Abstract

We study generalisations to totally real fields of the methods originating with Wiles and Taylor-Wiles ([32], [31]). In view of the results of Skinner-Wiles [26] on elliptic curves with ordinary reduction, we focus here on the case of supersingular reduction. Combining these, we then obtain some partial results on the modularity problem for semistable elliptic curves, and end by giving some applications of our results, for example proving the modularity of all semistable elliptic curves over \( \mathbb{Q}(\sqrt{2}) \).

1 Introduction

Let \( E \) denote an elliptic curve over a totally real number field \( F \). We say that \( E \) is modular if there is a Hilbert modular form \( f \) over \( F \) of parallel weight 2 (i.e., the corresponding automorphic representation has weight 2 at every infinite place) such that the Galois representation associated to \( E \) via its \( \ell \)-adic Tate module is isomorphic to an \( \ell \)-adic representation associated to \( f \) (see [2] and [28]).

The approach is now standard, and originated in [32] and [31]; one considers the case \( \ell = 3 \), uses the Langlands-Tunnell Theorem to show that the reduction \( \overline{\rho}_{E,3} \) is modular, and then proves that every (suitably constrained) lift to characteristic 0 is modular.

Historically, the easier case has been where \( \overline{\rho}_{E,3} \) is irreducible. In this case, the deformation theory is now well understood, and this was the only case needed by Wiles and Taylor-Wiles ([32], [31]). Over totally real fields, Fujiwara circulated a manuscript [11] some years ago, proving an important generalisation of the method of Taylor-Wiles, and announcing a proof of the modularity of certain elliptic curves over totally real fields. However, there are several hypotheses appearing in his main theorem which we hope partially to eliminate in this work. Subsequently, Skinner and Wiles [26] have proven the modularity in many ‘nearly ordinary’ cases.

In the case where \( \overline{\rho}_{E,3} \) is reducible, Skinner and Wiles [25] have developed new techniques to demonstrate modularity of elliptic curves (and more general Galois representations) over totally real fields, although these results depend on...
certain hypotheses on cyclotomic extensions of $F$. Since the first version of this article was written (2002-3), Kisin has also found stronger results (see [14], [15]).

Reduction to the semistable case

We first remark that the modularity of all elliptic curves over totally real fields may be reduced to proving the modularity of all semistable elliptic curves over totally real fields. The argument is simple; by an explicit version of the semistable reduction theorem (see, for example, [29], Lemma 2.2), an elliptic curve $E$ over a totally real field $F$ attains semistable reduction over a finite soluble totally real Galois extension $F'/F$. (Note that $F'/F$ will be ramified at any prime of $F$ at which $E$ has additive reduction.) The modularity of $E_{/F}$ then follows from the modularity of $E_{/F'}$ using base-change techniques. This argument is well-known to experts, so we omit it here.

For this reason, we restrict attention to semistable curves, and try to prove modularity. In view of some of the applications in mind, we focus in this paper on the easiest case, where the ramification conditions on the field are as strong as possible, but the methods should apply more generally. Because of the results already obtained in the reducible and ordinary cases, we focus on the supersingular case in this paper.

Applications

As we are able to prove the modularity of more elliptic curves than was previously known, we can therefore improve certain results in the literature. Following Wiles’s methods ([32]), we try to find fields for which we can prove modularity of all semistable curves. Wiles ([32], chapter 5) uses a switch between the primes 3 and 5, which depends on the finiteness of $X_0(15)(\mathbb{Q})$; however $X_0(15)(F)$ will generally not be finite. Other restrictions on the field also become apparent in generalising directly his methods. However, we are able to prove modularity of all semistable elliptic curves for the quadratic fields $\mathbb{Q}(\sqrt{2})$ and $\mathbb{Q}(\sqrt{17})$. That we can prove such results for the first of these fields is a piece of good fortune; the first author and Paul Meekin ([12]) have shown that a generalisation of Fermat’s Last Theorem to $\mathbb{Q}(\sqrt{2})$ would follow from such a result. They also show that $\mathbb{Q}(\sqrt{2})$ is the only real quadratic field for which an implication of the form ‘modularity implies Fermat’ can be derived directly.

Notation

The absolute Galois group of a field $F$ is written either as $\text{Gal}(\overline{F}/F)$ or $G_F$. The separable algebraic closure of $F$ is denoted by $\overline{F}$. Given an extension of fields $K \supset F$ and some representation $\rho : G_F \to \text{GL}_2(\ast)$, we denote the restriction of $\rho$ to the absolute Galois group of $K$ by either $\rho|_{G_K}$ or, simply, by $\rho|_K$. If $F$ is a number field, we denote the decomposition and inertia groups at a place $v$ by $D_v$ and $I_v$ respectively.

Throughout, $\ell$ is an odd prime. We denote the $\ell$-adic cyclotomic character by $\epsilon_\ell$, and its reduction, the mod $\ell$ cyclotomic character, by $\overline{\epsilon}_\ell$. We denote by $\omega_2$ the second fundamental character of $\mathbb{Q}_\ell$. Recall that $\omega_2 : I_\ell \to \mathbb{F}_{\ell^2}^\times$ is the
unique character of the inertia subgroup $I_ℓ$ given by the rule

$$τ \rightarrow \frac{τ(ℓ^{1/(ℓ^2-1)})}{ℓ^{1/(ℓ^2-1)}}.$$ 

The notation suppresses the dependence on $ℓ$, and it would be more appropriate to write $ω_{2,ℓ}$ instead; the context should be generally clear. One should recall that the notion of fundamental character is not functorial; the restriction of $ω_2$ to a local inertia group $I_v$ is not the second fundamental character of $F_v$ when the ramification degree of $F_v/\mathbb{Q}_ℓ$ is greater than 1. We remark that there is an injection $\mathbb{F}_ℓ^\times \hookrightarrow \text{GL}_2(\mathbb{F}_ℓ)$; it follows that we can view $ω_2$ as a 2-dimensional representation $Ω_2$ over $\mathbb{F}_ℓ$. This representation is irreducible over $\mathbb{F}_ℓ$, but if we extend scalars to a coefficient field of even degree over $\mathbb{F}_ℓ$, then $Ω_2$ becomes reducible, isomorphic over this quadratic extension to the direct sum of the characters $ω_2$ and $ω_2'$. For an elliptic curve $E$ over a field $F$, we denote by $E[n]$ the kernel of the multiplication by $n$ map $E \times \mathbb{Z}/n\mathbb{Z}$. If $n$ is coprime to the characteristic of $F$, $\rho_{E,n} : G_F \rightarrow \text{Aut} E[n](\mathbb{F}_ℓ) \cong \text{GL}_2(\mathbb{Z}/n\mathbb{Z})$ is the mod $n$ representation. If $ℓ$ is a prime different from the characteristic of $F$, we set $\rho_{E,ℓ} : G_F \rightarrow \text{lim} \text{ Aut} E[ℓ^n](\mathbb{F}_ℓ) \cong \text{GL}_2(\mathbb{Z}_ℓ)$. 

**Summary of results**

Let $F$ be a totally real number field, and let $ℓ$ be an odd prime. Suppose that for all $v | ℓ$, the ramification index of $F_v/\mathbb{Q}_ℓ$ is at most $ℓ-1$. Consider continuous, irreducible representations $\rho : \text{Gal}(\overline{F}/F) \rightarrow \text{GL}_2(\mathbb{Q}_ℓ)$ with determinant the $ℓ$-adic cyclotomic character, and having the same absolutely irreducible residual representation $\overline{ρ}$. We assume that all Artinian quotients of $\rho$ are finite flat at primes above $ℓ$, and we assume further that $\overline{ρ}|_{I_v} \sim Ω_2|_{I_v}$ for every $v | ℓ$

where $Ω_2$ is the second fundamental character of $\mathbb{Q}_ℓ$, as in the notation section above, regarded as a 2-dimensional representation -- as our coefficient field has residue field containing $\mathbb{F}_ℓ$, the representation splits as $ω_2 \oplus ω_2'$. This is the form of the local Galois representations associated to an elliptic curve with good supersingular reduction at $v$, where $F_v$ is unramified over $\mathbb{Q}_ℓ$. (If $F_v$ is not unramified, however, the local Galois representation may take a different form; see section 7 for an example.) The main applications of the results of the paper will be to such elliptic curves.

Our main result is then:

**Theorem 1.1** Let $ρ$ be a representation of the above form. Suppose that $\overline{ρ}$ has a modular lift which is finite flat at primes above $ℓ$. Assume that $\overline{ρ}|_{\text{Gal}(\overline{F}/F(ζ_ℓ))}$ is absolutely irreducible, and furthermore assume that
• if \( \ell = 5 \) and \( \text{Proj} \rho|_{\text{Gal}(\mathbb{Q} / \mathbb{Q} (\zeta_5))} \cong A_5 \) then \([F(\zeta_5) : F] = 4\).

Then \( \rho \) is also modular.

We give two applications of the above. The first relates to Serre’s conjecture for mod 7 representations; we extend the result in [17], and show that:

**Theorem 1.2** Let \( \overline{\rho} : \text{Gal}(\mathbb{Q} / \mathbb{Q}) \to \text{GL}_2(\mathbb{F}_7) \) be an absolutely irreducible, continuous, odd representation. Suppose that the projective image of inertia at 3 has odd order and that the determinant of \( \overline{\rho} \) restricted to the inertia group at 7 has even order. Then \( \overline{\rho} \) is modular.

This theorem has been used by Dieulefait and the second author [8] to give a new criterion for the modularity of rigid Calabi-Yau threefolds. Of course, it is largely subsumed within recent work of Khare and Wintenberger; however, we need no hypothesis at 2.

Our second application relates to the modularity of elliptic curves over totally real fields. For general totally real fields, we prove modularity subject to quite a few restrictions. For the full result, see section 9. A particularly neat corollary is the following.

