimes k}$ (recall that $H^\circ$ is the restricted dual of $H$). By definition $f$ is a linear combination of the form

$$f = \sum_{i_1, \ldots, i_k} (\Lambda_{i_1 \ldots i_k})^{i_1 \ldots i_k} T_{j_1}^{i_1} \otimes \ldots \otimes T_{j_k}^{i_k}$$

with implicit summation on $i_1, \ldots, i_k, j_1, \ldots, j_k$ and where the $I_i$ are isomorphism classes of finite dimensional $H$-modules and the coefficients $(\Lambda_{i_1 \ldots i_k})^{i_1 \ldots i_k} \in \mathbb{C}$ are all zero except a finite number of them. This can be written more conveniently as $f = \sum_{i_1, \ldots, i_k} \text{tr}(\Lambda_{i_1 \ldots i_k} T^i \otimes \ldots \otimes T^j)$ where the matrices $\Lambda_{i_1 \ldots i_k} \in \text{End}_\mathbb{C}(I_1 \otimes \ldots \otimes I_k)$ are all zero except a finite number of them. We define

$$W^f(L) = \sum_{i_1, \ldots, i_k} \text{tr}(\Lambda_{i_1 \ldots i_k} (T^i \otimes \ldots \otimes T^j) \text{hol}_{i_1 \ldots i_k}(L)) \in \mathcal{L}_{g,n}(H)$$

where $\text{hol}_{i_1 \ldots i_k}(L)$ is the holonomy of the based link whose components are colored by $I_1, \ldots, I_k$. In terms of the Hennings formulation, we see thanks to (38) that it holds

$$W^f(L) = (\text{id} \otimes f)(\text{Hen}(L)).$$

We denote by $\text{Inv}_k(H)$ the subspace of multilinear forms which are invariant under an iterated coadjoint action:

$$\text{Inv}_k(H) = \{ f \in (H^\circ)^{\otimes k} \mid \forall h \in H, f(S(h^{(2k)})h^{(2k-1)}, \ldots, S(h^{(2)})h^{(1)}) = \varepsilon(h)f \}$$

where the “?” are the positions of the variables. In particular $\text{Inv}_1(H)$ is the subspace of symmetric linear forms:

$$\text{Inv}_1(H) = \text{SLF}(H) = \{ \varphi \in H^\circ \mid \forall x, y \in H, \varphi(xy) = \varphi(yx) \}.$$

Proposition 4.10. We have the following properties

1. $f \in \text{Inv}_k(H) \Rightarrow W^f(L) \in \mathcal{L}_{g,n}^{\text{inv}}(H)$, where $L$ is a based link with $k$ basepoints.

2. $W^f(L)W^{f'}(L') = W^{f \otimes f'}(L \ast L').$

3. For $n = 0$ and any $j \in \text{MCG}(\Sigma_{g,h}^0)$, $j(W^f(L)) = W^f(j(L)).$

4. Any element of $\mathcal{L}_{g,n}(H)$ can be written $W^f(L)$ for some $f \in (H^\circ)^{\otimes k}$ and some based link $L$ with $k$ basepoints ($k, f, L$ are non-unique).

5. Any element of $\mathcal{L}_{g,n}^{\text{inv}}(H)$ can be written $W^f(L)$ for some $f \in \text{Inv}_k(H)$ and some based link $L$ with $k$ basepoints ($k, f, L$ are non-unique).

Proof. 1. Write $\text{Hen}(L) = Z_0 \otimes Z_1 \otimes \ldots \otimes Z_k$. Then thanks to (39):

$$W^f(L) : h = (Z_0 \cdot h) f(Z_1, \ldots, Z_k) = Z_0 f(S^2(h^{(1)})Z_1S(h^{(2)}), \ldots, S(h^{(2k-1)})Z_kS(h^{(2k)}))$$

$$= Z_0 f(S(h^{(1)})Z_1S(h^{(2k-1)}), \ldots, S(h^{(2)})Z_kS(h^{(1)}))$$

$$= Z_0 \varepsilon(h)f(Z_1, \ldots, Z_k) = \varepsilon(h)W^f(L).$$
2. Follows immediately from Theorem 4.4.
3. Follows immediately from Theorem 4.5.
4. Let \( x \in \mathcal{L}_{g,n}(H) \). Thanks to the defining relations of \( \mathcal{L}_{g,n}(H) \) (Definition 2.1), it is clear that any element of \( \mathcal{L}_{g,n}(H) \) can be written as a linear combination of some products of the form

\[
\begin{align*}
I_1 B(1)_{j_1}^i A(1)_{k_1}^{i_1} \cdots I_g B(g)_{j_g}^i A(g)_{k_g}^{i_g} M(g+1)_{m_1}^{i_1} \cdots M(g+n)_{m_n}^{i_n}.
\end{align*}
\]

To avoid cumbersome notations, take for instance \((g,n) = (1,1)\). Then we can write

\[
\begin{align*}
x &= \sum_{I,J,K} (\Lambda_{I,J,K} I^{i_1} \otimes J^{j_1} \otimes K^{k_1} A_{i_1}^{k_1} B_{j_1}^{i_1} M_{k_1}^{i_1} = \sum_{I,J,K} \text{tr}(\Lambda_{I,J,K} I^{i} \otimes J^{j} \otimes K^{k} A_{i}^{k} B_{j}^{i} M_{k}^{i})
\end{align*}
\]

where only a finite number of the matrices \( \Lambda_{I,J,K} \in \text{End}_C(I \otimes J \otimes K) \) are non-zero, and inserting \( g \) is not an issue since it is invertible. Take \( f = \sum_{I,J,K} \text{tr}(\Lambda_{I,J,K} I^{i} \otimes J^{j} \otimes K^{k} A_{i}^{k} B_{j}^{i} M_{k}^{i}) \in (H^o)^{\otimes 3} \) and

By definition we have \( W^f(L) = x \).

5. Follows by combining the proofs of the properties 1 and 4. \( \square \)

Remark 4.11. Let \( L \) be the obvious generalization to any \( g,n \) of the based link used in the previous proof. Then we have shown that

\[
\begin{align*}
(H^o)^{\otimes (2g+n)} &\to \mathcal{L}_{g,n}(H), \quad f \mapsto W^f(L), \\
\text{Inv}_{2g+n}(H) &\to \mathcal{L}_{g,n}(H)^{\text{inv}}, \quad f \mapsto W^f(L)
\end{align*}
\]

are surjective linear maps. When \( H \) is finite dimensional and factorizable, we have \( \dim(\mathcal{L}_{g,n}(H)) = \dim(H)^{2g+n} \) (see [Fai19b, §3.3]) and by comparison of dimensions these maps are isomorphisms of vector spaces.

For a based link \( L \), we define its free isotopy class \([L]\) to be the result of the following operation (applied to all the basepoints):

By definition, \([L] \subset \Sigma_{g,n} \times [0,1]\) is a link in the usual sense. Recall that in the classical case, a Wilson loop does not depend on the basepoint, but only on the free isotopy class of the curve. In general, \( W^f(L) \) depends on the basepoint. If we want to remove this dependence, we must restrict \( f \) to be in a suitable subspace:

**Proposition 4.12.** Let \( L_1, L_2 \) be based links with \( k \) basepoints. If \( f \in \text{SLF}(H)^{\otimes k} \), then \( W^f \) depends only on the free isotopy class:

\[
[L_1] = [L_2] \implies W^f(L_1) = W^f(L_2).
\]
Proof. Thanks to the cyclicity of symmetric linear forms, it is clear that the basepoints in the diagram (37) can be moved at any generic point (i.e. not at a maximal, minimal or crossing point, nor in a handle) without changing the value of \((\id \otimes \varphi_1 \otimes \ldots \otimes \varphi_k)(\text{Hen}(L_i))\). Moreover, that the evaluation of the diagram (37) is unchanged under isotopy is a generalization of the corresponding fact for the Hennings invariant.

It follows that \(W^f\) makes sense for (usual) links if \(f \in \text{SLF}(H)\). More precisely, let \(\mathcal{L}(\Sigma_{g,n})\) be the set of isotopy classes of framed links in \(\Sigma_{g,n} \times [0,1]\) which are SLF(H)-colored (i.e. each connected component is labelled by a symmetric linear form). Let \(L \in \mathcal{L}(\Sigma_{g,n})\) be a link with \(k\) components and let \(L_b\) be any uncolored based link such that \([L_b] = L\), then we define

\[
W(L) = W^{\varphi_1 \otimes \ldots \otimes \varphi_k}(L_b)
\]

(40)

where \(\varphi_1, \ldots, \varphi_k\) are the colors of the components of \(L\).

**Definition 4.13.** We call \(W : \mathbb{C} \mathcal{L}(\Sigma_{g,n}) \to \mathcal{L}_{\text{inv}}(H)\) the generalized Wilson loop map, and an element \(W(L)\) is called a generalized Wilson loop.

By the second property in Proposition 4.10, the generalized Wilson loops form a subalgebra in \(\mathcal{L}_{\text{inv}}(H)\).

**Remark 4.14.** Recall that the character of a finite dimensional \(H\)-module \(I\) is \(\chi_I = \text{tr}(I)\). Let \(L^x\) be an unbased link whose all strands are colored by characters \(\chi^{I_1}, \ldots, \chi^{I_k}\) and \(L\) be the same link without coloring. Then

\[
W(L^x) = \text{hol}^{I_1, \ldots, I_k}(L)
\]

and we recover the Wilson loop map defined in [Fai19c, Chap. 6]. Indeed, it suffices to consider the case where there is only one strand. Let \(L_b\) be a based link such that \([L_b] = L\). By definition \(W(L^x) = \text{tr}_q(\text{hol}^I(L_b))\). Hence according to (33) and (22), we have:

\[
W(T_{\bar{L}_b}) = \text{tr}_q(I) = \text{hol}^I(D_{\bar{L}_b}) = \text{hol}^I(L)
\]

\[
W(T_{\bar{L}_b}) = \text{tr}_q(I) = \text{hol}^I(D_{\bar{L}_b}) = \text{hol}^I(D_L)
\]

where \(T_{\bar{L}_b}\) is the part of \(L_b\) outside a small neighborhood of the basepoint, \(D_{\bar{L}_b}\) is the corresponding diagram obtained when applying \(\text{hol}^I\) and \(D_L\) is the free isotopy diagram of \(D_{\bar{L}_b}\).

5 Relationship with stated skein algebras

Recall the definition 4.1 of \(\partial \Sigma\)-tangles, which is just a slight generalization of [Le16, §2.3]. In this section and as in [Le16, CL19], we will consider \(\partial \Sigma\)-tangles which are uncolored and unoriented. Recall from [Le16, §2.5] that the stated skein algebra \(\mathcal{S}_q(\Sigma)\) of a punctured bordered surface \(\Sigma\) is the \(\mathbb{Z}[q^{1/2}, q^{-1/2}]\)-module freely generated by the (isotopy classes of) \(\partial \Sigma\)-tangles on that surface, modulo the Kauffman relations:

\[
\begin{align*}
\otimes &= q \otimes + q^{-1} \otimes \\
\text{O} &= -(q^2 + q^{-2}) \emptyset
\end{align*}
\]

(41)
and the boundary relations:

\[
\begin{align*}
+ & \quad = q^{1/2} \\
- & \quad = q^{-2} \\
+ & \quad + q^{1/2} \\
0 & \quad = 0 \\
0 & \quad = 0
\end{align*}
\]

The conventions for the figures are the same as in [Le16, CL19]. However, we stress that our convention for the stack product (Definition 1.3) is opposite to that of [Le16, CL19]; in other words, the stated skein algebras considered here have opposite multiplication to those in these papers.

In this section we work with \( H = U_{q^2} = U_{q^2}(\mathfrak{sl}_2) \), the quantum group associated to \( \mathfrak{sl}_2(\mathbb{C}) \) with ground ring \( \mathbb{Z}[q^{1/2}, q^{-1/2}] \), where \( q \) is a formal parameter or a complex number which is not a root of unity. Let \( \mathcal{O}_{q^2} = \mathcal{O}_{q^2}(\mathfrak{sl}_2) \) be the restricted dual of \( U_{q^2} \) with its canonical Hopf algebra structure. The goal of this section is to show that the holonomy map provides an isomorphism of \( \mathbb{Z} \)-algebras between \( \mathcal{S}^g(\Sigma_{g,n}) \) and \( \mathcal{L}_{g,n}(U_{q^2}) \). We recall that \( \Sigma_{g,n}^{g,n} \) is the surface \( \Sigma_{g,n} \setminus D \) (where \( D \) is an open disk) with one point removed on its boundary (Figure [1]), where \( \Sigma_{g,n} \) is the compact oriented surface of genus \( g \) with \( n \) punctures. We begin with useful preliminary remarks.