**Theorem 1.3** Every semistable elliptic curve over \( \mathbb{Q}(\sqrt{2}) \) is modular.

This has implications for the study of certain Diophantine equations, and notably the Fermat equation, over \( \mathbb{Q}(\sqrt{2}) \) (see [12]).

## 2 Local deformations and cohomology groups

Our objective in this section is to give good upper bounds on the size of certain local cohomology groups. We do this for representations of a certain shape (which can be achieved after an unramified base change). But before that, we begin by setting out our notation. Apart from \( \ell \) being the residue characteristic and \( \lambda \) being a uniformizer (instead of \( p \) and \( \pi \)), our choice of notation is meant to be consistent with [3].

Throughout this section, we fix a finite field \( k \) of characteristic \( \ell \geq 3 \). We denote by \( A \) its Witt ring \( W(k) \) and by \( K \) the fraction field of \( A \). We fix a finite totally ramified Galois extension \( K' \) of \( K \) and denote by \( A' \) its ring of integers.

We assume that the absolute ramification index \( e = [K' : K] \) is less than or equal to \( \ell - 1 \). The reason for this is that there is then a good notion of Honda system associated to group schemes. We also fix throughout a uniformizer \( \lambda \) such that \( \lambda^\ell = \ell \) with \( \ell \in A^\times \) (as \( K' \) is a tamely ramified extension). Write \( m \) for the maximal ideal of \( A' \).

We denote by \( \sigma \) the Frobenius automorphism of \( A \), and by \( D_k \) the Dieudonné ring. Recall that \( D_k \) is the \( A \)-algebra generated by \( F \) and \( V \) subject to the usual relations \( FV = \ell = VF, F\alpha = \sigma(\alpha)F, V\alpha = \sigma^{-1}(\alpha)V \) (for \( \alpha \in A \)). If there is no cause for confusion, we will abbreviate \( D_k \) to simply \( D \).

Various tensor products appear in this section. The unspecified \( - \otimes - \) will simply mean \( - \otimes_{\mathbb{Z}_\ell} - \).

We shall be working with finite Honda systems over \( A' \). For the various properties, see Conrad ([3] and [4]).
We now fix a second finite field $F$ of characteristic $\ell$ and a continuous representation
$$\overline{\rho} : G_{K'} \to \text{GL}_2(F).$$
We will shortly impose a further restriction, but for the moment we assume that the representation is finite—that is, there is a finite flat group scheme over $A'$ whose associated Galois module (from the generic fibre) gives precisely our representation $\overline{\rho}$. This allows us to introduce certain cohomology groups $H^1_f(G_{K'}, \text{ad}\overline{\rho})$ and $H^1_f(G_{K'}, \text{ad}^0\overline{\rho})$. We recall the definitions (see [6] for details): elements of $H^1_f(G_{K'}, \text{ad}\overline{\rho})$ are the deformations of $\overline{\rho}$ to $F[\epsilon]/(\epsilon^2)$ which are finite, and $H^1_f(G_{K'}, \text{ad}^0\overline{\rho})$ is the subspace of $H^1_f(G_{K'}, \text{ad}\overline{\rho})$ with determinant (of the deformation) equal to the determinant of $\overline{\rho}$.

We now impose a restriction on the shape of $\overline{\rho}$:

**Assumption 2.1** $\overline{\rho}$ is equivalent to $\Omega_2|G_{K'}$.

Let $M$ be the $D_k \otimes F$-module
$$(k \otimes F)e_1 \oplus (k \otimes F)e_2$$
with $F$ and $V$ actions given by
$$F(e_1) = 0, \quad F(e_2) = e_1;$$
$$V(e_1) = 0, \quad V(e_2) = -e_1.$$  
(To be more precise, these give the action on our basis elements which one then extends Frobenius semi-linearly.) Let $L$ be the subspace $(k \otimes F)e_2$. Then $(L, M)$ is the finite Honda system over $A$ associated to $\Omega_2|G_K$. This follows, after base change (see Section 4 of [3]), from the description of the Honda system over $\mathbb{Z}_\ell$ associated to $\Omega_2$. (This is presumably well known, but a proof is given in the appendix.) We reserve $(L, M)$ for this particular Honda system throughout.

By the results of [3], calculating $H^1_f(G_{K'}, \text{ad}\overline{\rho})$ is the same as calculating extensions of $(L, M)$ by itself in the category of finite Honda systems over $A'$. As a first step to this calculation, we investigate the extensions of $M$ by itself in the category of $D_k \otimes F$ modules.

We begin with a technical lemma which enables us to reduce calculations to one of linear algebra.

**Lemma 2.2** Let $R$ be a ring with finite cardinality. If
$$0 \to R^m \to U \to R^n \to 0$$
is an exact sequence of $R$-modules, then $U$ is free and isomorphic to $R^{n+m}$.

**Proof.** The exact sequence implies that $U$ can be generated by $n+m$ elements. Hence there is a surjective $R$-module homomorphism $R^{n+m} \to U$. As $R$ has finite cardinality, we get $R^{n+m} \cong U$. \qed

**Proposition 2.3** The group of extensions $\text{Ext}^1_{D_k \otimes F}(M, M)$ is (non-canonically) isomorphic as an $F$-vector space to

- $(k \otimes F) \oplus (F_\ell \otimes F)$ if the degree $[k : F_\ell]$ is odd, and
- $(k \otimes F) \oplus (F_\ell^2 \otimes F)$ if the degree $[k : F_\ell]$ is even.
Proof. By Lemma 2.2 we can certainly take any extension class, as an \( A \otimes F \) module, to be

\[
M \oplus M = \left( (k \otimes F)(e_1, 0) \oplus (k \otimes F)(e_2, 0) \right) \oplus \left( (k \otimes F)(0, e_1) \oplus (k \otimes F)(0, e_2) \right).
\]

We need to specify the actions of \( F \) and \( V \). In order to do this, we write down matrices using the above choice of basis and compute (remembering to keep track of Frobenius semi-linearity).

To begin with, we can write

\[
F = \begin{pmatrix} 0 & 1 & f_1 & f_2 \\ 0 & 0 & f_3 & f_4 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{pmatrix} \quad \text{and} \quad V = \begin{pmatrix} 0 & -1 & v_1 & v_2 \\ 0 & 0 & v_3 & v_4 \\ 0 & 0 & 0 & -1 \\ 0 & 0 & 0 & 0 \end{pmatrix}.
\]

Since \( FV = VF = \ell = 0 \), we must have the following equalities:

\[
\begin{align*}
(0 & 1) (\sigma(v_1) & \sigma(v_2)) + (f_1 & f_2) (0 & -1) = 0 \\
(0 & 0) (\sigma(v_3) & \sigma(v_4)) + (f_3 & f_4) (0 & 0) = 0 \\
(0 & -1) (\sigma^{-1}(f_1) & \sigma^{-1}(f_2)) + (v_1 & v_2) (0 & 1) = 0 \\
(0 & 0) (\sigma^{-1}(f_3) & \sigma^{-1}(f_4)) + (v_3 & v_4) (0 & 0) = 0
\end{align*}
\]

Multiplying out, we find that

\[ f_3 = v_3 = 0, \text{ and } f_1 = \sigma(v_4), f_4 = \sigma(v_1). \]

We now reduce the number of variables further by applying appropriate \( k \otimes F \)-linear automorphisms of \( M \oplus M \). Let \( A \) be the endomorphism

\[
\begin{pmatrix} 1 & 0 & a_1 & a_2 \\ 0 & 1 & a_3 & a_4 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.
\]

To calculate \( AFA^{-1} \), we need to calculate

\[
\begin{pmatrix} a_1 & a_2 \\ a_3 & a_4 \end{pmatrix} \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \sigma(a_1) & \sigma(a_2) \\ \sigma(a_3) & \sigma(a_4) \end{pmatrix} + \begin{pmatrix} f_1 & f_2 \\ f_3 & f_4 \end{pmatrix}
\]

which is

\[
\begin{pmatrix} -\sigma(a_3) & a_1 - \sigma(a_4) \\ 0 & a_3 \end{pmatrix} + \begin{pmatrix} f_1 & f_2 \\ f_3 & f_4 \end{pmatrix}.
\]

We can thus assume that \( f_4 = f_2 = 0 \), which implies that \( v_1 = 0 \). Under this assumption, our choice of \( A \) is then restricted to

\[ a_3 = 0 \text{ and } a_1 = \sigma(a_4). \]

To calculate \( AVA^{-1} \), we need to compute

\[
\begin{pmatrix} a_1 & a_2 \\ 0 & a_4 \end{pmatrix} \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix} - \begin{pmatrix} 0 & -1 \\ 0 & 0 \end{pmatrix} \begin{pmatrix} \sigma^{-1}(a_1) & \sigma^{-1}(a_2) \\ \sigma^{-1}(a_3) & \sigma^{-1}(a_4) \end{pmatrix} + \begin{pmatrix} 0 & v_2 \\ 0 & v_4 \end{pmatrix}
\]

6
which is
\[
\begin{pmatrix}
0 & -a_1 + \sigma^{-1}(a_4) \\
0 & 0
\end{pmatrix} + \begin{pmatrix}
0 & v_2 \\
0 & v_4
\end{pmatrix}.
\]
Since we have \(a_1 = \sigma(a_4)\), our choice \(v_2 \in k \otimes F\) can further be restricted to a choice of representative of an element of
\[
k \otimes F/(\sigma^2 - 1)(k \otimes F),
\]
while \(v_4\) can be chosen to be an arbitrary element of \(k \otimes F\). The proposition then follows.

\[\square\]

**Theorem 2.4** The dimension of \(H_1^f(G_{K'}, \text{ad} \rho)\) as an \(F\)-vector space is at most

- \([K' : \mathbb{Q}_\ell] + 2\) if \([k : \mathbb{F}_\ell]\) is even, and
- \([K' : \mathbb{Q}_\ell] + 1\) if \([k : \mathbb{F}_\ell]\) is odd.

**Proof.** As in \([4]\), we have an \(F\)-linear map of vector spaces
\[t : H_1^f(G_{K'}, \text{ad} \rho) \longrightarrow \text{Ext}^1(M, M)\]
In words, the map \(t\) is just ‘take Dieudonné module of the special fibre of the associated finite flat group scheme’. We already have a bound for the Ext-group, thanks to Proposition 2.3. We now start analysing the kernel of the above linear map.

We begin by describing the structure of the \(A'\)-module \(M_{A'}\). We recall the definition (due to Fontaine), and refer to \([3]\) for the explicit description we need (see Definition 2.1 of \([3]\)). As already set out in the beginning of this section, we have a fixed uniformizer \(\lambda\) of \(A'\) satisfying \(\lambda^\ell = \ell^\ell\) with \(\ell \in A^\times\).

We have the standard identification of \(M^{(1)} = (A, \sigma) \otimes_A M\) with \(M\) as an abelian group and twisted \(A\)-action. The Dieudonné module structure then gives us two \(A\)-linear maps
\[
F_0 : M^{(1)} \longrightarrow M \quad \text{and} \quad V_0 : M \longrightarrow M^{(1)}.
\]
(As in \([3]\), we shall not abbreviate these to \(F\) and \(V\).) There are \(A'\)-linear maps
\[
F^M : A' \otimes_A M^{(1)} \longrightarrow A' \otimes_A M \quad \text{and} \quad V^M : m \otimes_A M \longrightarrow \ell^{-1}m \otimes_A M^{(1)}
\]
obtained simply by tensoring with the identity map on \(A'\) and the map \(x \mapsto \ell^{-1}x\) respectively.

The \(A'\)-module \(M_{A'}\) is then the quotient of
\[
(A' \otimes_A M) \oplus (\ell^{-1}m \otimes_A M^{(1)})
\]
by the submodule
\[
\left\{ (\phi_0^M(u) - F^M(w), \phi_1^M(w) - V^M(u)) \mid u \in m \otimes_A M, w \in A' \otimes_A M^{(1)} \right\}
\]
where \(\phi_0^M, \phi_1^M\) are the maps
\[
\phi_0^M : m \otimes_A M \longrightarrow A' \otimes_A M \quad \text{and} \quad \phi_1^M : A' \otimes_A M^{(1)} \longrightarrow \ell^{-1}m \otimes_A M^{(1)}
\]
induced by the inclusions \( m \hookrightarrow A' \) and \( A' \hookrightarrow \ell^{-1}m \).

A basis of \( A' \otimes_A M \) as a free \( k \otimes \mathbb{F} \)-module is given by
\[
\lambda^i \otimes e_j, \ i = 0, \ldots, e - 1, j = 1, 2.
\]
For \( \ell^{-1}m \otimes_A M^{(1)} \), we have the \( k \otimes \mathbb{F} \) basis
\[
\lambda^{-i} \otimes e_j, \ i = 0, 1, \ldots, e - 1, j = 1, 2.
\]

Note that for \( i \geq 1 \), the elements \( (\lambda^i \otimes e_1, 0) \) are trivial in \( M_{A'} \). Indeed, we have
\[
(\lambda^i \otimes e_1, 0) = (\phi_0^M (\lambda^i \otimes e_1) - F^M(0), 0 - V^M(\lambda^i \otimes e_1)).
\]
Furthermore, for \( i \geq 1 \), we have
\[
(0, \lambda^{-i} \otimes e_1) = (0, 0 - V^M(\lambda^{-i} \otimes e_2)) = (-\lambda^{-i} \otimes e_2, 0).
\]

Note also that
\[
(0, 1 \otimes e_1) = (\phi_0^M(0) - F^M(1 \otimes e_1), \phi_1^M(1 \otimes e_1) - V^M(0)), \quad \text{and}
(0, 1 \otimes e_2) = (1 \otimes e_1, 0) + (\phi_0^M(0) - F^M(1 \otimes e_2), \phi_1^M(1 \otimes e_2) - V^M(0)).
\]
Thus any element in \( M_{A'} \) can be expressed as an \( k \otimes \mathbb{F} \)-linear combination of
\[
(1 \otimes e_1, 0), (\lambda^1 \otimes e_2, 0) \quad \text{and} \quad (0, \lambda^{-m} \otimes e_2)
\]
with \( i = 0, 1, \ldots, e - 1 \) and \( m = 1, \ldots, e - 1 \). Since the \( A' \)-length of \( M_{A'} \) is the same as the \( A \)-length of \( M \) times \( e \) (Lemma 2.2 of [3]), we deduce that the set of generators above is in fact a basis.

Obviously, the \( A' \)-submodule of \( M_{A'} \) obtained by taking the \( A' \)-span of \( L \) is precisely \( A' \otimes_A A \otimes \mathbb{F}(e_2, 0) \). Now let \((L', M')\) be the finite Honda system for an element in the kernel of \( t \). Since \( M' = M \oplus M \) as a \( D_k \otimes \mathbb{F} \)-module, we can write \( M'_{A'} = M_{A'} \oplus M_{A'} \). We must therefore have, by length considerations,
\[
L' = (A' \otimes_A A \otimes \mathbb{F})(0, x, 0) + (A' \otimes_A A \otimes \mathbb{F})(0, e_2, 0)
\]
for some \( x \in M_{A'} \). From our description of a basis of \( M_{A'} \), it follows that we can take
\[
x = a(1 \otimes e_1, 0) + y
\]
with \( a \in k \otimes \mathbb{F} \) and \( y \) an element in the \( A \otimes \mathbb{F} \)-span of \( (0, \lambda^{-m} \otimes e_2) \), \( m = 1, \ldots, e - 1 \). By applying a \( D_k \otimes \mathbb{F} \)-linear automorphism of \( M \oplus M \) of the type
\[
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 1
\end{pmatrix},
\]
we can assume that \( a = 0 \). Hence the kernel has dimension, as an \( \mathbb{F} \)-vector space, at most \((e - 1)|k : \mathbb{F}_\ell|\); and this proves the theorem.

**Corollary 2.5** The dimension of \( H^1_J(G_K, \text{ad}^0 \mathcal{P}) \) as an \( \mathbb{F} \)-vector space is at most

- \([K' : \mathbb{Q}_\ell] + 1 \) if \([k : \mathbb{F}_\ell]\) is even, and
- \([K' : \mathbb{Q}_\ell]\) if \([k : \mathbb{F}_\ell]\) is odd.
3 The deformation problem

We now set up the deformation problem we want to study. We begin by fixing a totally real extension $F$ of even degree (over $\mathbb{Q}$), an odd prime $\ell$, a finite field $k$ of characteristic $\ell$, and a continuous homomorphism

$$\overline{\rho}: G_F \rightarrow \text{GL}_2(k)$$

which is absolutely irreducible and odd. We assume that the ramification degree of $F$ at all primes over $\ell$ is less than or equal to $\ell - 1$. Further, we suppose that $\overline{\rho}$ has the following properties:

- The determinant of $\overline{\rho}$ is the mod $\ell$ cyclotomic character.
- $\overline{\rho}$ restricted to the absolute Galois group of $F(\zeta_\ell)$ is absolutely irreducible.
- If $\ell = 5$ and $\text{Proj} \overline{\rho}|_{\text{Gal}(F/F(\zeta_\ell))}$ then $[F(\zeta_\ell):F] = 4$.
- Let $x$ be a prime of $F$ above $\ell$ and let $I_x$ the inertia group of $F_x$. Then

$$\overline{\rho}|_{I_x} \sim \Omega_2|_{I_x}$$

where $\Omega_2$ is the second fundamental character.

We assume that the characteristic polynomial of $\overline{\rho}(\sigma)$ is split over $k$ for any $\sigma \in G_F$. We fix a finite extension $K$ of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$, maximal ideal $(\lambda)$ and residue field $k$.

Let $\mathcal{C}_\mathcal{O}$ be the category of complete, local, Noetherian $\mathcal{O}$-algebras with residue field $k$. Given $(A, m_A) \in \mathcal{C}_\mathcal{O}$, we call a continuous homomorphism

$$\rho_A : G_F \rightarrow \text{GL}_2(A)$$

a finite flat deformation of $\overline{\rho}$ if

- $\rho_A$ is odd and unramified outside finitely many primes,
- $\rho_A \pmod{m_A} = \overline{\rho}$,
- $\rho_A$ is finite flat at primes $v|\ell$ (i.e., the restriction of $\rho_A$ to $G_{F_v}$, for $v|\ell$, has the property that for all $n \geq 1$, the $F_v$-group scheme associated to the $G_{F_v}$-module $\rho_A \pmod{m_A^n}$ is the generic fibre of a finite flat group scheme over $\mathcal{O}_{F_v}$), and
- $\rho_A$ has determinant the $\ell$-adic cyclotomic character.

Two such deformations are said to be strictly equivalent if one can be conjugated to the other by a matrix which reduces to the identity modulo the maximal ideal $m_A$.

Now let $\Sigma$ be a finite set of (finite) primes of $F$ not containing any places over $\ell$ (and it could be empty). We say a finite flat deformation is of type $\Sigma$ if the representation is unramified outside primes in $\Sigma$ and outside the set of primes where $\overline{\rho}$ is ramified. There is then a universal finite flat deformation of $\overline{\rho}$ of type $\Sigma$ which we shall denote by $(R_{\Sigma}, \rho_{\Sigma})$.