Let \( V_2 \) be a 2-dimensional \( \mathbb{C} \)-vector space with basis \( (v_-, v_+) \). \( V_2 \) can be endowed with an \( U_{q^2} \)-module structure, called the fundamental representation of \( U_{q^2} \). The action is given by:

\[
\begin{align*}
Ev_+ &= 0, \\
Fv_+ &= v_-, \\
Kv_+ &= q^2v_-, \\
Kv_- &= q^{-2}v_+
\end{align*}
\]

It is well-known that every finite dimensional simple \( U_{q^2} \)-module is a direct summand of some tensor power \( V_2^{\otimes N} \). It follows that \( \mathcal{O}_{q^2} \) is generated as an algebra by the matrix coefficients \( V_2 \) of \( V_2 \) (with \( s, t \in \{ \pm \} \)). This also applies to the algebra \( \mathcal{L}_{g,n}(U_{q^2}) \); indeed, let \( B(i) = \hat{V}_2 \), \( A(i) = \hat{A}(i) \), \( M(i) = \hat{M}(i) \). For any matrix \( X \in \mathcal{L}_{g,n}(U_{q^2}) \otimes \text{End}_\mathbb{C}(V_2) \), we denote by \( X_s^t \) \((s, t \in \{ \pm \})\) its components in the basis \((v_-, v_+)\):

\[
X = \begin{pmatrix} X_- & X_-
\end{pmatrix} = \begin{pmatrix} X_+ & X_+
\end{pmatrix}.
\]

Finally, let \( R \in \text{End}_\mathbb{C}(V_2)^{\otimes 2} \) be the \( R \)-matrix of \( U_{q^2} \) evaluated on \( V_2 \otimes V_2 \), and let \( R_{21} \) be the matrix defined by \( (R_{21})^{s_1 s_2}_{t_1 t_2} = R^{s_2 s_1}_{t_2 t_1} \). Explicitly:

\[
R = q^{-1} \begin{pmatrix} q^2 & 0 & 0 & 0 \\
0 & 1 & q^2 - q^{-2} & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & q^2 \\
\end{pmatrix}, \quad R_{21} = q^{-1} \begin{pmatrix} q^2 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & q^2 \\
\end{pmatrix}.
\]

**Lemma 5.1.** The algebra \( \mathcal{L}_{g,n}(U_{q^2}) \) is generated by the coefficients of the matrices \( B(i), A(i) \) for \( 1 \leq i \leq g \) and \( M(i) \) for \( g + 1 \leq i \leq g + n \), modulo the relations given by the following matrix identities:

\[
\begin{align*}
RX(i)_1 R_1 X(i)_2 &= X(i)_2 RX(i)_1 R_2, & \text{for } 1 \leq i \leq g + n, \\
X(i)_1 X(i)_2 + q^4 X(i)_1 X(i)_2 &= 1, & \text{for } 1 \leq i \leq g + n, \\
RB(i)_1 R_1 A(i)_2 &= A(i)_2 R B(i)_1 R^{-1}, & \text{for } 1 \leq i \leq g, \\
RX(i)_1 R^{-1} Y(j)_2 &= Y(j)_2 RX(i)_1 R^{-1}, & \text{for } 1 \leq i < j \leq g + n.
\end{align*}
\]

where \( X(i) \) is \( A(i) \) or \( B(i) \) if \( 1 \leq i \leq g \) and is \( M(i) \) if \( g + 1 \leq i \leq g + n \), and the same applies to \( Y(j) \). Recall that the meaning of the subscripts 1, 2 is explained after Definition 2.1.
Proof. Since any finite dimensional $U_q^\mathbb{C}$-module is a direct summand of some $V_2^\otimes N$, $N \in \mathbb{N}$, the fusion relation (5) implies the claim about the set of generators. It is well-known (see e.g. [BR19, Lemma 5.1]) that the fusion relation (5) with $I = J = V_2$ is equivalent to the two first lines of relations. The third and fourth lines of relations are just (6) and (7) with $I = J = V_2$.

As a result, we can without loss of generality restrict the color of all the strands in diagrams to be $V_2$, since any color can be recovered by cabling and inserting a Jones-Wenzl idempotent. Hence in this section, all the strands in diagrams are implicitly colored by $V_2$.

Another important property is that $V_2$ is self-dual. For our purposes we fix a particular isomorphism as follows:

$$D : V_2^* \xrightarrow{\sim} V_2$$

$$v^- \mapsto -q^{5/2} v_+ \quad i.e. \quad D = \begin{pmatrix} 0 & q^{1/2} \\ -q^{5/2} & 0 \end{pmatrix} \quad (44)$$

where $(v^-, v^+)$ is the dual basis of $(v_-, v_+)$. Recall that by definition of the $H$-module structure on $I^*$, it holds $I^* = \ell(S(I))$, where $\ell$ denotes the transpose and we recall that $\ell x$ means the representation of $x \in H$ on the finite dimensional $H$-module $I$. If we take $I = V_2$, we have $V_2^h D = D V_2^h$ and hence we deduce the following equality, which will be useful later:

$$\ell(h) = D^{-1} S^{-1}(h) D. \quad (45)$$

There exists a particular pivotal element $g$ lying in some completion of $U_q^\mathbb{C}$ (see [Tim15]) and satisfying

$$gv_- = -q^2 v_-, \quad gv_+ = -q^{-2} v_+$$

(of course $g \neq -K$). With this choice one can check that it holds

$$e \circ D^* = D \quad i.e. \quad \ell D = V_2^g D \quad (46)$$

where $e = e_{V_2} : V_2^* \xrightarrow{\sim} V_2$ is the identification with the bidual (3). This implies that the value of a diagram does not depend of the orientation of its closed components. Indeed:

$$\begin{align*}
\begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array} & = & \begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array}
\end{align*}$$

(we use (19) and the similar fact for cups and caps) and hence by inserting coupons $D$ and $D^{-1}$ on a strand we can change its orientation without changing the value of the diagram.

Remark 5.2. If one chooses the usual pivotal element $K$ instead of $g$, then (46) becomes $e \circ D^* = -D$ and the value of a diagram depends up to a sign of the orientation on its closed components, see [KM91, Lem 3.18], [Tim15]. This explains the choice of the less natural-looking pivotal element $g$.

According to these remarks, we define a non-oriented graphical calculus for $\mathcal{L}_{g,n} (U_q^\mathbb{C})$, with unoriented cups, caps, crossings and handles:

$$\begin{align*}
\begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array} & = & \begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array}
\end{align*}$$

$$\begin{align*}
\begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array} & = & \begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array}
\end{align*}$$

$$\begin{align*}
\begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array} & = & \begin{array}{ccc}
\begin{array}{c}
D
\end{array} & \begin{array}{c}
V_2
\end{array} & X \\
\begin{array}{c}
V_2
\end{array} & \begin{array}{c}
D
\end{array} & X
\end{array}
\end{align*}$$

26
The explicit values of these unoriented graphical elements are:

\[
X = \begin{pmatrix}
q^{1/2}X_+ & -q^{3/2}X_- & q^{1/2}X_+ & -q^{3/2}X_-
\end{pmatrix}
\cup
\begin{pmatrix}
0 & -q^{5/2} & q^{1/2} & 0
\end{pmatrix}
\cap
\begin{pmatrix}
0 & q^{-1/2} & -q^{-5/2} & 0
\end{pmatrix}
\]

\[
\begin{pmatrix}
0 & -q^{5/2} & q^{1/2} & 0
\end{pmatrix}
\]

\[
\begin{pmatrix}
0 & q^{-1/2} & -q^{-5/2} & 0
\end{pmatrix}
\]

\[
PR = \begin{pmatrix}
0 & q^{-1/2} & -q^{-5/2} & 0
\end{pmatrix}
\]

where \(P\) is the flip tensor \(P_{kl}^i = \delta^i_k\delta^j_l\), the \(X_s\) (with \(s, t \in \{\pm\}\)) are the components of the matrix \(X = \tilde{X}\) and \(R\) is the \(R\)-matrix (43). More generally, a handle containing several unoriented strands is obviously defined by putting a coupon \(D\) on each strand of the oriented version, and the associated explicit value is computed thanks to the fusion relation (43). The values (47) extend in the usual way to an evaluation map \(Z\) of diagrams. When \(Z\) is restricted to tangles (diagrams without handles), it is just an unoriented version of the Reshetikhin-Turaev functor for \(U_q^2\)-colored framed tangles. It is well-known that \(Z\) satisfies the Kauffman bracket skein relation (41). Let us record for further use that by definition

\[
Z(\bigotimes)_{ik} = R_{ij}^{ki}, \quad Z(\bigcap)_{ij} = (R^{-1})_{ij}^{ik}
\]

where \(i, j, k, l \in \{\pm\}\).

Let us now proceed with preliminary remarks about stated skein algebras. By (42) we have

\[
\begin{pmatrix}
0 & -q^{5/2} & q^{1/2} & 0
\end{pmatrix}
\]

\[
\begin{pmatrix}
0 & q^{-1/2} & -q^{-5/2} & 0
\end{pmatrix}
\]

More generally, it is shown in [CL19, §5] that

\[
\epsilon
\begin{pmatrix}
\cdots & \cdots & \cdots & \cdots
\end{pmatrix}
\]

\[
T
\begin{pmatrix}
\cdots & \cdots & \cdots & \cdots
\end{pmatrix}
\]

\[
\begin{pmatrix}
0 & -q^{5/2} & q^{1/2} & 0
\end{pmatrix}
\]

\[
\begin{pmatrix}
0 & q^{-1/2} & -q^{-5/2} & 0
\end{pmatrix}
\]

where \(s_i, t_i \in \{\pm\}\) are states. The left-hand side of this figure represents an element of the stated skein algebra of the bigon \(\mathcal{B}\) (with \(T\) any tangle), \(\epsilon : S_q^s(\mathcal{B}) \to Z[q^{1/2}]\) denotes the counit of \(S_q^s(\mathcal{B})\) [CL19, §3.4] and \(Z\) is the evaluation map defined by (47).

As explained in [CL19, §3.2], cutting out a bigon \(\mathcal{B}\) from a boundary edge \(e\) of a punctured bordered surface \(\mathcal{S}\) and applying the splitting theorem [Le16, Th. 3.1] yields a morphism \(\Delta_e : S_q^s(\mathcal{S}) \to S_q^s(\mathcal{B}) \otimes S_q^s(\mathcal{S})\) which is a \(S_q^s(\mathcal{B})\)-comodule-algebra structure on \(S_q^s(\mathcal{S})\) (see [CL19, Fig. 7]). An important fact for our purposes is that the equality \((\epsilon \otimes \text{id}) \circ \Delta_e = \text{id}\) (which is one of the axioms of a comodule) together with (48) allows us to prove relations in \(S_q^s(\mathcal{S})\) in a graphical way.

Let us illustrate this in the case of \(S_q^s(\mathcal{B})\). Consider the following matrix \(T \in S_q^s(\mathcal{B}) \otimes \text{End}_C(V_2)\) (here \(V_2\) is just considered as a vector space):

\[
T = \begin{pmatrix}
T_- & T_- & T_+ & T_+
\end{pmatrix}, \quad \text{with } T^s_t = \begin{pmatrix}
\end{pmatrix}
\]

\((s, t \in \{\pm\}\) are states). First, observe that
\[ \mathcal{O}_q \]
Theorem 5.3. The map $\text{hol}^s$ descends to an isomorphism of $O_{q^2}$-comodule-algebras:

$$S_q^s(\Sigma_{g,n}^{0,\bullet}) \cong \mathcal{L}_{g,n}(U_{q^2}).$$

Proof. We first show that $\text{hol}^s$ is well-defined, i.e. that it preserves the defining relations of $S_q^s(\Sigma_{g,n}^{0,\bullet})$. It is clear that $\text{hol}^s$ is compatible with the Kauffman bracket skein relations (41) since so does the unoriented graphical calculus for $U_{q^2}$. For the boundary relations (42), we have

$$\text{hol}^s \left( \begin{array}{c}
\begin{array}{c}
\circ \\
\circ
\end{array}
\end{array} \right) = v^s \otimes v^t(\cup) = \cup^{st}$$

$$\text{hol}^s \left( \begin{array}{c}
\begin{array}{c}
\begin{array}{c}
\circ \\
\circ
\end{array}
\end{array} - q^{-2} \begin{array}{c}
\begin{array}{c}
\circ \\
\circ
\end{array}
\end{array} - q^{1/2} \begin{array}{c}
\begin{array}{c}
\circ \\
\circ
\end{array}
\end{array}
\end{array} \right) (v_s \otimes v_t)$$

$$= (v^- \otimes v^+ - q^{-2}v^+ \otimes v^- - q^{1/2}v^+ \otimes v^-)(v_s \otimes v_t) = \delta_s^+ \delta_t^+ - q^{-2} \delta_s^+ \delta_t^- - q^{1/2}(-q^{-5/2} \delta_s^+ \delta_t^- + q^{-1/2} \delta_s^- \delta_t^+) = 0$$

for all $s, t \in \{\pm\}$, as desired.

The fact that $\text{hol}^s$ is an algebra morphism follows immediately from Theorem 4.4. To show that it is an isomorphism, we will use the following facts:

$$S_q^s(\Sigma_{g,n}^{0,\bullet}) \cong S_q^s(\Sigma_{1,0}^{0,\bullet}) \otimes S_q^s(\Sigma_{0,1}^{0,\bullet}) \otimes S_q^s(\Sigma_{g,n}^{0,\bullet}),$$

$$\mathcal{L}_{g,n}(U_{q^2}) \cong \mathcal{L}_{1,0}(U_{q^2}) \otimes \mathcal{L}_{0,1}(U_{q^2})$$

where $\otimes$ is the braided tensor product of algebras in the category of left $O_{q^2}$-comodules. The first isomorphism follows from the glueing theorem for stated skein algebras [CL19 Th. 4.13]. The second isomorphism is a well-known and general fact about the algebras $\mathcal{L}_{g,n}(H)$ ([AS96], §3.2], also see [Fai19b, §3.2]). Hence to show that $\text{hol}^s$ is an isomorphism, it is enough to show it for the surfaces $\Sigma_{g,n}^{0,\bullet}$ and $\Sigma_{1,0}^{0,\bullet}$, which is done in the two next subsections. The fact that $\text{hol}^s$ is a morphism of $O_{q^2}$-comodules also follows from the corresponding fact for these two building blocks.

Remark 5.4. I learned from the referee that T. Lê announced independently in some conferences (in particular Paris, October 2019) that stated skein algebras are isomorphic to $\mathcal{L}_{g,n}(U_{q^2})$, with a sketch of the proof. This result is also mentioned in his preprint with Yu [LY20], which appeared shortly after the present work.

Let $U^{(b_i)}_s$, $U^{(a_i)}_s$, $U^{(m_j)}_s$ (with $s, t \in \{\pm\}$) be the $\partial\Sigma$-tangles naturally associated to the generators $b_i, a_i, m_j$ of $\pi_1(\Sigma_{g,n})$ represented in Figure [1]

These elements can be arranged as matrices $U^{(b_i)}_s$, $U^{(a_i)}_s$, $U^{(m_j)}_s \in S_q^s(\Sigma_{g,n}^{0,\bullet}) \otimes \text{End}_C(V_2)$, and by definition it holds

$$\text{hol}^s(U^{(b_i)}_t) = B(i)^tD, \quad \text{hol}^s(U^{(a_i)}_t) = A(i)^tD, \quad \text{hol}^s(U^{(m_j)}_t) = M(j)^tD$$

(51)

where obviously $\text{hol}^s(U^{(b_i)}_t)^t = \text{hol}^s(U^{(b_i)}_t^t)$. Thanks to Lemma 3.1 we obtain a presentation by generators and relations of $S^s_q(\Sigma_{g,n}^{0,\bullet})$. 

29
Corollary 5.5. The algebra $S_q^\circ(\Sigma_{g,n}^\circ)$ is generated by the coefficients of the matrices $U^{(h)}, U^{(n)}$ for $1 \leq i \leq g$ and $U^{(m)}$ for $g + 1 \leq i \leq g + n$, modulo the relations obtained by replacing $B(i)$ with $U^{(h)}(D)^{-1}$, $A(i)$ with $U^{(n)}(D)^{-1}$ and $M(i)$ with $U^{(m)}(D)^{-1}$ in the relations of Lemma 5.4.

The (usual) skein algebra $S_q(\Sigma_{g,n})$ is the subalgebra of $S_q^\circ(\Sigma_{g,n}^\circ)$ consisting of linear combinations of closed links (tangles without boundary points and hence without states). On this subalgebra, $hol^s$ is simply the Wilson loop map $W$ with all the strands colored by $\chi_2^+$, the character of $V_2$. By [BFK98a, Th. 10] (see also [BR19, Th. 8.4] for the statement of this result in the formalism used here), the map $W$ provides an isomorphism from $S_q(\Sigma_{g,n})$ to the subalgebra of invariant elements $L_{g,n}^{inv}(U_q^t)$. Hence:

Corollary 5.6. The (usual) skein algebra $S_q(\Sigma_{g,n})$ is exactly the subalgebra of invariant elements of the $O_q$-comodule-algebra $S_q^\circ(\Sigma_{g,n}^\circ)$.

5.1 Proof for $\Sigma_{0,1}^\circ$ 

Let

$$M = M = \begin{pmatrix} m^- & m_+^- \\ m_+^- & m_+^+ \end{pmatrix} \in L_{0,1}(U_q^t) \otimes \textnormal{End}_C(V_2).$$

Then by Lemma 5.1, $L_{0,1}(U_q^t)$ is generated by the 4 coefficients of the matrix $M$, modulo the following relations:

$$RM_1R_{21}M_2 = M_2RM_1R_{21}, \quad \text{qdet}(M) = 1 \tag{52}$$

where by definition the quantum determinant is $\text{qdet}(M) = M^-M_+^- - q^4M_+^+M_+^+.$

For $l \geq 0$ and $s_1, \ldots, s_l, t_1, \ldots, t_l \in \{\pm\},$ we define the following elements of $S_q^\circ(\Sigma_{0,1}^\circ)$:

$$U(l)_{s_1\ldots s_l}^{t_1\ldots t_l} =$$

(for $l = 0$ this is $U(0) = 1$, namely the empty diagram). Note that for a fixed $l$, these elements can be arranged into a tensor $U(l) \in S_q^\circ(\Sigma_{0,1}^\circ) \otimes \textnormal{End}_C(V_2)^{\otimes l}$. For simplicity we denote $U = U(1)$ and $V = U(2)$; in a matrix form these tensors are written as

$$U = U(1) = \begin{pmatrix} U^- & U_+^- \\ U_-^+ & U_+^+ \end{pmatrix}, \quad V = U(2) = \begin{pmatrix} V^- & V_+^- & V_-^- & V_+^+ \\ V_+^- & V^- & V_+^+ & V_-^+ \\ V_-^+ & V_+^+ & V^- & V_+^- \\ V_+^+ & V_-^+ & V_+^- & V^- \end{pmatrix}.$$

As explained previously, we use the $(S_q^\circ(\mathcal{B}) = O_q$)-comodule-algebra structure of stated skein algebras together with id $= (\varepsilon \otimes \text{id}) \circ \Delta$ and (48) to derive equalities graphically. Here we apply this to the dashed arc $e$ depicted below.

$$= \sum_{i_1, \ldots, i_l, j_1, \ldots, j_l} \varepsilon_{i_1, \ldots, i_l; j_1, \ldots, j_l} U(l)_{j_1\ldots j_l}^{i_1\ldots i_l}$$

$$= \sum_{i_1, \ldots, i_l, j_1, \ldots, j_l} Z(T)_{s_1\ldots s_k; j_1, \ldots, j_l}^{i_1, \ldots, i_l; j_1, \ldots, j_l} U(l)_{j_1\ldots j_l}^{i_1\ldots i_l} \tag{53}$$
where the summation indices are all in \( \{\pm\} \). This equality implies in particular that the collection of elements \( U(l)_{i_{j_{1}}^{1} \cdots j_{l}} \) (with \( l \geq 0 \) and \( i_{\eta}, j_{\eta} \in \{\pm\} \) for each \( \eta \)) spans \( S_{q}(\Sigma_{0,1}^{0}) \) as a \( \mathbb{Z}[q^{\pm 1/2}] \)-module.

Since \( \mathcal{L}_{0,1}(U_{q^{2}}) \) is isomorphic to the braided dual of \( U_{q^{2}} \) \cite[§4]{BR}, we can deduce the following lemma from \cite[Prop. 4.17]{CL}, where it is shown that \( S_{q}^{\ast}(\Sigma_{0,1}^{0}) \) is isomorphic to the braided dual. Our proof is however different.

**Lemma 5.7.** 1. We have a morphism \( j : \mathcal{L}_{0,1}(U_{q^{2}}) \rightarrow S_{q}^{\ast}(\Sigma_{0,1}^{0}) \) of \( O_{q^{2}} \)-comodule-algebras defined by \( j(M) = U(tD)^{-1} \). Explicitly:

\[
\begin{pmatrix}
  j(M_{-}) & j(M_{+}) \\
  j(M_{+}) & j(M_{-})
\end{pmatrix} = \begin{pmatrix}
  q^{-5/2}U_{+} & -q^{-1/2}U_{-} \\
  q^{-5/2}U_{-} & -q^{-1/2}U_{+}
\end{pmatrix}.
\]

2. The morphism \( j \) is surjective.

**Proof.** 1. We will show that the relations (52) defining \( \mathcal{L}_{0,1}(U_{q^{2}}) \) are satisfied. This is entirely based on formal matrix computations. Using the product in \( S_{q}^{\ast}(\Sigma_{0,1}^{0}) \) and (53), we obtain:

\[
U_{t_{1}}^{s_{1}}U_{t_{2}}^{s_{2}} = \sum_{ijkl} V_{ij}^{kl} Z(\begin{pmatrix}
  \sigma_{1t_{1}} & \sigma_{2t_{2}}
\end{pmatrix})_{ijkl} = \sum_{jklm} V_{ij}^{kl} R_{j_{m}k_{l}} R_{k_{l}m_{j}}
\]

\[
= \sum_{jklm} (a_{\beta})^{s_{2}} V_{ij}^{kl} (t_{b_{\beta}}_{m})^{j} (t_{b_{\beta}}_{l})^{k} (t_{a_{\alpha}}_{m})^{l} (t_{a_{\alpha}}_{l})^{k}
\]

where we wrote \( R = a_{\eta} \otimes b_{\eta} \) with implicit summation and implicit representation on the fundamental representation \( V_{2} \) (i.e. \( R \) is the matrix in (43)). Hence

\[
U_{1}U_{2} = (a_{\beta})_{2} V (t_{b_{\beta}})_{1} (t_{b_{\beta}})_{1} (t_{a_{\alpha}})_{2}
\]

where as usual the subscript 1, 2 indicate the two canonical embeddings of \( S_{q}^{\ast}(\Sigma_{0,1}^{0}) \otimes \text{End}_{C}(V_{2}) \) in \( S_{q}^{\ast}(\Sigma_{0,1}^{0}) \otimes \text{End}_{C}(V_{2}) \otimes 2 \). Now we compute:

\[
U_{1}U_{2} = (a_{\beta})_{2} V D_{1}^{-1} S^{-1}(b_{\alpha})_{1} S^{-1}(b_{\beta})_{1} D_{1} D_{2}^{-1} S^{-1}(a_{\alpha})_{2} D_{2}
\]

\[
= (a_{\beta})_{2} V D_{1}^{-1} D_{2}^{-1} (b_{\alpha})_{1} S^{-1}(b_{\beta})_{1} (a_{\alpha})_{2} D_{1} D_{2}
\]

\[
= (a_{\beta})_{2} V D_{1}^{-1} D_{2}^{-1} (b_{\alpha})_{1} g_{1} S(b_{\beta})_{1} g_{2}^{-1} S^{2}(a_{\alpha})_{2} g_{2} D_{1} D_{2}
\]

\[
= (a_{\beta})_{2} V D_{1}^{-1} g_{1}^{-1} D_{2}^{-1} S^{2}(a_{\alpha})_{2} g_{2} D_{1} D_{2}
\]

\[
= (a_{\beta})_{2} V (tD)^{-1} R_{21} S(b_{\beta})_{1} (tD_{1}) R_{21}^{-1}
\]