Given a finite flat deformation $\rho : G_F \rightarrow \text{GL}_2(\mathcal{O}/\lambda^n)$ of type $\Sigma$, one defines the Galois cohomology group $H^1_{\Sigma}(G_F, \text{ad}^0 \rho)$ to be the deformations of $\rho$ to
(\mathcal{O}/\mathcal{L}^n)[\ell]/\ell^2 \) which are of type \( \Sigma \). Recall that \( \text{ad}^0 \rho \) can be identified with the group of \( 2 \times 2 \) trace zero matrices over \( \mathcal{O}/\mathcal{L}^n \) with \( G_F \) action via conjugation (by \( \rho \)). The cohomology group \( H_{\Sigma}^1(G_F, \text{ad}^0 \rho) \) is then precisely \( H_{\Sigma}^1(G_F, \text{ad}^0 \rho) \) where the local conditions \( \Sigma = \{ L_x \} \) are given by:

- \( L_x = H^1(G_{F_x}/I_x, \text{ad}^0 \rho) \) if \( x \not| \ell \), \( x \not\in \Sigma \) and \( \mathfrak{p} \) is unramified at \( x \),
- \( L_x = H^1(G_{F_x}, \text{ad}^0 \rho) \) if \( x \not| \ell \), and either \( x \in \Sigma \) or \( \mathfrak{p} \) is ramified at \( x \),
- \( L_x = H^1(G_{F_x}, \text{ad}^0 \rho) \) if \( x | \ell \).

The universal deformation ring \( R_{\Sigma} \) can be topologically generated as an \( \mathcal{O} \)-algebra by \( \dim \mathfrak{p} H_{\Sigma}^1(G_F, \text{ad}^\mathfrak{p}(1)) \) elements. If \( \pi : R_{\Sigma} \to \mathcal{O} \) is an \( \mathcal{O} \)-algebra homomorphism with corresponding representation \( \rho \), we have a canonical isomorphism

\[
\text{Hom} (\ker \pi/(\ker \pi)^2, K/\mathcal{O}) \cong H_{\Sigma}^1(G_F, \text{ad}^0 \rho \otimes K/\mathcal{O}).
\]

The pairing \( \text{ad}^0 \mathfrak{p} \times \text{ad}^0 \mathfrak{p} \to k \) obtained by taking the trace is perfect. Using this pairing, one defines \( H_{\Sigma}^1(G_F, \text{ad}^\mathfrak{p}(1)) \) to be given by local conditions \( \{ L_x^\perp \} \) where \( L_x^\perp \) is the orthogonal complement to \( L_x \) with respect to the perfect pairing

\[
H^1(G_{F_x}, \text{ad}^\mathfrak{p}) \times H^1(G_{F_x}, \text{ad}^\mathfrak{p}(1)) \to H^2(G_{F_x}, k(1)) \simeq k.
\]

From now onwards, we assume the following:

**Assumption 3.1** For each prime \( x \) of \( F \) dividing \( \ell \), the Honda system associated to \( \mathfrak{p}_{F_x} \) has the particular form specified in Assumption 2.1.

Now we make some calculations of these cohomology groups, using similar arguments to those of Wiles.

**Theorem 3.2** As an \( \mathcal{O} \)-algebra,

\[
\dim_k H_{\Sigma}^1(G_F, \text{ad}^\mathfrak{p}(1)) + \sum_{x \in \Sigma} \dim_k H^0(G_{F_x}, \text{ad}^\mathfrak{p}(1))
\]

elements are sufficient to generate the universal deformation ring \( R_{\Sigma} \) topologically.

**Proof.** This is almost exactly the same as the proof of Corollary 2.43 in [6]. Using Theorem 2.19 of [6] (a full proof is given in [18], p.440), one finds that \( \dim_k H_{\Sigma}^1(G_F, \text{ad}^\mathfrak{p}) \) is the sum of terms:

- \( \dim_k H_{\Sigma}^1(G_F, \text{ad}^\mathfrak{p}(1)) \);
- \( \sum_{x | \ell} \dim_k H^1(G_{F_x}) - \sum_{x | \ell} \dim_k H^0(G_{F_x}) - \sum_{x | \ell} \dim_k H_{\Sigma}^0(G_{F_x}) \), where \( H^*_x(G_{F_x}) \) means the cohomology group \( H^*_x(G_{F_x}, \text{ad}^\mathfrak{p}) \). This term is less than or equal to 0 by Corollary 2.5;
- \( \dim_k H^1(G_{F_x}, \text{ad}^\mathfrak{p}) - \dim_k H^0(G_{F_x}, \text{ad}^\mathfrak{p}) \), which equals \( \dim_k H^0(G_{F_x}, \text{ad}^\mathfrak{p}(1)) \), for each \( x \in \Sigma \).

\[ \square \]
Theorem 2.49 of [6] still holds in our present setting; the proof, with trivial modifications, remains valid. The result being of significant importance, we give a brief sketch of the proof.

**Theorem 3.3** Let $r = \dim_k H^1_\emptyset(G_F, \mathrm{ad}^0 \mathfrak{p}(1))$. For every positive integer $n$, we can find a finite set primes $\Sigma_n$ such that the following hold:

- Every prime in $\Sigma_n$ has norm congruent to 1 modulo $\ell^n$;
- The sets $\Sigma_n$ all have size equal to $r$;
- If $x \in \Sigma_n$, then $\mathfrak{p}$ is unramified at $x$ and the Frobenius (at $x$) has distinct eigenvalues;
- The universal deformation ring $R_{\Sigma_n}$ can be topologically generated as an $O$-algebra by $r$ elements.

**Proof.** As in the proof of Theorem 2.49 of [6], one reduces the result to showing that for $\psi \in H^1_\emptyset(G_F, \mathrm{ad}^0 \mathfrak{p}(1)) - \{0\}$, we can find a $\sigma \in G_F$ such that

- $\sigma$ acts trivially on $F(\zeta_n)$,
- $\mathrm{ad}^0 \mathfrak{p}(\sigma)$ has an eigenvalue not equal to 1, and
- $\psi(\sigma) \notin (\sigma - 1)\mathrm{ad}^0 \mathfrak{p}(1)$.

(We remark that Theorem 3.2 is crucial in getting the right number of generators from this reduction.)

Let $F_n$ be the minimal extension of $F(\zeta_n)$ on which $\mathrm{ad}^0 \mathfrak{p}$ acts trivially. The degree of the extension $F_1/F_0$ is at most $\ell - 1$; the degree $[F_n : F_1]$ is of $\ell$-power order. It follows that

$$H^1(\mathrm{Gal}(F_n/F_0), \mathrm{ad}^0 \mathfrak{p}(1))^{G_F} \cong \mathrm{Hom}(\mathrm{Gal}(F_n/F_1), \mathrm{ad}^0 \mathfrak{p}(1)^{G_F})$$

is trivial (since $\mathfrak{p}$ restricted to the absolute Galois group of $F(\zeta)$ is absolutely irreducible).

Now consider $H^1(\mathrm{Gal}(F_0/F), \mathrm{ad}^0 \mathfrak{p}(1))^{G_{F_0}}$. If this is non-trivial, the order of $\mathrm{Gal}(F_0/F)$ must be divisible by $\ell$ and $\mathrm{Gal}(F_0/F)$ must have $\mathrm{Gal}(F(\zeta)/F)$ as a quotient. Note that $\mathrm{Gal}(F_0/F)$ is isomorphic to the projective image of $\mathfrak{p}$, and so from the list in Theorem 2.47 of [6] we see that the case $\ell = 5$ and $\mathrm{Proj} \mathfrak{p}|_{\mathrm{Gal}(F/F(\zeta))}$ cannot occur. In the other cases the projective image of $\mathfrak{p}$ is a semi-direct extension of $\mathrm{PSL}_2(\mathbb{F}_{\ell^n})$ by a group of order prime to $\ell$, and so $H^1(\mathrm{Gal}(F_0/F), \mathrm{ad}^0 \mathfrak{p}(1))$ again vanishes on applying Lemma 2.48 of [6].

A straightforward application of the inflation-restriction sequence then implies that the group $H^1(\mathrm{Gal}(F_n/F), \mathrm{ad}^0 \mathfrak{p}(1))$ is trivial, and it follows that $\psi(G_{F_n})$ is non-trivial.

Now $\mathfrak{p}$ restricted to $G_{F(\zeta)}$ is still absolutely irreducible. Thus the order of $\mathrm{Gal}(F_n/F(\zeta))$ is not a power of $\ell$. The group $\mathrm{Gal}(F_n/F(\zeta))$ also acts (non-trivially) on $\{0\} \neq \psi(G_{F_n}) \subset \mathrm{ad}^0 \mathfrak{p}$. Therefore we can find a non-trivial element $g \in \mathrm{Gal}(F_n/F(\zeta))$ of order prime to $\ell$ and fixing a non-zero element of $\psi(G_{F_n})$. Let $g \in G_{F(\zeta)}$ be a lift of $g$. As $\psi(G_{F_n}) \not\subset (g - 1)\mathrm{ad}^0 \mathfrak{p}(1)$, we can find an $h \in G_{F_n}$ such that

$$\psi(h\tilde{g}) = \psi(h) + \psi(\tilde{g}) \notin (\tilde{g} - 1)\mathrm{ad}^0 \mathfrak{p}(1).$$
Finally, take \( \sigma = h\tilde{g} \). Then \( \sigma \) acts trivially on \( F(\zeta_{\ell^m}) \), and \((\sigma - 1)\text{ad}^n\bar{\varphi}(1) = \tilde{g} - 1\text{ad}^n\bar{\varphi}(1) \not\in \psi(\sigma) \). Since the order of \( \sigma \) is prime to \( \ell \) (and is not 1), it follows that \( \text{ad}^n\bar{\varphi}(\sigma) \) has an eigenvalue not equal to 1. \( \square \)

4 Hecke algebras and \( \ell \)-adic modular forms

We fix a totally real field \( F \) of even degree and an odd rational prime \( \ell \). We write \( D \) for the division algebra with centre \( F \) and ramified exactly at the set of infinite places of \( F \). Write \( Z \) for the algebraic group defined by \( Z(R) = (D \otimes_F R)^\times \) if \( R \) is an \( F \)-algebra. We also fix the following:

- A maximal order \( \mathcal{O}_D \), and isomorphisms \( \mathcal{O}_{D,x} \cong M_2(\mathcal{O}_{F,x}) \) for all finite places \( x \) of \( F \).
- A uniformiser \( \varpi_x \) of \( \mathcal{O}_{F,x} \) for each finite place \( x \).

We write \( A \) for a topological \( \mathbb{Z}/\ell \)-algebra which is one of the following: a finite extension of \( \mathbb{Q}/\ell \), the ring of integers in such an extension, or a quotient of such a ring of integers.

**Definition 4.1** For a compact open subgroup \( U \subset (D \otimes \mathbb{Q} \mathbb{A}^\infty)^\times \) and a topological ring \( A \) as above, we define \( S_A(U) \) to be the space of continuous functions

\[
f : (D \otimes \mathbb{Q} \mathbb{A}^\infty)^\times / U.Z(\mathbb{A}\mathbb{P}^\infty) \longrightarrow A.
\]

We define \( S_A \) to be the direct limit of \( S_A(U) \) as \( U \) varies over open compact subsets of \( (D \otimes \mathbb{Q} \mathbb{A}^\infty)^\times \).

For a compact open \( U \), the finite double coset decomposition

\[
(D \otimes \mathbb{Q} \mathbb{A}^\infty)^\times = \bigsqcup_i D^\times U_i.Z(\mathbb{A}\mathbb{P}^\infty)
\]

shows that

\[
S_A(U) \longrightarrow \bigoplus_i A
\]

\[
f \longrightarrow (f(U_i))_i
\]

is an isomorphism. In particular, for any \( A \)-algebra \( B \), we have

\[
S_A(U) \otimes_A B \cong S_B(U).
\]

We denote by \([t_i]\) the function in \( S_A(U) \) which is 1 on \( D^\times U_i.Z(\mathbb{A}\mathbb{P}^\infty) \) and 0 elsewhere.

**Definition 4.2** For an ideal \( n \) of \( \mathcal{O}_F \) and quotients \( H_x \) of \( (\mathcal{O}_{F,x}/n_x)^\times \), we set \( \mathcal{H} = \prod_x H_x \). We define \( U_H(n) \) to be the compact open subgroup \( \prod_x U_H(n)_x \subset (D \otimes \mathbb{Q} \mathbb{A}^\infty)^\times \) where

\[
U_H(n)_x = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \text{GL}_2(\mathcal{O}_{F,x}) \cong \mathcal{O}_{D,x}^\times \middle| c \in n_x, \ ad^{-1} = 1 \text{ in } H_x \right\}.
\]
Now let \( n \) and \( H_x \) be as in the above definition. We recall the definitions of the various Hecke operators on \( S_A(U_H(n)) \):

- If \( x \) does not divide \( \ell n \), we denote the Hecke operators
  \[
  \left[ U_H(n) \begin{pmatrix} \omega_x & 0 \\ 0 & 1 \end{pmatrix} U_H(n) \right] \quad \text{and} \quad \left[ U_H(n) \begin{pmatrix} \omega_x & 0 \\ 0 & \omega_x \end{pmatrix} U_H(n) \right]
  \]
  by \( T_x \) and \( S_x \) respectively.

- If \( x \) divides \( n \), we set
  \[
  \langle h \rangle = \left[ U_H(n) \begin{pmatrix} \hat{h} & 0 \\ 0 & 1 \end{pmatrix} U_H(n) \right]
  \]
  for \( h \in H_x \) and \( \hat{h} \) a choice of lift of \( h \) to \( \mathcal{O}_F^\times \).

- If \( x \) divides \( n \), the Hecke operators
  \[
  \left[ U_H(n) \begin{pmatrix} \omega_x & 0 \\ 0 & 1 \end{pmatrix} U_H(n) \right] \quad \text{and} \quad \left[ U_H(n) \begin{pmatrix} 1 & 0 \\ 0 & \omega_x \end{pmatrix} U_H(n) \right]
  \]
  are denoted by \( U_{\omega_x} \) and \( V_{\omega_x} \) respectively. We also denote by \( S_x \) the Hecke operator
  \[
  \left[ U_H(n) \begin{pmatrix} \omega_x & 0 \\ 0 & \omega_x \end{pmatrix} U_H(n) \right].
  \]

**Definition 4.3** Let \( n \), \( H_x \), and \( A \) be as in the preceding paragraphs. We define the Hecke algebra \( \mathbb{T}_A(U_H(n)) \) to be the \( A \)-subalgebra of \( \text{End}_A(S_A(U_H(n))) \) generated by \( T_x \) (for \( x \) not dividing \( \ell n \)) and \( U_{\omega_x} \) (for \( x \) dividing \( n \) but not dividing \( \ell \)).

A maximal ideal \( m \) of \( \mathbb{T}_A(U_H(n)) \) is said to be Eisenstein if it contains \( T_x - 2 \) and \( S_x - 1 \) for all but finitely many primes with \( n \times (\text{mod} \ \ell) = 1 \).

The Hecke algebra \( \mathbb{T}_A(U_H(n)) \) is always commutative. Also, \( \mathbb{T}_{\mathcal{O}_F}(U_H(n)) \) is semi-local and \( \ell \)-adically complete, and we have the identification
\[
\mathbb{T}_{\mathcal{O}_F}(U_H(n)) \cong \prod_m \mathbb{T}_{\mathcal{O}_F}(U_H(n))_m
\]
where the product is over all maximal ideals \( m \).

If either \( \ell \) is invertible in \( A \), or if \( \mathbb{Q} (\zeta + \zeta^{-1}) \nsubseteq F \) where \( \zeta \) is a primitive \( \ell \)th root of unity, we have a perfect pairing on \( S_A(U_H(n)) \) defined by
\[
(f_1, f_2)_{U_H(n)} = \sum_i f_1(t_i)f_2(t_i) \left( \frac{\# U_H(n).\mathbb{Z}(\mathbb{A}_F) \cap t_i^{-1}D^\times t_i}{F^\times} \right)^{-1}
\]
where
\[
(D \otimes_{\mathbb{Q}} \mathbb{A}_{\infty})^\times = \prod D^\times t_i U_H(n).\mathbb{Z}(\mathbb{A}_F).
\]
We call this the standard pairing. The Hecke operators are not necessarily self-adjoint with respect to this pairing; the general behaviour of operators is given by
\[
([U_{H'}(n')g U_H(n)] f_1, f_2)_{U_{H'}(n')} = (f_1, [U_H(n)g^{-1}U_{H'}(n')] f_2)_{U_H(n)}.
\]
Now fix a finite set of primes $\Sigma$, none lying above $\ell$, and let $n_\Sigma = \prod_{x \in \Sigma} x^2$. Let $K$ be a finite extension of $\mathbb{Q}_\ell$ which contains all embeddings $F \hookrightarrow \mathbb{Q}_\ell$, and let $\mathcal{O}$ be its ring of integers. We fix a decomposition
\[(D \otimes_{\mathbb{Q}} \mathbb{A}_F)\times = \coprod D^x g_i U_1(n_\Sigma) Z(A_F) \times \prod D^x h_i U_1(n_\Sigma) Z(A_F)\]
where the $g_i$'s and $h_i$'s are such that
\[\ell \div \# U_1(n_\Sigma) Z(A_F) \cap g_i^{-1} D^x g_i \quad \text{and} \quad \ell \div \# U_1(n_\Sigma) Z(A_F) \cap h_i^{-1} D^x h_i.
\]
We denote by $S_{\mathcal{O}}(U_1(n_\Sigma))^*$ the $\mathcal{O}$-submodule of $S_{\mathcal{O}}(U_1(n_\Sigma))$ generated by the $[g_i]$ and $\ell [h_i]$.

**Lemma 4.4** Keep the notation of the preceding paragraph, and suppose that the ramification index at all primes over $\ell$ of $F$ is at most $\ell - 1$. Then $\ell$ exactly divides the order of $(U_1(n_\Sigma) Z(A_F) \cap h_i^{-1} D^x h_i)/F^\times$.

**Proof.** One easily reduces the statement to showing that finite subgroups of $D^\times$ having $\ell$-power order must have order exactly $1$ or $\ell$ (use the two exact sequences in the proof of Lemma 1.1 of [30]). Further, there can be a non-trivial finite subgroup of $\ell$-power order if and only if $\zeta + \zeta^{-1}$ is in $F$. Since any group of order $\ell^2$ is abelian, the only possible non-trivial finite subgroup has to have order exactly $\ell$. \hfill \Box

**Lemma 4.5** With the notation as above, let $f \in S_{\mathcal{O}}(U_1(n_\Sigma))$. Then $T_\chi(f) \in S_{\mathcal{O}}(U_1(n_\Sigma))^*$ for any prime $x \notin \Sigma$ with $N_x \equiv -1 \pmod{\ell}$.

**Proof.** Let $U^{(0)}$ be the subgroup of $U_1(n_\Sigma)$ consisting of elements whose $x$th component is congruent to $\begin{pmatrix} \ast & 0 \\ \ast & \ast \end{pmatrix}$ (mod $\wp_x$). Let $\zeta \in h^{-1} D^x h \cap U_1(n_\Sigma) Z(A_F)$ have order exactly $\ell$ in the quotient $(h^{-1} D^x h \cap U_1(n_\Sigma) Z(A_F))/F^\times$. We need to compute $T_\chi(f)(h)$ and check that it is a multiple of $\ell$. Starting with a double coset decomposition given by $\prod_{i=1}^{\ell - 1} \zeta^i \ast U^{(0)}$ and using the fact that $\zeta \notin U^{(0)}$, we get a disjoint decomposition
\[U_1(n_\Sigma) = \coprod_{i=1}^{\ell} \prod_{j=1}^{(N_\Sigma + 1)/\ell} \zeta^i u_j U^{(0)}.
\]
This shows that, by index considerations,
\[U_1(n_\Sigma) \begin{pmatrix} \wp_x & 0 \\ 0 & 1 \end{pmatrix} U_1(n_\Sigma) = \coprod_{i=1}^{\ell} \prod_{j=1}^{(N_\Sigma + 1)/\ell} \zeta^i u_j \begin{pmatrix} \wp_x & 0 \\ 0 & 1 \end{pmatrix} U_1(n_\Sigma).
\]
Since $h \zeta^i = d_i h$ for some $d_i \in D^\times$, we have
\[
T_\chi(f)(h) = \sum_{i=1}^{\ell} \sum_{j=1}^{(N_\Sigma + 1)/\ell} f \left( h \zeta^i u_j \begin{pmatrix} \wp_x & 0 \\ 0 & 1 \end{pmatrix} \right) \\
= \sum_{i=1}^{\ell} \sum_{j=1}^{(N_\Sigma + 1)/\ell} f \left( h u_j \begin{pmatrix} \wp_x & 0 \\ 0 & 1 \end{pmatrix} \right) \\
= \ell \sum_{j=1}^{(N_\Sigma + 1)/\ell} f \left( h u_j \begin{pmatrix} \wp_x & 0 \\ 0 & 1 \end{pmatrix} \right).
\]
The lemma follows.