For the first equality we used (45), for the second we used \( (S \otimes S)(R) = R \) and obvious commutation relations between tensors, for the third and the fourth we used (2) (here \( g \) implicitly means \( V_{2} \)) and obvious commutation relations between tensors, and for the fifth we used (46). Thanks to the relation \( a_{\gamma} \otimes S(b_{\beta}) b_{\gamma} = 1 \otimes 1 \) we can invert this equality, which gives

\[
V(tD)^{-1} (tD_{1})^{-1} = (U(tD)^{-1})_{1} R_{21} (U(tD)^{-1})_{2} R_{21}^{-1}
\]

(54)

Now since

\[
\begin{pmatrix}
  s_{1} & s_{2} & t_{1} & t_{2}
\end{pmatrix}
\]

\[
\begin{pmatrix}
  s_{1} & s_{2} & t_{1} & t_{2}
\end{pmatrix}
\]
we obtain thanks to relation (53) that \( \sum_{ij} R_{ij}^{st} v_{t2t1}^{ij} = \sum_{ij} V_{ji}^{st} R_{ij}^{t1}, \) that is \( R_{21} v_{21} = v(1) b_1 a_2. \) Then, relations (45) and \((S \otimes S)(R) = R \) yields \( R_{21} v_{21} d_2^{-1} d_1^{-1} = v d_1^{-1} d_2^{-1} R_{21}. \) Finally, we multiply this equality by \( g_1^{-1} g_2^{-1} \) and we use the relations \( R_{1} g_2 = g_1 g_2 R \) and (40):

\[
R_{21} v_{21} (\delta d_2^{-1} (\delta d_1^{-1} R_{21} = v (\delta d_1^{-1} (\delta d_2^{-1} R_{21}.
\]

This last equality together with (54) gives the first equality of (52):

\[
R (U (\delta d_1^{-1}) R_{21} (U (\delta d_1^{-1}) = (U (\delta d_1^{-1}), \quad R (U (\delta d_1^{-1})_1 R_{21}.
\]

In order to obtain the quantum determinant relation, observe that

And then (53) gives \( \sum_{ij} V_{ij}^{st} \cap_{ji} = \cup_{ji}, \) which can be rewritten as \( V^{l}(P \cap) = \cup, \) where \( P_{ij} = \delta_{ij} \) is the flip tensor. Moreover, a computation reveals that \( (P \cap) = (\delta d_1^{-1} (\delta d_2^{-1} \cup. \) Hence, by (54) we have

\[
(U (\delta d_1^{-1})_1 R_{21} (U (\delta d_1^{-1}) = (U (\delta d_1^{-1})_1 R_{21} \cup = \cup.
\]

Expanding this matrix equality in components gives only one new relation, which is precisely \( \text{qdet}(U (\delta d_1^{-1}) = 1. \) Hence \( j \) is a morphism of algebras. Let us show that it is a morphism of \( \mathcal{O}_{q^2} \)-comodules (recall that we identify \( \mathbb{S}^q \) with \( \mathcal{O}_{q^2} \)). By definition of the coaction of \( \mathcal{O}_{q^2} \) on \( \mathbb{S}^q (\Sigma_{0,1}) \), we have

\[
\Delta_{s}(U_s^j) = \sum_{i} T_{i}^{s} T_{j}^{t} \otimes U_j.
\]

Let us identify \( U_{i}^{j} \) (resp. \( T_{i}^{j} \)) with \( 1 \otimes U_{i}^{j} \) (resp. \( T_{i}^{j} \otimes 1 \)); then we get

\[
\Delta_{s}(U) = T U T. \]

By (45) and (46), it holds \( T = D^{-1} S^{-1}(T) D = D^{-1} s(T) g D = D^{-1} T \) and hence

\[
\Delta_{s} \circ j(M) = \Delta_{s}(U) (\delta d_1^{-1} = T U T (\delta d_1^{-1} = T (U (\delta d_1^{-1}) S(T) = (j \otimes id) \circ \Omega(M)
\]

where \( \Omega \) is the coaction (10) on \( L_{0,1}(U_{q^2}). \)

2. Observe that

\[
U_{s}^{s_1} U_{s}^{s_2} = \sum_{i_{j_1}, \ldots j_{k}} Z(\sigma) s_{1}^{i_{1}} \ldots s_{l}^{i_{l}} s_{l}^{i_{l}} U(l)_{i_{1}}^{j_{1}} \ldots U(l)_{i_{l}}^{j_{l}}
\]

where the handle contains a bunch of \( l \) parallel strands and \( \sigma \in B_{2n} \) is some braid (it can be computed explicitly but we do not need it). By (53), it follows that

\[
U_{s}^{s_1} U_{s}^{s_2} = \sum_{i_{j_1}, \ldots j_{k}} Z(\sigma) s_{1}^{i_{1}} \ldots s_{l}^{i_{l}} s_{l}^{i_{l}} U(l)_{i_{1}}^{j_{1}} \ldots U(l)_{i_{l}}^{j_{l}}
\]
But σ is a braid, so that \( Z(\sigma) \) is an invertible matrix, and hence we can invert these relations and write any element \( U(l)_{i_1,...,i_t}^{s_1,...,s_t} \) as a linear combination of the monomials \( U_{t_1}^{s_1} \ldots U_{t_l}^{s_l} \). The claim is proved since, as already observed, the collection of elements \( U(l)_{i_1,...,i_t}^{s_1,...,s_t} \) spans \( S_q^o(\Sigma_{0,1}^\bullet) \) as a \( \mathbb{Z}[q^{\pm 1/2}] \)-module.

**Lemma 5.8.** The map \( \text{hol}^o : S_q^o(\Sigma_{0,1}^\bullet) \to \mathcal{L}_{0,1}(U_q^o) \) is an isomorphism of \( \mathcal{O}_q^o \)-comodule-algebras.

**Proof.** Thanks to [51], we have \( \text{hol}^o \circ j = \text{id} \). It follows that \( j \) is injective and it is surjective by Lemma 5.7. Hence it is an isomorphism of \( \mathcal{O}_q^o \)-comodule-algebras, with inverse \( \text{hol}^o \).

### 5.2 Proof for \( \Sigma_{1,0}^o \)

Let

\[
B = \frac{V_2}{B} = \begin{pmatrix} B^- & B_1^+ \\ B_1^- & B^+ \end{pmatrix}, \quad A = \frac{V_2}{A} = \begin{pmatrix} A^- & A_1^- \\ A_1^+ & A^+ \end{pmatrix} \in \mathcal{L}_{1,0}(U_q^o) \otimes \text{End}_C(V_2).
\]

Then by Lemma 5.1, \( \mathcal{L}_{1,0}(U_q^o) \) is generated by the 8 coefficients of the matrices \( B \) and \( A \), modulo the following relations:

\[
\begin{align*}
RB_{12}B_1 & = B_2 RB_{12}, & B^- B_1^+ - q^4 B_1^- B^+ & = 1 \\
RA_1R_{21}A_2 & = A_2 RA_1R_{21}, & A^- A_1^+ - q^4 A_1^- A^+ & = 1
\end{align*}
\]  
(55)

As previously, for \( l \geq 0 \) and \( s_1, \ldots, s_t, t_1, \ldots, t_l \in \{ \pm \} \) we define the following elements of \( S_q^o(\Sigma_{1,0}^\bullet) \):

\[
U(l)^{(b)}_{t_1 \ldots t_l}^{s_1 \ldots s_t} = \ldots \quad \text{and} \quad U(l)^{(a)}_{t_1 \ldots t_l}^{s_1 \ldots s_t} = \ldots
\]

These elements can be arranged into tensors \( U(l)^{(b)} \), \( U(l)^{(a)} \in S_q^o(\Sigma_{1,0}^\bullet) \otimes \text{End}_C(V_2)^{\otimes l} \). For simplicity we denote \( U^{(b)} = U(1)^{(b)} \), \( U^{(a)} = U(1)^{(a)} \). We have the analogue of [53]:

\[
\sum Z(T_{br}^{i_1 \ldots i_n j_1 \ldots j_m}^{i_1' \ldots i_n' j_1' \ldots j_m'}) U(l)^{(b)}_{j_1 \ldots j_m} U(m)^{(a)}_{j_1' \ldots j_m'} = \ldots
\]

with \( T_{br} = \ldots \)

\[
(56)
\]

where the sum is over all the indices \( i_q, i'_q, j_q, j'_q \), each one ranging in \( \{ \pm \} \). To obtain this relation, one applies as before the equality \( \text{id} = (\varepsilon \otimes \text{id}) \circ \Delta_e \) and (48) to the dashed arc \( e \) in the figure below, which gives a bigon and another copy of \( \Sigma_{1,0}^\bullet \).
where we force the apparition of the product \( U(l)^{(b)}_{j_1...j_l} U(m)^{(a)}_{j_1'...j_m'} \) using isotopy; this explains why we have \( T' \) instead of \( T \) in the right-hand side of (56). In particular, (56) implies that the collection of elements \( U(l)^{(b)}_{j_1...j_l} U(m)^{(a)}_{j_1'...j_m'} \) (with \( l, m \geq 0 \) and \( i_j, j_i, i_j', j_j' \in \{ \pm \} \) for each \( \eta \)\) spans \( S_q^t(\Sigma_{1,0}^*) \) as a \( Z[q^{\pm 1/2}] \)-module.

The next result is the exact analogue of Lemma 5.7.

**Lemma 5.9.** 1. We have a morphism \( j : \mathcal{L}_{1,0}(U_{q^2}) \to S_q^t(\Sigma_{1,0}) \) of \( \mathcal{O}_{q^2} \)-comodule-algebras defined by \( j(B) = U^{(b)}(D)^{-1} \) and \( j(A) = U^{(a)}(D)^{-1} \). Explicitly:

\[
\begin{pmatrix}
    j(B^-) & j(B^+) \\
    j(B^+) & j(B^-)
\end{pmatrix} = \begin{pmatrix}
    q^{-5/2}U^{(b)}_+ & -q^{-1/2}U^{(b)}_- \\
    q^{-5/2}U^{(b)}_- & -q^{-1/2}U^{(b)}_+
\end{pmatrix}, \quad \begin{pmatrix}
    j(A^-) & j(A^+) \\
    j(A^+) & j(A^-)
\end{pmatrix} = \begin{pmatrix}
    q^{-5/2}U^{(a)}_+ & -q^{-1/2}U^{(a)}_- \\
    q^{-5/2}U^{(a)}_- & -q^{-1/2}U^{(a)}_+
\end{pmatrix}.
\]

2. The morphism \( j \) is surjective.

**Proof.** 1. The proof is again entirely based on formal matrix computations. It is clear that the two first lines of relations in (55) are satisfied, since it suffices to repeat the proof of Lemma 5.7 in each handle with the matrices \( U^{(b)}, U^{(a)} \) instead of \( U \). To show the exchange relation (third line of (55)), observe that by (56):

\[
U^{(a)}_{t_1} U^{(b)}_{t_2} = \sum_{ijkl} U^{(b)}_j U^{(a)}_k Z_{ijkl}
\]

The evaluation of the braid gives the following expression:

\[
U^{(a)}_1 U^{(b)}_2 = \left( a_i a_j \ U^{(b)}_{t b^i \ t a^j} \right)_{S(\alpha)} \left( b^\gamma S(\alpha) \ U^{(a)}_{t b^\gamma \ t b^i} \right)_{\Sigma_{1,0}^*} R \left( U^{(b)}(D)^{-1} \right)_1 R_2 \left( U^{(a)}(D)^{-1} \right)_2 = \left( U^{(a)}(D)^{-1} \right)_2 R \left( U^{(b)}(D)^{-1} \right)_1 R^{-1}
\]

as desired.