Now we discuss various properties of the modular forms and Hecke operators.

**Theorem 4.6** Keeping the assumptions of the two preceding lemmas, we have the following:

1. The \( \mathcal{O} \)-module \( S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma))^* \) is invariant under the action of Hecke operators.

2. The pairing on \( S_K(U_1(\mathfrak{n}_\Sigma)) \) induces a perfect pairing

\[
S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma)) \times S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma))^* \longrightarrow \mathcal{O}.
\]

3. Let \( \mathfrak{m} \) be a non-Eisenstein maximal ideal of the Hecke algebra \( T_\mathcal{O}(U_0) \). Then \( S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma))_\mathfrak{m} = S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma))^{\mathfrak{m}}_\mathfrak{m} \). As a consequence, the pairing on \( S_K(U_1(\mathfrak{n}_\Sigma)) \) induces a perfect pairing on \( S_\mathcal{O}(U_1(\mathfrak{n}_\Sigma))^{\mathfrak{m}}_\mathfrak{m} \).

**Proof.** The first part is easily checked using the given pairing on \( S_K(U_1(\mathfrak{n}_\Sigma)) \). The second part follows from Lemma 4.4. The third part is a direct consequence of Lemma 4.5. □

5 **Deformations in the minimal case**

In this section, we show that the universal deformation ring in the minimal case is isomorphic to a Hecke algebra, and we show that these are complete intersection rings of relative dimension zero over \( \mathbb{Z}_p \).

Recall that we are given a continuous representation

\[
\overline{\rho} : G_F \longrightarrow \text{GL}_2(k)
\]
satisfying the various properties listed in the beginning of section 3 and also satisfying Assumption 5.1. In this and the next section, we shall assume the following additional modularity condition.

**Assumption 5.1** Let \( U_0 \) denote \( U_{\{1\}}(\mathfrak{n}_\emptyset) \). Then we assume that there is a continuous homomorphism \( \phi : T_\mathcal{O}(U_0) \rightarrow k \) with non-Eisenstein kernel which gives our representation \( \overline{\rho} \). We write \( \mathfrak{m}_\emptyset \) for the kernel.

Our aim is to show that the natural map \( R_\emptyset \rightarrow T_\mathcal{O}(U_0)_{\mathfrak{m}_\emptyset} \) is an isomorphism of complete intersection rings.

Fix a finite set of primes \( \Sigma \) of \( F \) not dividing \( \ell \) such that for every \( x \in \Sigma \), we have

- \( N_x \equiv 1 \pmod{\ell} \),

- \( \overline{\rho} \) is unramified at \( x \) and has distinct eigenvalues \( \alpha_x \neq \beta_x \).

We denote the maximal \( \ell \)-power quotient of \( (\mathcal{O}_F/x)^\times \), for \( x \in \Sigma \), by \( \Delta_x \) and set \( \Delta_\Sigma = \prod \Delta_x \). We define the following objects (all products are over \( x \in \Sigma \)):

1. an ideal \( \mathfrak{n}_\Sigma = \prod x^2 \).
2. compact open subgroups $U_{0,\Sigma} = U_{(1)}(n_\Sigma)$ and $U_{1,\Sigma} = U_{\Delta}(n_\Sigma)$.

3. an ideal $m_\Sigma$ of either $T(U_{0,\Sigma})$ or $T(U_{1,\Sigma})$ generated by $\ell$ and
   \begin{itemize}
   \item $T_x - \text{tr}(\text{Frob}_x)$ for $x \not| \ell n_\Sigma$, and
   \item $U_{mx} - \alpha_x$ for $x \in \Sigma$.
   \end{itemize}

Note that Lemma 2.1 and Lemma 2.2 of [30] remain true in the present situation (and we will write them down again in a moment). We also have the fact that $S_0(U_{1,\Sigma})$ is an $O[\Delta]\Sigma$-module via $h \mapsto \langle h \rangle$. But slight care is required for the critical Lemma 2.3 and Corollary 2.4 of [30]: it is no longer obvious that $S_0(U_{1,\Sigma})m_\Sigma$ is free over $O[\Delta]\Sigma$. Nonetheless, we can still get the ‘patching modules’ technique of [7] to work.

We first present a trivial reformulation of Theorem 2.1 of [7].

**Theorem 5.2** Fix a positive integer $r$, a finite field $k$; set $A = k[[S_1,\ldots,S_r]]$ and $B = k[[X_1,\ldots,X_r]]$. We denote the maximal ideal of $A$ by $n$. We are given: a $k$-algebra $R$, a non-zero $R$-module $H$ which is finite dimensional over $k$.

For each positive integer $n$, we suppose that we have $k$-algebra homomorphisms $\phi_n : A \rightarrow B$ and $\psi_n : B \rightarrow R$, a $B$-module $H_n$ and a $B$-linear homomorphism $\pi_n : H_n \rightarrow H$ such that:

\begin{itemize}
   \item $\psi_n$ is surjective and $\psi_n \phi_n = 0$,
   \item $\pi_n$ induces an isomorphism between $H_n/nH_n$ and $H$, and
   \item there is an unbounded sequence of positive integers $(a_n)_{n \geq 1}$ such that $H_n/n^{a_n}H_n$ is free over $A/n^{a_n}$.
\end{itemize}

Then $R$ is a complete intersection, and $H$ is free over $R$.

We now begin analyzing and comparing the $O[\Delta]\Sigma$-module structures of $S_0(U_{0,\Sigma})$ and $S_0(U_{1,\Sigma})$. Denote the augmentation ideal of $O[\Delta]\Sigma$ by $I_{\Delta}\Sigma$. Obviously, functions in $S_0(U_{0,\Sigma})$ are precisely the elements of $S_0(U_{1,\Sigma})$ which are invariant under the action of $\Delta\Sigma$; there is a ‘norm’ map

$$\sum_{h \in \Delta\Sigma} \langle h \rangle : S_0(U_{1,\Sigma}) \rightarrow S_0(U_{0,\Sigma})$$

where the subscript denotes coinvariants.

**Proposition 5.3** The norm map

$$\sum_{h \in \Delta\Sigma} \langle h \rangle : S_0(U_{1,\Sigma}) \rightarrow S_0(U_{0,\Sigma})$$

has kernel $I_{\Delta\Sigma}S_0(U_{1,\Sigma})$ and surjects onto $S_0(U_{0,\Sigma})^*$.

The $T(U_{1,\Sigma})$-module

$$\left( \sum_{h \in \Delta\Sigma[\ell]} h \right) S_0(U_{1,\Sigma})$$

is free over $O[\Delta\Sigma]/\Delta\Sigma[\ell]$; and the norm map factorizes, in an obvious way, as the composite of

$$\sum_{h \in \Delta\Sigma[\ell]} \langle h \rangle \quad \text{and} \quad \sum_{h \in \Delta\Sigma/\Delta\Sigma[\ell]} \langle h \rangle.$$

16
Proof. We have a decomposition
\[(D \otimes \mathcal{O} \mathbb{A}^\infty)^\times = \prod D^x t_i U_{0,\Sigma} Z(\mathbb{A}_F^\infty).\]

For \(h \in \Delta_{\Sigma}\), we have a lift \(\tilde{h} \in (\mathbb{A}_F^\infty)^\times\) which gives the coset decomposition
\[U_{0,\Sigma} = \prod_{h \in \Delta_{\Sigma}} \begin{pmatrix} \tilde{h} & 0 \\ 0 & 1 \end{pmatrix} U_{1,\Sigma}.\]

There is an obvious transitive action of \(\Delta_{\Sigma}\) on this coset decomposition.

For each \(t_i\), we define
\[\text{Stab}_i = \left\{ h \in \Delta_{\Sigma} \mid D^x t_i U_{1,\Sigma} Z(\mathbb{A}_F^\infty) = D^x t_i \begin{pmatrix} \tilde{h} & 0 \\ 0 & 1 \end{pmatrix} U_{1,\Sigma} Z(\mathbb{A}_F^\infty) \right\}.\]

Obviously, the definition is independent of the representatives \(t_i\) and depends only on the coset decomposition. We get the double coset decomposition
\[(D \otimes \mathcal{O} \mathbb{A}^\infty)^\times = \prod_i \prod_{h \in \Delta_{\Sigma}/\text{Stab}_i} D^x t_i \begin{pmatrix} \tilde{h} & 0 \\ 0 & 1 \end{pmatrix} U_{1,\Sigma} Z(\mathbb{A}_F^\infty).\]

In particular, we see that the set
\[\bigcup_i \{ (h)[t_i] \mid h \in \Delta_{\Sigma}/\text{Stab}_i \}\]

is a basis for the free \(\mathcal{O}\)-module \(S_\mathcal{O}(U_{1,\Sigma})\).

It is now clear that the image of the map
\[\sum_{h \in \Delta_{\Sigma}} \langle h \rangle : S_\mathcal{O}(U_{1,\Sigma}) \to S_\mathcal{O}(U_{0,\Sigma})\]

is free over \(\mathcal{O}\) with basis \(\{|\text{Stab}_i|[t_i]\}_i\). The fact that the kernel is the image of the augmentation ideal is obvious once we show that it is enough to consider elements in the kernel having the form
\[x = \sum_{h \in \Delta_{\Sigma}/\text{Stab}_i} a_h \langle h \rangle[t_i] \quad \text{with} \quad a_h \in \mathcal{O} \quad \text{and} \quad \sum_{h \in \Delta_{\Sigma}/\text{Stab}_i} a_h = 0.\]

It suffices to consider such \(x\) because we can write \(x = \sum x_i\), where \(x_i\) lies in the kernel and has the form \(|\text{Stab}_i|[\sum a_i][t_i]\).

We now show that the image of the norm map is \(S_\mathcal{O}(U_{0,\Sigma})^\times\) by proving that the order of \(\text{Stab}_i\) is equal to the power of \(\ell\) that divides the order of \((t_i^{-1} D^x t_i \cap U_{0,\Sigma} Z(\mathbb{A}_F^\infty)) / F^x\).

We claim that the order of \((t_i^{-1} D^x t_i \cap U_{1,\Sigma} Z(\mathbb{A}_F^\infty)) / F^x\) is not divisible by \(\ell\). Indeed, let \(\alpha \in t_i^{-1} D^x t_i \cap U_{1,\Sigma} Z(\mathbb{A}_F^\infty)\) be such that \(\alpha^\ell \in F^x\). Fix a place \(x \in \Sigma\). We can write the \(x\)-th component of \(\alpha \in U_{1,\Sigma} Z(\mathbb{A}_F^\infty)\) as \(u_x z_x\) where \(z_x \in K_x\) and \(u_x \in GL_2(\mathcal{O}_x)\) satisfies
\[u_x \equiv \begin{pmatrix} h & \ast \\ 0 & 1 \end{pmatrix} \quad (\text{mod} \ \omega_x)\]

17
with $h$ having order prime to $\ell$. Raising $u_x$ to the $\ell$-th power, one deduces that $u_x$ reduces to the identity mod $\omega_x$, and hence that $u_x$ is trivial. This then implies that $\alpha \in F^\times$.

Let $m$ be the prime to $\ell$ part of the order of $(t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)) / F^\times$. We define a map $\theta : \text{Stab}_1 \rightarrow (t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)) / F^\times$ as follows: If $h \in \text{Stab}_1$, we must have $t_i^{-1}dh_i = uh_i = x$ (say) for some $d \in D^\times$, $u_1 \in U_{1,\Sigma}$ and $a \in (\mathbb{A}_F^\infty)^\times$. Thus $x \in t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)$, and we set $\theta(h) = x^m \mod F^\times$. By the claim established in the previous paragraph, it follows that $\theta$ is a well-defined injective homomorphism from $\text{Stab}_1$ to the $\ell$-primary part of $(t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)) / F^\times$. Since by Lemma 4.21 the order of the $\ell$-primary part of $(t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)) / F^\times$ is exactly $\ell$ or 1, it is then simple to verify that $\theta$ is an isomorphism between $\text{Stab}_1$ and the $\ell$-primary part of $(t_i^{-1}D^\times t_i \cap U_{0,\Sigma}Z(\mathbb{A}_F^\infty)) / F^\times$. It follows that the image of the norm map is exactly $S_\mathcal{O}(U_{0,\Sigma})^\times$.

The last part of the proposition follows since $\text{Stab}_1 \subset \Delta_\Sigma[\ell]$.

The following is Lemma 2.2 of [30]. The proof given in [30] works verbatim in our case (thanks to Theorem 4.10).

**Lemma 5.4** There is an isomorphism $S_\mathcal{O}(U_{0,\emptyset})_{m_\emptyset} \rightarrow S_\mathcal{O}(U_{0,\Sigma})_{m_\Sigma}$ inducing an isomorphism $\mathcal{T}(U_{0,\Sigma})_{m_\Sigma} \rightarrow \mathcal{T}(U_{0,\emptyset})_{m_\emptyset}$.

Using the fact that the rings in consideration are semi-local, reduced and complete (they are finite flat $\mathbb{Z}_\ell$-algebras), and Theorem 4.10 we get the following:

**Corollary 5.5**

1. There is an isomorphism $S_\mathcal{O}(U_{1,\Sigma})_{m_\Sigma,\Delta_\Sigma} \rightarrow S_\mathcal{O}(U_{1,\emptyset})_{m_\emptyset}$. This isomorphism is compatible with the map on Hecke algebras $\mathcal{T}(U_{1,\Sigma})_{m_\Sigma} \rightarrow \mathcal{T}(U_{1,\emptyset})_{m_\emptyset}$ which sends:

- $T_x$ to $T_x$ for $x$ not dividing $\ell n_\Sigma$,
- $\langle h \rangle$ to 1 for $h \in \Delta_\Sigma$, and
- $U_{\infty_x}$ to $A_x$ for $x \in \Sigma$ where $A_x$ is the unique root of $X^2 - T_x X + \mathbb{N}_x$ in $\mathcal{T}(U_{1,\emptyset})_{m_\emptyset}$ congruent to $\alpha_x$ (mod $m_\emptyset$).

2. The surjection $S_\mathcal{O}(U_{1,\Sigma})_{m_\Sigma} \rightarrow S_\mathcal{O}(U_{1,\emptyset})_{m_\emptyset}$ given by composing the norm map with the isomorphism of the preceding lemma factorizes as the composite of $S_\mathcal{O}(U_{1,\Sigma})_{m_\Sigma,\Delta_\Sigma} \rightarrow H_\Sigma$ and $H_\Sigma \rightarrow S_\mathcal{O}(U_{1,\emptyset})_{m_\emptyset}$.

where:

- $H_\Sigma$ is a $\mathcal{T}(U_{1,\Sigma})_{m_\Sigma}$-algebra and the maps are compatible with the algebra structures, and
- $H_\Sigma$ is a free $\mathcal{O}[\Delta_\Sigma/\Delta_\Sigma[\ell]]$ module.

We apply the above corollary to the sets $\Sigma_n$ produced by Theorem 5.3. Applying the ‘patching modules’ result of Diamond [2] and Fujivara [11] (Theorem 5.2 above), we get the following result.
Theorem 5.6 The natural map
\[ R_\emptyset \longrightarrow T(U_0)_{m_\emptyset} \]
is an isomorphism of complete intersection rings and the module \( S_\mathcal O(U_0)_{m_\emptyset} \) is free over \( T(U_0)_{m_\emptyset} \).

6 Non-minimal level

The proof of the result in the non-minimal case given in [30] remains valid in our case. We shall only give a sketch. Throughout this section, we keep the various assumptions (and notation) of the last section.

Fix a homomorphism \( \pi_\emptyset : R_\emptyset \twoheadrightarrow \mathcal O \).

We now let \( \Sigma \) be a finite set of primes of \( F \) not containing any primes above \( \ell \).

We denote by \( \pi_\Sigma \) the surjection \( R_\Sigma \twoheadrightarrow \mathcal O \) obtained by taking the composite of \( R_\Sigma \twoheadrightarrow R_\emptyset \twoheadrightarrow \mathcal O \) where the first map is the one given by the universal property of \( R_\Sigma \) and the second map is \( \pi_\emptyset \).

We shall denote the kernel of \( \pi_\Sigma \) by \( P_\Sigma \).

Let \( n_\Sigma = \prod_{x \in \Sigma} x^2 \), and let \( U_\Sigma = U_{\{1\}}(n_\Sigma) \). Also, let \( m_\Sigma \) be the maximal ideal of \( T_\mathcal O(U_\Sigma) \) corresponding to our residual representation \( \rho \).

We denote by \( T_\Sigma \) the localization \( T_\mathcal O(U_\Sigma)_{m_\Sigma} \), and write \( S_\Sigma \) for the \( T_\Sigma \)-module \( S_\mathcal O(U_\Sigma)_{m_\Sigma} \).

We then have the following.

Theorem 6.1 The natural map \( R_\Sigma \twoheadrightarrow T_\Sigma \) is an isomorphism of complete intersection rings and \( S_\Sigma \) is free over \( T_\Sigma \).

To prove the theorem, one needs to check (by Theorem 2.4 of [7]) that the order of \( P_\Sigma/P_\Sigma^2 \) divides the order of \( S_\Sigma \) defined as \( S_\Sigma = S_{\Sigma}[P_\Sigma] \oplus S_{\Sigma}[\text{Ann}_{T_\Sigma}P_\Sigma] \).

A standard computation shows that the order of \( P_\Sigma/P_\Sigma^2 \) divides
\[ \# \left( \frac{\mathcal O}{\mathcal O/(1-Nx)(T_x^2-(1+Nx)^2)} \right), \]
and we shall prove that this expression is the order of \( \Omega_\Sigma \).

Note that \( S_{\Sigma}[P_\Sigma] \) is a free \( \mathcal O \)-module of rank 1. Fix a perfect symmetric \( \mathcal O \)-valued \( \mathcal O \)-bilinear pairing \( \langle , \rangle_\Sigma \) on \( S_{\Sigma}[P_\Sigma] \), and let \( j_\Sigma : S_{\Sigma}[P_\Sigma] \hookrightarrow S_\Sigma \) be the natural inclusion. Also, define a pairing \( \langle , \rangle_\Sigma \) on \( S_\Sigma \) by
\[ \langle f_1, f_2 \rangle_\Sigma = \langle f_1, w_{\Sigma} f_2 \rangle \]
where \( \langle , \rangle \) is the standard pairing, and \( w_\Sigma \in \text{GL}_2(\mathbb A^\infty_F) \cong (D \otimes \mathbb Q \mathbb A^\infty)^\times \) is the element defined by
\[ w_{\Sigma,x} = \begin{cases} \text{identity}, & \text{if } x \notin \Sigma, \\ \begin{pmatrix} 0 & 1 \\ 2x & 0 \end{pmatrix}, & \text{if } x \in \Sigma. \end{cases} \]
This new pairing is perfect, and the Hecke operators are self-adjoint with respect to $\langle \cdot , \cdot \rangle_{\Sigma}$.