2. By repeating the proof of the second claim of Lemma 5.7 in each handle, we know that we can write any element \( U(l)^{(b)}_{j_1...j_l} \) (resp. \( U(m)^{(a)}_{j_1'...j_m'} \)) as a polynomial in the 4 elements \( U^{(b)}_{t} \) (resp. \( U^{(a)}_{t'} \)), with \( s, t, s', t' \in \{ \pm \} \). Hence any element \( U(l)^{(b)}_{j_1...j_l} U(m)^{(a)}_{j_1'...j_m'} \) can be written as a polynomial in the 8 elements \( U^{(b)}_{t}, U^{(a)}_{t'} \). The claim is proved since, as already observed, this collection of elements spans \( S_q^t(\Sigma_{1,0}^*) \) as a \( Z[q^{\pm 1/2}] \)-module. \( \square \)

**Lemma 5.10.** The map \( \text{hol}^t : S_q^t(\Sigma_{1,0}^*) \to \mathcal{L}_{1,0}(U_{q^2}) \) is an isomorphism of \( \mathcal{O}_{q^2} \)-comodule-algebras.

**Proof.** Completely similar to the proof of Lemma 5.8. \( \square \)
6 Geometric interpretation of the vacuum representation of \( \mathcal{L}_{g,0}(H) \) on \( \mathcal{L}_{0,g}(H) \)

In this section we take \( n = 0 \). Let \( \mathcal{L}_{g,0}^{A}(H) \) be the subalgebra of \( \mathcal{L}_{g,0}(H) \) generated by all the coefficients \( A(i)^{k}_{l} \) of the matrices \( A(i) \) (for all \( i \) and all the finite dimensional \( H \)-modules \( I \)). We define a right action \( \triangleright \) of \( \mathcal{L}_{g,0}^{A}(H) \) on \( \mathbb{C} \) by

\[
\forall i, \quad 1 \triangleright A(i) = I_{\text{dim}(I)} \quad (\text{i.e. } 1 \triangleright A(i)^{k}_{l} = \delta^{k}_{l}).
\]

It is immediate that \( \triangleright \) is compatible with the relations \([5], [7]\) of Definition \([2.1]\). Hence we have a representation \( \mathbb{C}_{\text{vac}} \) of \( \mathcal{L}_{g,0}^{A}(H) \). 1 is called a vacuum vector or a cyclic vector, often denoted \( \Omega \) or \( |0\rangle \) (see for instance [AS96a, Thm. 21], but with different conventions than here). Then we define the right vacuum representation of \( \mathcal{L}_{g,0}(H) \) to be the induced representation

\[
\mathbb{C}_{\text{vac}} \otimes \mathcal{L}_{g,0}(H)
\]

where \( \mathcal{L}_{g,0}^{A}(H) \) acts by left multiplication on \( \mathcal{L}_{g,0}(H) \). Thanks to the defining relations of \( \mathcal{L}_{g,0}(H) \) (Definition \([2.1]\)), it is clear that any element of \( \mathcal{L}_{g,0}(H) \) can be written as a linear combination of some products of the form

\[
A(1)^{l_{1}}_{i_{1}} \ldots A(g)^{l_{g}}_{i_{g}} B(1)^{j_{1}}_{j_{1}} \ldots B(g)^{j_{g}}_{j_{g}}.
\]

Hence, any element in the vacuum representation is a linear combination of vectors of the form

\[
1 \triangleright B(1)^{j_{1}}_{j_{1}} \ldots B(g)^{j_{g}}_{j_{g}}.
\]

Similarly, any element of \( \mathcal{L}_{0,g}(H) \) can be written as a linear combination of some products of the form \( M(1)^{l_{1}}_{j_{1}} \ldots M(g)^{l_{g}}_{j_{g}} \), and we have an isomorphism of vectors spaces

\[
\mathbb{C}_{\text{vac}} \otimes \mathcal{L}_{g,0}(H) \rightarrow \mathcal{L}_{0,g}(H)
\]

\[
1 \triangleright B(1)^{j_{1}}_{j_{1}} \ldots B(g)^{j_{g}}_{j_{g}} \rightarrow I_{l_{1}}^{l_{1}} \ldots I_{l_{g}}^{l_{g}} \mathcal{L}_{0,g}(H);
\]

By identification of these two spaces we obtain the (right) vacuum representation of \( \mathcal{L}_{g,0}(H) \) on \( \mathcal{L}_{0,g}(H) \); we again denote the action by \( \triangleright \).

Remark 6.1. We consider a right representation because we want to relate it to the stacking representation of \( \mathcal{C}(\Sigma_{g,0}^{\bullet}) \) on \( \mathcal{C}(\Sigma_{0,g}^{\bullet}) \), which is a right representation due to our convention on the stack product (Definition \([4.3]\)).

Lemma 6.2. The vacuum representation of \( \mathcal{L}_{g,0}(H) \) on \( \mathcal{L}_{0,g}(H) \) is explicitly given by
and

\[ I_1 M(1) \cdots I_g M(g) A(j) \]

The left-hand side of the first equality means of course \( (I_1 M(1) \cdots I_g M(g) A(j)) \otimes u_1 \otimes u^k \otimes \cdots \otimes v_l \otimes v^m \otimes w_n \otimes w^o \), and similarly for the second.

Proof. These are just the outcomes of graphical computations. For instance, below is the computation for the action of \( A(1) \) in the case \( g = 2 \). Other cases are treated similarly.

We used (25), (24) and the definition of the vacuum representation.

Remark 6.3. There is a left representation of \( \mathcal{L}_{g,0}(H) \) on \( (H^\circ)^{\otimes g} \) which comes from the facts that there exists [Ale94] a morphism of algebras \( \mathcal{L}_{g,0}(H) \to \mathcal{H}(\mathcal{O}(H))^{\otimes g} \) (the Heisenberg double of the dual Hopf algebra \( \mathcal{O}(H) \)) and that there is a natural representation of \( \mathcal{H}(\mathcal{O}(H)) \) on \( H^\circ \). When \( H \) is finite dimensional and factorizable, the morphism \( \mathcal{L}_{g,0}(H) \to \mathcal{H}(\mathcal{O}(H))^{\otimes g} \) is an isomorphism [Fai19b] §3.3], and it is well-known that when \( H \) is finite dimensional \( \mathcal{H}(\mathcal{O}(H)) \cong \text{End}_C(H^\circ) \). Hence under these assumptions, \( \mathcal{L}_{g,0}(H) \) has only one indecomposable left representation, namely \( (H^\circ)^{\otimes g} \), which is necessarily dual to the vacuum (right) representation on \( \mathcal{L}_{0,0}(H) \). Note however that writing down an explicit intertwiner is not obvious (one has to use certain elements defined in [Fai19b] which implement the action of the mapping class group). I do not know if these two representations are isomorphic when \( H \) is infinite dimensional.
Recall that we denote by $\mathcal{T}(\Sigma_{g,n}^\bullet)$ the set of isotopy classes of $H$-colored $\partial\Sigma$-tangles, with $\Sigma = \Sigma_{g,n}^\bullet \times [0,1]$, and by $\mathcal{C}_{\mathcal{T}}(\Sigma_{g,n}^\bullet)$ the $\mathbb{C}$-vector space with basis $\mathcal{T}(\Sigma_{g,n}^\bullet)$. Then $\mathcal{C}_{\mathcal{T}}(\Sigma_{g,n}^\bullet)$ is an algebra for the stack product. There is a right representation of $\mathcal{C}_{\mathcal{T}}(\Sigma_{g,0}^\bullet)$ on $\mathcal{C}_{\mathcal{T}}(\Sigma_{0,g}^\bullet)$ obtained by stacking $\Sigma_{g,0}^\bullet \times [0,1]$ atop $\Sigma_{0,g}^\bullet \times [0,1]$; we denote it by $\triangleright$. Note that it is a right representation due to our convention for the stack product (Definition 4.3).

For $x \otimes v \in \mathcal{L}_{0,g}(H) \otimes V$ and $y \otimes w \in \mathcal{L}_{g,0}(H) \otimes W$, where $V,W$ are finite dimensional $H$-modules, we define
\[
(x \otimes v) \triangleleft (y \otimes w) = (x \triangleright y) \otimes v \otimes w \in \mathcal{L}_{0,g}(H) \otimes V \otimes W.
\]
We also denote by $\text{hol}_{0,g}$ and $\text{hol}_{g,0}$ the holonomy maps for $\mathcal{C}_{\mathcal{T}}(\Sigma_{0,g}^\bullet)$ and $\mathcal{C}_{\mathcal{T}}(\Sigma_{g,0}^\bullet)$ respectively (see Definition 4.2). The following result relates the representations $\triangleleft$ and $\triangleright$.

**Theorem 6.4.** For $S \in \mathcal{C}_{\mathcal{T}}(\Sigma_{0,g}^\bullet)$ and $T \in \mathcal{C}_{\mathcal{T}}(\Sigma_{g,0}^\bullet)$ it holds
\[
\text{hol}_{0,g}(S) \triangleleft \text{hol}_{g,0}(T) = \text{hol}_{0,g}(S \triangleright T).
\]

**Proof.** The representation $\triangleright$ is depicted in Figure 4 for the case $g = 2$ (which is completely representative of the general situation). For simplicity, we omitted the orientations and the colorings in this figure; moreover even if we draw only one strand in each handle for $S$ and $T$, this represents in fact bunches of parallel strands. To obtain $S \triangleright T$, use the embeddings of the fat graphs in the more intuitive views of the surfaces $\Sigma_{2,0}^\bullet$ and $\Sigma_{0,2}^\bullet$ (see Figure 2); it is more easy to perform the stacking from this viewpoint. The theorem follows from the comparison between Figure 4 and the diagrammatic formulas in Lemma 6.2. Note that in Figure 4 we have presented $S \triangleright T$ in such a way that the comparison is immediate; in particular the two crossings just below the coupon $T$ correspond to the crossings which appear when we apply $\text{hol}_{2,0}$ to $T$ (Definition 4.2).

**Corollary 6.5.** The subspace $\mathcal{L}_{0,g}^{\text{inv}}(H)$ is stable under the action of $\mathcal{L}_{g,0}^{\text{inv}}(H)$:
\[
x \in \mathcal{L}_{0,g}^{\text{inv}}(H), \ y \in \mathcal{L}_{g,0}^{\text{inv}}(H) \Rightarrow x \triangleleft y \in \mathcal{L}_{0,g}^{\text{inv}}(H).
\]
Proof. Thanks to the fifth property in Proposition 4.10 write $x = W^{f_1}(L_1)$ (resp. $y = W^{f_2}(L_2)$), where the based link $L_1$ (resp. $L_2$) has $k$ (resp. $l$) basepoints and $f_1 \in \text{Inv}_k(H)$ (resp. $f_2 \in \text{Inv}_l(H)$). Then

$$x \otimes y = W^{f_1}(L_1) \otimes W^{f_2}(L_2) = W^{f_1 \otimes f_2}(L_1 \bowtie L_2).$$

But it is clear that $f_1 \otimes f_2 \in \text{Inv}_{k+l}(H)$ and thus by the first property in Proposition 4.10 this element is invariant.

Recall that $\mathcal{L}(\Sigma_{g,0}^\text{in})$ is the set of (isotopy classes of) SLF$(H)$-colored framed links in $\Sigma_{g,0}^\text{in} \times [0,1]$, and similarly for $\mathcal{L}(\Sigma_{g,0})$. The canonical embedding $j \times \text{id} : \Sigma_{g,0}^\text{in} \times [0,1] \to \Sigma_{g,0} \times [0,1]$ induces a surjective (non injective) linear map $\pi : \mathbb{C} \mathcal{L}(\Sigma_{g,0}^\text{in}) \to \mathbb{C} \mathcal{L}(\Sigma_{g,0})$. Also recall the generalized Wilson loop map $W$ defined in (10).

**Proposition 6.6.** Let $x \in \mathcal{L}_{0,g}^\text{in}(H)$ and $L_1, L_2 \in \mathbb{C} \mathcal{L}(\Sigma_{g,0}^\text{in})$. It holds

$$\pi(L_1) = \pi(L_2) \implies x \otimes W(L_1) = x \otimes W(L_2).$$

Hence for $L \in \mathbb{C} \mathcal{L}(\Sigma_{g,0})$, $x \otimes W(L)$ is well-defined.

**Proof.** Consider the SLF$(H)$-colored links $L, L^0$ depicted below:

![Diagram](image-url)

The dots mean the remaining of $\Sigma_{g,0}^\text{in} \times [0,1]$ (see Figure 2), where the links $L, L^0$ are equal. It is clear that two links $L_1, L_2$ satisfy $\pi(L_1) = \pi(L_2)$ if we can pass from one to another by this transformation. Thanks to the fifth property in Proposition 4.10 write $x = W^f(K)$ where the uncolored based link $K$ has $k$ basepoints and $f \in \text{Inv}_k(H)$. We use the Hennings formulation of holonomy (see §4.3). Let $L_b$ and $L_b^0$ be uncolored based links such that $[L_b] = L$ and $[L_b^0] = L^0$. The diagrams (as in (37)) associated to $K \bowtie L_b$ and $K \bowtie L_b^0$ are related as follows:

![Diagram](image-url)

This represents a neighborhood of the dotted line, and the remaining of the diagrams are equal. We number the basepoints of $L_b, L_b^0$ with primes to distinguish them from the basepoints of $K$. To avoid cumbersome computations, take $k = 2$ (this is completely representative of the general situation).

Write $\text{Hen}(K \bowtie L_b) = Z_0 \otimes Z_1 \otimes Z_2 \otimes Z_1' \otimes \ldots \otimes Z_1' \in \mathcal{L}_{g,n}(H) \otimes H^\otimes(2^{k+l})$, with implicit summation. Let $a_{i(1)} \otimes b_{i(1)}, \ldots, a_{i(8)} \otimes b_{i(8)}$ be $8 = 4k$ copies of $R = a_i \otimes b_i$ (one for each crossing in the diagram above), then

$$\text{Hen}(K \bowtie L_b^0) = Z_0 \otimes gS(a_{i(4)}b_{i(5)}g^{-1}Z_i^1b_{i(6)}S^2(a_{i(3)}) \otimes gS(a_{i(2)}b_{i(7)}g^{-1}Z_2^1b_{i(8)}S^2(a_{i(1)}))$$

$$\otimes gb_{i(1)}b_{i(2)}b_{i(3)}b_{i(4)}S(a_{i(5)}a_{i(6)}S(a_{i(7)}a_{i(8)}g^{-1}Z_1' \otimes Z_2' \otimes \ldots \otimes Z_1')$$

$$= Z_0 \otimes S^2(a_{i(4)}b_{i(5)}) Z_1 S(a_{i(3)}b_{i(6)}) \otimes S^2(a_{i(2)}b_{i(7)}) Z_2 S(a_{i(1)}b_{i(8)})$$

$$\otimes gS^{-1}(b_{i(4)}b_{i(3)}b_{i(2)}b_{i(1)}) S(a_{i(8)}a_{i(7)}a_{i(6)}a_{i(5)}) g^{-1}Z_1' \otimes Z_2' \otimes \ldots \otimes Z_1'$$

$$= Z_0 \otimes S^2(a_{i(1)}b_{i(1)}^1) Z_1 S(a_{i(2)}b_{i(2)}^2) \otimes S^2(a_{i(3)}b_{i(3)}^3) Z_2 S(a_{i(4)}b_{i(4)}^4)$$

$$\otimes gS^{-1}(b_i) S(a_j) g^{-1}Z_1' \otimes Z_2' \otimes \ldots \otimes Z_1'$
For the second equality we used the properties of \( S \), the formula \((S \otimes S)(R) = R \) and \([2]\), and for the third equality we used an iteration of the formulas \((\Delta \otimes \text{id})(R) = R_{13}R_{23} \), \((\text{id} \otimes \Delta)(R) = R_{13}R_{12} \).

Hence, denoting by \( \varphi_1, \ldots, \varphi_l \) the colors of the components of \( L, L' \), we have:

\[
  x \triangleleft W(L^0) = Wf(K) \triangleleft W^{\varphi_1 \otimes \cdots \otimes \varphi_l}(L_b^0) = Wf^{\otimes \varphi_1 \otimes \cdots \otimes \varphi_l}(K \triangleleft L_b^0)
  = Z_0 f \left( S^2 \left( a_l^{(1)} b_l^{(1)} \right) Z_1 S \left( a_l^{(2)} b_l^{(2)} \right) \otimes S^2 \left( a_l^{(3)} b_l^{(3)} \right) Z_2 S \left( a_l^{(4)} b_l^{(4)} \right) \right)
  \varphi_1 \left( \left( g S^{-1} (b_i) S (a_i) g^{-1} Z'_i \right) \varphi_2(Z'_i) \ldots \varphi_l(Z'_i) \right)
  = Z_0 f \left( Z_1 \otimes Z_2 \right) \varphi_1(Z'_i) \ldots \varphi_l(Z'_i)
  = W^{f \otimes \varphi_1 \otimes \cdots \otimes \varphi_l}(K \triangleleft L_b) = Wf(K) \triangleleft W^{\varphi_1 \otimes \cdots \otimes \varphi_l}(L_b) = x \triangleleft W(L).
\]

For the second and sixth equalities we used Theorem \([6.4]\) and for the fourth equality we used that \( f \in \text{Inv}_k(H) \) and that \((\varepsilon \otimes \text{id})(R) = (\text{id} \otimes \varepsilon)(R) = 1\).

This proposition shows that we have a representation of \( \mathbb{C} \mathcal{L}(\Sigma_{g,0}) \) (and not just of \( \mathbb{C} \mathcal{L}(\Sigma_{g,0} \setminus D) \)) on \( \mathcal{L}_{0,g}^{\text{inv}}(H) \). Hence in some sense, the disc \( D \) is glued back via this process and we can deal with the closed surface \( \Sigma_{g,0} \).

Let us specialize these results to \( H = U_{p^2} = U_{p^2}(\mathfrak{sl}_2) \), where they descend to the skein algebra (quotient of \( \mathbb{C} \mathcal{L}(\Sigma_{g,0}) \) by skein relations). As already said (before Corollary \([5.6]\)), in that case we can without loss of generality color all the link components by \( \chi^\pm_{2} \) and we have two isomorphisms

\[
  W_{g,0} : \mathcal{S}_q(\Sigma_{g,0}^o) \xrightarrow{\sim} \mathcal{L}_{0,g}^{\text{inv}}(U_{q^2}), \quad W_{0,g} : \mathcal{S}_q(\Sigma_{0,g}) \xrightarrow{\sim} \mathcal{L}_{0,g}^{\text{inv}}(U_{q^2}).
\]

Moreover, there is a natural representation of \( \mathcal{S}_q(\Sigma_{g,0}) \) on \( \mathcal{S}_q(\Sigma_{0,g+1}) = \mathcal{S}_q(\Sigma_{0,g+1}) \) (skein module of a handlebody) obtained by stacking, we still denote it by \( \triangleleft \).

**Corollary 6.7.** Under the identifications \([57]\), the representation \( \triangleleft \) of \( \mathcal{L}_{0,g}^{\text{inv}}(U_{q^2}) \) on \( \mathcal{L}_{0,g}^{\text{inv}}(U_{q^2}) \) is the stacking representation \( \triangleleft \) of \( \mathcal{S}_q(\Sigma_{g,0}) \) on \( \mathcal{S}_q(\Sigma_{g,0}) \). In other words:

\[
  W_{0,g}(L_1) \triangleleft W_{g,0}(L_2) = W_{0,g}(L_1 \triangleleft L_2).
\]

### 7 A remark on roots of unity

Corollary \([6.7]\) is a bit disappointing because it tells us that the representation of \( \mathcal{S}_q(\Sigma_{g,0}) \) produced by combinatorial quantization is just equivalent to the obvious representation on the skein module of a handlebody. This changes dramatically if we replace the formal variable \( q \) by a root of unity \( \varepsilon \) and we will now describe a construction producing much less obvious representations of \( \mathcal{S}_q(\Sigma_{g,0}) \), which are moreover finite dimensional.

Let \( \varepsilon = e^{i \pi/2p} \) be a \( 4p \)-th root of unity \((p \geq 2)\), and let \( U_{\varepsilon} \) be the specialization of \( U_{q^2}(\mathfrak{sl}_2) \) to \( e^2 = e^{i \pi/p} \). Then we can consider the restricted quantum group of \( \mathfrak{sl}_2 \), denoted by \( \overline{U}_{\varepsilon} = \overline{U}_{\varepsilon}(\mathfrak{sl}_2) \), which is the quotient of \( U_{\varepsilon} \) by

\[
  E^p = F^p = 0, \quad K^{2p} = 1.
\]

The algebra \( \mathcal{L}_{g,n}(U_{\varepsilon}) \) does not exist since \( U_{\varepsilon} \) is not braided. Nevertheless, we can consider the specialization \( \mathcal{L}_{g,n}(U_{q^2})_{\varepsilon} \) of \( \mathcal{L}_{g,n}(U_{q^2}) \) at \( q^2 = \varepsilon^2 \) (this specialization is studied in great detail in \([BR19]\) for \( g = 0 \)). Moreover, it is possible to define \( \mathcal{L}_{g,n}(\overline{U}_{\varepsilon}) \) (see \([Fa19] \) §6 for full details), and it turns out it is the quotient of \( \mathcal{L}_{g,n}(U_{\varepsilon})_{\varepsilon} \) by

\[
  (X(i)_{\varepsilon})^p = (X(i)_{\varepsilon})^p = 0, \quad (X(i)_{\varepsilon})^{2p} = 1
\]

where as usual \( X(i) \) is \( A(i) \) or \( B(i) \) if \( 1 \leq i \leq g \) and is \( M(i) \) if \( g + 1 \leq i \leq g + n \) (recall Lemma \([5.1]\) from which we take back the notations). This together with the relations of Lemma \([5.1]\) gives a presentation by generators and relations of \( \mathcal{L}_{g,n}(\overline{U}_{\varepsilon}) \). The dimension of \( \mathcal{L}_{g,n}(\overline{U}_{\varepsilon}) \) is \((2p^2)^{2g+n}\).
Let \( W_e : S_e(\Sigma^o_{g,n}) \rightarrow \mathcal{L}^\text{inv}_{g,n}(U_{q^e})_{\mathbb{C}^2} \) be the specialization of the Wilson loop map (we recall that all the strands in \( S_e(\Sigma^o_{g,n}) \) are implicitly colored by the character \( \chi_2^+ \) of the fundamental representation \( V_2 \)) and let \( \overline{W} \) be the Wilson loop map for \( H = U_{\mathbb{C}^2} \) (with source the SLF(\( U_{\mathbb{C}^2} \)) colored links and with values in \( \mathcal{L}^\text{inv}_{g,n}(U_{\mathbb{C}^2}) \), according to Definition 4.13); note that we choose \( g = K^{p+1} \) for the pivotal element in \( U_{\mathbb{C}^2} \). The representation \( V_2 \) descends to \( U_{\mathbb{C}^2} \), so that \( \chi_2^+ \in \text{SLF}(U_{\mathbb{C}^2}) \). If we restrict \( \overline{W} \) to \( S_e(\Sigma^o_{g,n}) \) (i.e. we restrict \( \overline{W} \) to the links colored by \( \chi_2^+ \)), then \( \overline{W} \) factors through \( W_e \):

\[
S_e(\Sigma^o_{g,n}) \xrightarrow{W} \mathcal{L}^\text{inv}_{g,n}(U_{\mathbb{C}^2}) \quad \xrightarrow{pr} \quad \mathcal{L}^\text{inv}_{g,n}(U_{q^e})_{\mathbb{C}^2}
\]

where \( pr \) is the canonical projection. The restriction of \( pr \) to \( \mathcal{L}^\text{inv}_{g,n}(U_{q^e})_{\mathbb{C}^2} \) (specialization of \( \mathcal{L}^\text{inv}_{g,n}(U_{q^e}) \) at \( e^2 \)) takes values in \( \mathcal{L}^\text{inv}_{g,n}(U_{\mathbb{C}^2}) \) (but note that this restriction is not surjective). By the results of the previous section, we obtain an action of \( L \in S_e(\Sigma^o_{g,0}) \) on \( x \in \mathcal{L}^\text{inv}_{0,g}(U_{\mathbb{C}^2}) \) by

\[
x \omega \mapsto \overline{W}(L)
\]

and this produces a finite dimensional right representation of \( S_e(\Sigma^o_{g,0}) \).

In the sequel we describe explicitly this representation in the case of the torus \( \Sigma_{1,0} \). Consider the following curves in \( \Sigma^o_{0,1} \times \{0\} \subset \Sigma^o_{0,1} \times [0,1] \) and in \( \Sigma_{1,0} \times \{0\} \subset \Sigma_{1,0} \times [0,1] \) respectively:

Since \( U_{\mathbb{C}^2} \) is factorizable, we know by [Fa19, Lem. 3.9] that we have an isomorphism of algebras

\[
\text{SLF}(U_{\mathbb{C}^2}) \cong \mathcal{L}^\text{inv}_{0,1}(U_{\mathbb{C}^2}), \quad \varphi \mapsto \overline{W}^\varphi(m).
\]

where \( \overline{W}^\varphi(m) \) is the value of \( \overline{W} \) on \( m \) colored by \( \varphi \). Recall that \( \text{SLF}(U_{\mathbb{C}^2}) \) is a commutative algebra, for the usual product of linear forms \( \varphi \psi = (\varphi \otimes \psi) \circ \Delta \) (this is true for any finite dimensional factorizable ribbon Hopf algebra \( H \); actually for such \( H \) one has \( \text{SLF}(H) \cong \mathcal{Z}(H) \cong \mathcal{L}^\text{inv}_0(H) \)).

According to [BP99], \( S_e(\Sigma_{1,0}) \) is generated by the links \( a \) and \( b \). Hence, to describe the representation it suffices to compute the action of \( \overline{W}(a) = \overline{W}^{\chi_2^+}(a) \) and \( \overline{W}(b) = \overline{W}^{\chi_2^-}(b) \) on \( \overline{W}^\varphi(m) \). Recall that the Casimir element is \( C = FE + \frac{e^2 K + e^{-2} K^{-1}}{(e^2 - e^{-2})^2} \in \mathcal{Z}(U_{\mathbb{C}^2}) \).

**Lemma 7.1.** For all \( \varphi \in \text{SLF}(H) \), it holds

\[
\overline{W}^\varphi(m) \triangleleft \overline{W}(a) = \overline{W}^{\varphi(\triangle)}(m), \quad \overline{W}^\varphi(m) \triangleleft \overline{W}(b) = \overline{W}^{\varphi \chi_2^+}(m)
\]

where \( c = (e^2 - e^{-2})^2 C \), \( \varphi(\triangle) \) is defined by \( h \mapsto \varphi(hc) \) and \( \chi_2^+ \) is the product of the linear forms \( \varphi \) and \( \chi_2^+ \).

**Proof.** Thanks to Lemma 6.2 we have

\[
\begin{align*}
I \triangleleft \overline{W}(a) &= I \triangleleft \overline{W}(a) = I \triangleleft I \\
\overline{W}(V_2) &= \overline{W}(V_2) = \overline{W}(I) \\
\overline{W}(V_2) &= \overline{W}(V_2) = \overline{W}(I) \quad I (\chi_2^+ \otimes T)((g \otimes 1)RR')
\end{align*}
\]
where the last equality is obtained by a straightforward computation. Using the formula for $R$ \cite{FGST06} §4, we get that $(\chi^+_2 \otimes \text{id})((g \otimes 1)R') = c$, and hence $\bar{M} \triangleleft \bar{W}(a) = \bar{M}I$. Thus if we let 
\[ \varphi = \sum_i \text{tr}(\Lambda_i T), \]
\[ \bar{W}^\varphi(m) \triangleleft \bar{W}(a) = \sum_i \text{tr}(\Lambda_i \bar{g} \bar{M} \triangleleft \bar{W}(a)) = \sum_i \text{tr}(\Lambda_i \bar{g} \bar{M}I) = \bar{W}^{\varphi(\varphi)}(m). \]

For $b$, it is clear by definition of $\triangleleft$ that $\bar{M} \triangleleft \bar{W}(b) = \bar{M}\bar{W}X^1(\bar{m})$, which implies $\bar{W}^\varphi(m) \triangleleft \bar{W}(b) = \bar{W}^\varphi(m)\bar{W}X^1(\bar{m})$. But due to \eqref{eq:58} it holds $\bar{W}^\varphi(m)\bar{W}X^1(\bar{m}) = \bar{W}^{\varphi^2}(m). \square$

To simplify notations, we identify $\text{SLF}(\bar{U}_2)$ and $L_{\omega_1}(\bar{U}_2)$ through the isomorphism \eqref{eq:58}, so that we obtain a representation of $S_v(\Sigma_{1,0})$ on $\text{SLF}(\bar{U}_2)$. Recall that $\dim(\text{SLF}(\bar{U}_2)) = 3p - 1$, and we have the GTA basis \cite{GT09, Ari10}, here we use notations from \cite{Fai18}:

\[ \chi_1^+, \chi_1^-, \ldots, \chi_p^+, \chi_p^-, G_1, \ldots, G_{p-1}. \]

The $\chi_s^\pm$ are the characters of the simple modules $X^\pm(s)$ (in particular $X^+(2) = V_2$) and the $G_s$ are certain linear combinations of matrix coefficients of projective modules. It is easy to compute the action of $a$ ($\varphi \triangleleft \bar{W}(a) = \varphi(\varphi(b))$) on these elements:

\[ \chi_s^\alpha \triangleleft \bar{W}(a) = -\alpha(\epsilon^s + \epsilon^{-2s})\chi_s^\alpha, \quad G_s \triangleleft \bar{W}(a) = -(\epsilon^s + \epsilon^{-2s})G_s - (\epsilon^s - \epsilon^{-2s})(\chi_s^+ + \chi_{-s}^-) \]

where $\alpha \in \{\pm\}$. The action of $b$ ($\varphi \triangleleft \bar{W}(b) = \varphi(\chi^+_2)$) is given by the multiplication rules in the GTA basis \cite{GT09}, also see \cite{Fai18} for an elementary proof:

\[ \chi_1^\alpha \triangleleft \bar{W}(b) = \chi_2^\alpha, \quad \chi_s^\alpha \triangleleft \bar{W}(b) = \chi_{s-1}^\alpha + \chi_{s+1}^\alpha, \quad \chi_p^\alpha \triangleleft \bar{W}(b) = 2\chi_{p-1}^\alpha + 2\chi_1^\alpha, \]

\[ G_1 \triangleleft \bar{W}(b) = [2]G_2, \quad G_s \triangleleft \bar{W}(b) = \frac{s-1}{|s|}G_{s-1} + \frac{s+1}{|s|}G_{s+1}, \quad G_{p-1} \triangleleft \bar{W}(b) = [2]G_{p-2}. \]

where $[k] = \frac{\epsilon^{2k} - \epsilon^{-2k}}{\epsilon^2 - \epsilon^{-2}}$.

Let

\[ \mathcal{V}_1 = \text{vect}(\chi_s^+ + \chi_{-s}^+, \chi_s^-, \chi_{-s}^)_{1 \leq s \leq p-1}, \quad \mathcal{V}_2 = \text{vect}(\chi_s^+ + \chi_{-s}^-)_{1 \leq s \leq p-1}, \quad \mathcal{V}_3 = \text{vect}(G_s)_{1 \leq s \leq p-1} \]

so that $\text{SLF}(\bar{U}_2) = \mathcal{V}_1 \oplus \mathcal{V}_2 \oplus \mathcal{V}_3$. Note that $\mathcal{V}_1$ is the subspace generated by the characters of the projective modules. From the formulas above, we see that the structure of $\text{SLF}(\bar{U}_2)$ under the action of $S_v(\Sigma_{1,0})$ has the following shape:

\[ \mathcal{V}_2 \quad \mathcal{V}_3 \]

\[ \bar{W}(b) \quad \bar{W}(a) \quad \bar{W}(b) \]

By this diagram we mean that $\mathcal{V}_1$ is a submodule, that $\mathcal{V}_2 \triangleleft \bar{W}(a) \subset \mathcal{V}_2$, $\mathcal{V}_2 \triangleleft \bar{W}(b) \subset \mathcal{V}_1 + \mathcal{V}_2$ etc. Let

\[ J_1 = \mathcal{V}_1, \quad J_2 = \mathcal{V}_1 + \mathcal{V}_2, \quad J_3 = \mathcal{V}_1 + \mathcal{V}_2 + \mathcal{V}_3. \]

**Proposition 7.2.** $J_1 \subset J_2 \subset J_3$ is a composition series for $\text{SLF}(\bar{U}_2)$ under the action of $S_v(\Sigma_{1,0})$. Moreover, the composition factor $J_2/J_1$ is isomorphic to $S_v^{\text{red}}(\Sigma_{0,1}^0)$, the reduced skein module of the annulus (which is a $S_v(\Sigma_{1,0})$-module by stacking and reducing).
Proof. We must show that $J_1, J_2/J_1, J_3/J_2$ are irreducible. Recall that the center of $\overline{U}_2$ contains $p + 1$ primitive orthogonal idempotents $e_0, \ldots, e_p$, associated to the blocks of $\overline{U}_2$ [FGST06 Prop. 4.4.4]. They can be expressed as polynomials of $e$ [FGST06 Prop. D.1.1]: $e_0 = P_0(c), \ldots, e_p = P_p(c)$. Moreover, it is easy to see that

$$\chi_s^+ (? e_t) = \delta_{s,t} \chi_s^+, \quad \chi_s^- (? e_t) = \delta_{p-s,t} \chi_s^-, \quad G_s (? e_t) = \delta_{s,t} G_s.$$

Let us show that $J_1$ is irreducible. Let $0 \neq S \subset J_1$ be a submodule, and let $0 \neq \varphi = \lambda_0 \chi_p + \sum_s \lambda_s (\chi_s^+ + \chi_{p-s}) + \lambda_p \chi_p^+ \in S$. At least one of the coefficients, say $\lambda_s$, is non-zero. Then

$$\varphi \lhd P_s(\overline{W}(a)) = \varphi(P_s(c)) = \varphi(? e_s) = \lambda_s (\chi_s^+ + \chi_{p-s})$$

and thus $\chi_s^+ + \chi_{p-s} \in S$. Assume for instance $s = 1$. We have $(\chi_1^+ + \chi_{p-1}) \lhd \overline{W}(b) = (\chi_2^+ + \chi_{p-2}) + \chi_p$, and

$$((\chi_2^+ + \chi_{p-2}) + \chi_p) \lhd P_2(\overline{W}(a)) = \left( (\chi_2^+ + \chi_{p-2}) + \chi_p \right)(? e_2) = \chi_2^+ + \chi_{p-2},$$

$$((\chi_2^+ + \chi_{p-2}) + \chi_p) \lhd P_0(\overline{W}(a)) = \left( (\chi_2^+ + \chi_{p-2}) + \chi_p \right)(? e_0) = \chi_p$$

so that $\chi_2^+ + \chi_{p-2}, \chi_p \in S$. Continuing like this, one shows step by step that all the basis vectors are in $S$, and thus $S = J_1$ as desired. The proofs for $J_2/J_1$ and $J_3/J_2$ are similar.

For the last claim, recall that $S^\text{red}_S(\Sigma_0^1,1)$ is the quotient (in some sense) of $S(\Sigma_0^1,1)$ by the $(p-1)$-th Jones-Wenzl idempotent (see [Cos15 §6.5] for a survey) and that it is generated as a vector space by the “closures” $\text{cl}(f_n)$ of the Jones-Wenzl idempotents $f_n$ for $0 \leq n \leq p - 2$:

$$\text{cl}(f_n) = \ldots$$

We have $\overline{W}(\text{cl}(f_{s-1})) = \overline{W}^{\chi_s^+}(m)$, so that $\overline{W}(\text{cl}(f_{p-1})) + J_1 = \overline{W}^{\chi_s^+}(m) + J_1 = 0$ (where $x + J_1$ means the class of $x$ modulo $J_1$ and $\overline{W} : S^\text{red}_S(\Sigma_0^1,1) \to J_2/J_1$ is a well-defined map. Due to Theorem 6.4 we see that

$$\overline{W}(\text{cl}(f_{s-1})) \bullet L + J_1 = \overline{W}(\text{cl}(f_{s-1})) \lhd \overline{W}(L) + J_1 = \overline{W}^{\chi_s^+}(m) \lhd \overline{W}(L) + J_1$$

where $L \in S(\Sigma_1,0)$ and $\bullet$ is the stacking and reducing representation of $S(\Sigma_1,0)$ on $S^\text{red}_S(\Sigma_0^1,1)$. Thus $\overline{W} : S^\text{red}_S(\Sigma_0^1,1) \to J_2/J_1$ is an isomorphism of $S(\Sigma_1,0)$-modules.

Remark 7.3. In [Fai19c §6.5], we studied the left representation of $S(\Sigma_1,0)$ on the space mentioned in Remark 6.3 instead of on the vacuum representation space. Then the claim in [Fai19c Prop. 6.5.5], even if it is in agreement with the one in Proposition 7.2, does not make sense since we compare a left representation with the representation of $S(\Sigma_1,0)$ on $S^\text{red}_S(\Sigma_0^1,1)$ which is right due to our convention for the stack product (Definition 4.3); we did not realize this subtlety at that time. To make sense of it, one must take the dual representation, and apply the intertwiner mentioned in Remark 6.3.

It is very difficult to generalize to higher genus such an explicit description of the representation of $S(\Sigma,0)$ on $L^\text{inv}_{\Sigma,0}(\overline{U}_2)$. Indeed, by Remark 4.11 finding a basis of $L^\text{inv}_{\Sigma,0}(\overline{U}_2)$ is equivalent to finding a basis of $\text{Inv}_{2g}(\overline{U}_2)$ (multilinear forms invariant under the iterated coadjoint action), which is a difficult problem. Moreover, at roots of unity, generating sets of $S(\Sigma,0)$ are not known. However, we see from the previous result that the natural representation of $S(\Sigma,0)$ on $S^\text{red}_S(\Sigma_0^1,0)$ (which is known to be irreducible [BW10] will be a composition factor of the representation of $S(\Sigma,0)$ on $L^\text{inv}_{\Sigma,0}(\overline{U}_2)$ in a non-trivial way. Finally, the socle of this representation might be a generalization of the ideal formed by the characters of projective modules (which is the socle in the case of the torus, see $V_1$ above).
A Appendix: Proof of Theorem 4.4

The proof is purely diagrammatic but requires some preliminaries. The interested reader might find it relevant to study the proof on an example with small values of \( g, n \), like \( g = 2, n = 3 \). We begin with some notations:

\[
\begin{align*}
\beta_{0,1} = & \begin{array}{c}
\text{strip with } 1 \text{ strand} \\
\text{strip with } 0 \text{ strands}
\end{array} \\
\beta_{1,0} = & \begin{array}{c}
\text{strip with } 0 \text{ strand} \\
\text{strip with } 1 \text{ strands}
\end{array}
\end{align*}
\]

Note that up to using coupons we can assume that all the strands are positively oriented when they go through an handle and also that the bunch of strands in each handle is reduced to only one strand (colored by the tensor product of the colors). Hence we can assume the following form for \( T_1 \):

where the tangle \( T_1 \) is allowed to contain coupons. Similarly we can assume such a form for \( T_2 \), but with colors \( J_1, \ldots, J_{2g+n} \) instead of \( I_1, \ldots, I_{2g+n} \) and \( W_1, \ldots, W_l \) instead of \( V_1, \ldots, V_k \) and with some tangle \( T_2 \) instead of \( T_1 \). The product \( T_1 \ast T_2 \) then looks as follows:

where the braid \( \text{ex}_{g,n} \) (or rather its diagram) is constructed as follows. Let \([0,1]^3\) with coordinates \((x,y,z)\) and let \( \pi_{x} \) be the projection on the first coordinate. Let \( a_i, c_j \) be points in \([0,1] \times \{0\} \times \{0\}\) and let \( b_i, d_j \) be points in \([0,1] \times \{0\} \times \{1\}\), where \( 1 \leq i \leq g \) and \( 1 \leq j \leq n \), such that \( \pi_{x} \) has strictly increasing values on the following sequence:

\[
(a_1, b_1, a_2, b_2, \ldots, a_g, b_g, c_1, d_1, c_2, d_2, \ldots, c_n, d_n).
\]

Similarly, let \( \bar{a}_i, \bar{c}_j \) be points in \([0,1] \times \{1\} \times \{0\}\) and \( \bar{b}_i, \bar{d}_j \) be points in \([0,1] \times \{1\} \times \{1\}\), where \( 1 \leq i \leq g \) and \( 1 \leq j \leq n \), such that \( \pi_{x} \) has strictly increasing values on the following sequence:

\[
(\bar{a}_1, \ldots, \bar{a}_g, \bar{c}_1, \ldots, \bar{c}_n, \bar{b}_1, \ldots, \bar{b}_g, \bar{d}_1, \ldots, \bar{d}_n).
\]

Join the points \( a_i \) and \( \bar{a}_i \) (resp. \( b_i \) and \( \bar{b}_i, c_j \) and \( \bar{c}_j, d_j \) and \( \bar{d}_j \)) by straight lines and project the result on the \((x,y)\)-plane, this gives a braid diagram (we can always arrange the points \( a_i, b_i, c_j, d_j \) and
\[ \alpha_i, \bar{b}_i, c_j, \bar{d}_j \text{ so that the projection on } (x, y) \text{ has only simple or double points and we get a well-defined diagram.} \]  Finally, for each \( 1 \leq i \leq g \), replace the strand joining the points \( a_i \) and \( \bar{a}_i \) (resp. \( b_i \) and \( \bar{b}_i \)) by 4 parallel strands (4-cabling). Similarly, for each \( 1 \leq j \leq n \), replace the strand joining the points \( c_j \) and \( \bar{c}_j \) (resp. \( d_j \) and \( \bar{d}_j \)) by 2 parallel strands (2-cabling). This gives a braid diagram of \( \text{ex}_{g,n} \) in \([0, 1] \times [0, 1]\).

**Lemma A.1.** 1. The following equalities hold for all \( 1 \leq i \leq g \) and \( g + 1 \leq j \leq g + n \):

\[
\begin{align*}
&I_1 \quad I \quad J_1 \\
&J_{\oplus, j} \quad M(j) \\
&I_2 \quad J_2 \\
&I_1 \quad J_1 \\
&I \quad J \\
&I_2 \quad J_2
\end{align*}
\]

2. Let \( \alpha_1, \ldots, \alpha_g \) and \( \beta_1, \ldots, \beta_g \) be braids on 4 strands and let \( \gamma_1, \ldots, \gamma_n \) and \( \delta_1, \ldots, \delta_n \) be braids on 2 strands. It holds

\[
\text{ex}_{g,n} \circ (\alpha_1 \otimes \beta_1 \otimes \alpha_2 \otimes \beta_2 \otimes \ldots \otimes \alpha_g \otimes \beta_g \otimes \gamma_1 \otimes \delta_1 \otimes \gamma_2 \otimes \delta_2 \otimes \ldots \otimes \gamma_n \otimes \delta_n) = (\alpha_1 \otimes \ldots \otimes \alpha_g \otimes \gamma_1 \otimes \ldots \otimes \gamma_n \otimes \beta_1 \otimes \ldots \otimes \beta_g \otimes \delta_1 \otimes \ldots \otimes \delta_n) \circ \text{ex}_{g,n}.
\]

3. For \( k, l \geq 1 \), define

\[
\Gamma_{k,l} = (\text{id}^{\otimes (l-1)} \otimes c_{k,k} \otimes \text{id}_{k}^{\otimes (l-1)}) \circ (\text{id}^{\otimes (l-2)} \otimes c_{k,k}^{\otimes 2} \otimes \text{id}_{k}^{\otimes (l-2)}) \circ \ldots
\]

\[
\ldots \circ (\text{id}_{k}^{\otimes 2} \otimes c_{k,k}^{\otimes (l-2)} \otimes \text{id}_{k}^{\otimes 2}) \circ (\text{id}_{k}^{\otimes 2} \otimes c_{k,k}^{\otimes (l-1)} \otimes \text{id}_{k})
\]

where \( \text{id}_k = \text{id}^{\otimes k} \) is the identity braid on \( k \) strands; then

\[
\text{ex}_{g,n} = (\text{id}^{\otimes 4g} \otimes c_{4g,2n} \otimes \text{id}^{\otimes 2n}) \circ (\Gamma_{4g} \otimes \Gamma_{2,n}).
\]

**Proof.** 1. The first equality is readily equivalent to (23). The second equality is the outcome of a diagrammatic computation displayed in Figure 5 and based on (23) and (24).

2. This is obvious by definition of the braid \( \text{ex}_{g,n} \).

3. Let \( a'_i, c'_j \) be points in \([0, 1] \times \{\frac{1}{2}\} \times \{0\}\) and let \( b'_i, d'_j \) be points in \([0, 1] \times \{\frac{1}{2}\} \times \{1\}\), where \( 1 \leq i \leq g \) and \( 1 \leq j \leq n \), such that \( \pi_x \) has strictly increasing values on the following sequence:

\[
(a'_1, \ldots, a'_g, b'_1, \ldots, b'_g, c'_1, \ldots, c'_n, d'_1, \ldots, d'_n).
\]

Join the points \( a_i \) and \( a'_i \) (resp. \( b_i \) and \( b'_i \), \( c_j \) and \( c'_j \), \( d_j \) and \( d'_j \)) by straight lines and project the result on the \((x, y)\)-plane, this gives a braid diagram. For each \( 1 \leq i \leq g \), replace the strand joining the points \( a_i \) and \( a'_i \) (resp. \( b_i \) and \( b'_i \)) by 4 parallel strands (4-cabling); for each \( 1 \leq j \leq n \), replace the strand joining the points \( c_j \) and \( c'_j \) (resp. \( d_j \) and \( d'_j \)) by 2 parallel strands (2-cabling). This defines a braid diagram \( B_1 \) in \([0, 1] \times [0, \frac{1}{2}]\).

Similarly, join the points \( a'_i \) and \( a_i \) (resp. \( b'_i \) and \( b_i \), \( c'_j \) and \( c_j \), \( d'_j \) and \( d_j \)) by straight lines and project
the result on the \((x,y)\)-plane, this gives a braid diagram. For each \(1 \leq i \leq g\), replace the strand joining the points \(a'_i\) and \(\bar{a}_i\) (resp. \(b'_i\) and \(\bar{b}_i\)) by 4 parallel strands (4-cabling); for each \(1 \leq j \leq n\), replace the strand joining the points \(c'_j\) and \(\bar{c}_j\) (resp. \(d'_j\) and \(\bar{d}_j\)) by 2 parallel strands (2-cabling). This defines a braid diagram \(B_2\) in \([0,1] \times \left[\frac{1}{2},1\right]\).

Then it is not difficult to see that \(\text{ex}_{g,n} = B_2 \circ B_1, B_1 = \Gamma_{4g} \otimes \Gamma_{2n}, B_2 = \text{id}^\otimes_{4g} \otimes c_{4g,2n} \otimes \text{id}^\otimes_{2n}\) (it is helpful to draw some examples for small values of \(g,n\)).

---

Figure 5: Proof of the second equality in Lemma A.1.

The proof of Theorem 4.4 is now reduced to the diagrammatic computation displayed in Figure 6 on page 49, as we now explain. First note that by definition, the first diagram in this figure represents \(\text{hol}(T_1 * T_2)\) while the last diagram represents \(\text{hol}(T_1) \circ \text{hol}(T_2)\). The first equality is obtained by applying the first item in Lemma A.1 (1.) while the second equality is obtained thanks to the second and third items. For the third equality, observe first that due to the exchange relation (25) we have that for \(i < j\):
Using repeatedly this identity, we transform the tensor product of the handles labelled by

\[ B(1), \bar{A}(1), B(1), \bar{A}(2), B(2), \bar{A}(2), \ldots, B(g), \bar{A}(g), B(g), \bar{A}(g) \]

into the tensor product of the handles labelled by

\[ B(1), \bar{A}(1), B(2), \bar{A}(2), \ldots, B(g), \bar{A}(g), B(1), \bar{A}(1), B(2), A(2), \ldots, B(g), \bar{A}(g) \]

Moreover, this manipulation removes exactly the braid \( \Gamma_{4,g} \) in the diagram. Similarly, using repeatedly relation (25), we transform the tensor product of the handles labelled by

\[ M(g+1), M(g+1), M(g+2), \ldots, M(g+n), M(g+n) \]

into the tensor product of the handles labelled by

\[ M(g+1), M(g+2), \ldots, M(g+n), M(g+1), M(g+2), \ldots, M(g+n) \]

and this manipulation removes exactly the braid \( \Gamma_{2,n} \) in the diagram. For the fourth equality, we simply use relation (25) several times to transform the tensor product of the handles labelled by

\[ M(g+1), M(g+1), M(g+2), \ldots, M(g+n), B(1), \bar{A}(1), B(2), A(2), \ldots, B(g), \bar{A}(g) \]

into the tensor product of the handles labelled by

\[ M(g+1), M(g+2), \ldots, M(g+n), B(1), \bar{A}(1), B(2), A(2), \ldots, B(g), \bar{A}(g) \]

and this manipulation removes exactly the braid \( c_{4g,2n} \) in the diagram.