Now let $x$ be a prime not dividing $n_{\Sigma}$. There is a well-defined map

$$i_x : S_{\Sigma} \to S_{\Sigma \cup \{x\}}$$

which is obtained from the map sending $f \in SO(U_{\Sigma})$ to

$$(Nx)f - \begin{pmatrix} 1 & 0 \\ 0 & \sigma_x \end{pmatrix} T_x f + \begin{pmatrix} 1 & 0 \\ 0 & \sigma_x^2 \end{pmatrix} f \in SO(U_{\Sigma \cup \{x\}}).$$

Under this map, the image of $S_{\Sigma}[P_{\Sigma}]$ is contained in $S_{\Sigma \cup \{x\}}[P_{\Sigma \cup \{x\}}]$. We denote by $\tilde{i}_x$ the resulting map from $S_{\Sigma}[P_{\Sigma}]$ to $S_{\Sigma \cup \{x\}}[P_{\Sigma \cup \{x\}}]$.

We then have the following.

- Let $i_x^*$ be the adjoint of $i_x$ with respect to the pairings $\langle \cdot , \cdot \rangle_{\Sigma}$ and $\langle \cdot , \cdot \rangle_{\Sigma \cup \{x\}}$. The composite $i_x^* \circ i_x$ is equal to $N_x(1 - N_x)(T_x^2 - (1 + N_x)^2)$.

- $i_x(S_{\Sigma}[P_{\Sigma}]) = S_{\Sigma \cup \{x\}}[P_{\Sigma \cup \{x\}}]$. This follows from Ihara’s lemma (see Lemma 3.1 of [30]).

- Let $j_{\Sigma}^*$ be the adjoint of $j_{\Sigma}$ with respect to the pairings $\{ \cdot , \cdot \}$ and $\{ \cdot , \cdot \}_{\Sigma \cup \{x\}}$. It induces an isomorphism

$$j_{\Sigma}^* : \Omega_{\Sigma} \sim \frac{S_{\Sigma}[P_{\Sigma}]}{j_{\Sigma}^* S_{\Sigma}[P_{\Sigma}]}.$$

- Let $\tilde{i}_x^*$ be the adjoint of $\tilde{i}_x$ with respect to the pairings $\{ \cdot , \cdot \}_{\Sigma}$ and $\{ \cdot , \cdot \}_{\Sigma \cup \{x\}}$. It is an isomorphism, and we have $\tilde{i}_x^* \circ j_{\Sigma \cup \{x\}} = j_{\Sigma}^* \circ i_x^*$.

It follows that

$$\#\Omega_{\Sigma} = \#\Omega_0 \prod_{x \in \Sigma} \#(O/(1 - N_x)(T_x^2 - (1 + N_x)^2)O).$$

The result in the minimal case implies that $\#\Omega_0 = \#(P_{\emptyset}/P_{\emptyset}^2)$, and hence that

$$\frac{#P_{\Sigma}}{#P_{\emptyset}^2} \#\Omega_{\Sigma}.$$

### 7 Modularity of Galois representations and elliptic curves

We now collect the results of the preceding two sections.

Let $F$ be a totally real, finite extension of $Q$. Let $O$ be the ring of integers in a finite extension of $Q_\ell$ where $\ell$ is an odd prime, and let $k$ be its residue field. We suppose that we are given continuous representations

$$\rho_i : G_F \to GL_2(O), \quad i = 1, 2$$

satisfying the following properties:
• $\rho_i$ ($i = 1, 2$) is an odd representation unramified outside finitely many primes;
• $\det \rho_1 = \det \rho_2 = \epsilon_\ell$ where $\epsilon_\ell$ is the $\ell$-adic cyclotomic character.
• The residual representations $\overline{\rho}_i : G_F \to GL_2(k)$ are equivalent and are absolutely irreducible. We denote the residual representation by $\overline{\rho}$.

**Theorem 7.1** With notations as in the preceding paragraph, we make the following assumptions.

• The restriction of $\overline{\rho}$ to the absolute Galois group of $F(\zeta_\ell)$ is absolutely irreducible; furthermore, if $\ell = 5$ and $\Proj \overline{\rho}_{|\Gal(F/F(\zeta_\ell))}$ then $[F(\zeta_\ell) : F] = 4$.
• (Conditions at $\ell$.) Let $v$ be any prime of $F$ dividing $\ell$, and let $I_v$ be the inertia group of $F_v$. We assume:
  1. $\overline{\rho}|_{I_v} \sim \Omega_2|_{I_v}$, where $\Omega_2$ is the second fundamental character of the inertia group of $\mathbb{Q}_\ell$.
  2. Let $m$ be the maximal ideal of $\mathcal{O}$, and let $\overline{\rho}_{i,n}$ be the reduction of $\rho_i$ modulo $m^n$. Then $\overline{\rho}_{i,n}|_{F_v}$ is finite flat.
• The ramification index of $F$ at any prime above $\ell$ is less than or equal to $\ell - 1$.

Under these assumptions, the modularity of $\rho_1$ implies the modularity of $\rho_2$.

**Proof.** We can find a totally real, finite soluble extension $F'/F$ such that:

• The extension $F'/F$ is unramified at primes dividing $\ell$.
• $\overline{\rho}|_{G_{F'}}$ satisfies Assumption 5.1 (For this, we need to use the modularity of $\rho_1$ along with the base change results in [27]).

It follows that $\rho_2|_{G_{F'}}$ is modular. Langlands’ cyclic base change then shows that $\rho_2$ is modular. $\Box$

In section 9 we will give some applications to the modularity of elliptic curves. However, let us remark here that Theorem 7.1 will not apply in general to all supersingular curves, as the first condition at $\ell$ will not be satisfied in general. Indeed, let $F = \mathbb{Q}(\sqrt{3})$, and let $E$ denote the elliptic curve

$$y^2 = x^3 + 3x^2 + x + 1.$$  

The curve has discriminant $32(3\sqrt{3} - 14)$, and hence has good reduction at the prime $\sqrt{3}$ above 3. On the other hand, it is easy to show that multiplication by 3 on the group law of an elliptic curve

$$y^2 = x^3 + a_2x^2 + a_4x + a_6$$  

is given by  

$$[3]t = 3t - 8a_2t^3 + \cdots,$$

so that the curve above has supersingular reduction at $\sqrt{3}$, as $v_3(a_2) = v_3(\sqrt{3}) > 0$, showing that the formal group at 3 has height 2. As in Serre [22], Proposition
10, the action of tame inertia on the 3-torsion points is given by 2 copies of the fundamental character of level 1, rather than by the fundamental character of level 2.

Serre’s argument also shows that in order that the mod 3 representation of the curve $E$ be given (on tame inertia) by the fundamental character of level 2, it is necessary and sufficient that the Newton polygon of the multiplication-by-3 map on the formal group should consist of a single line from $(1, e)$ to $(9, 0)$. This is automatic when $e = 1$, but if $e > 1$, then other situations may arise, as above.

It follows that our main result can apply to all supersingular curves defined over fields $F$ unramified at 3, as well as to many examples of curves defined over more general fields.

8 Applications I

**Theorem 8.1** Let $\rho : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \rightarrow GL_2(\mathbb{F}_7)$ be an absolutely irreducible, continuous, odd representation. If the projective image of $\rho$ is insoluble, we also assume that:

- The projective image of inertia at 3 has odd order.
- The determinant of $\rho$ restricted to the inertia group at 7 has even order.

Then $\rho$ is modular.

**Sketch of proof.** Of course, we need only consider the case when the image of $\rho$ is insoluble. Moreover by [17], we can assume that the restriction of $\rho$ to a decomposition group at 7 is irreducible. Twisting by a quadratic character, we can also assume that $\rho|_{I_7}$ is equivalent to $\omega_2 \oplus \omega_2^7$ or $\omega_2^{13} \oplus \omega_2^{7,13}$ where $\omega_2 : I_7 \rightarrow \mathbb{F}_7^*$ is the second fundamental character. Applying the axiomatic formulation of Ramakrishna’s result in [29], together with Theorems 3.2.1, 4.2.1 of [4], one deduces the existence of a continuous, odd representation

$$\rho : \text{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}) \rightarrow GL_2(\mathbb{Z}_7)$$

lifting $\rho$, unramified outside finitely many primes, determinant the cyclotomic character times a finite order character, and such that the Artinian quotients $\rho$ (mod $7^n$) are finite flat when restricted to the absolute Galois group of $\mathbb{Q}_7(7^{1/4})$. Assuming the existence of a totally real soluble extension $F/\mathbb{Q}$ such that $\rho|_{G_F}$ is modular and the ramification index of $F/\mathbb{Q}$ at 7 is at most 6, one deduces the modularity of $\rho$ by Theorem 7.1 and Langlands’ cyclic base change.

We now explain how to find such a field $F$. Firstly, we can find a finite soluble, totally real extension $F_1/\mathbb{Q}$ and a quadratic twist of $\rho|_{G_{F_1}}$, which we denote by $\bar{\rho}$, such that the following conditions are satisfied.

- The determinant of $\bar{\rho}$ is the mod 7 cyclotomic character.
- Conditions at 3: Let $v$ be any prime of $F_1$ above 3, and let $D_v$ be a decomposition group at $v$.
  - $\bar{\rho}$ is trivial on $D_v$.
  - The ramification index of $F_{1,v}/\mathbb{Q}_3$ is odd.

22
• Conditions at 7: Let $v$ be any prime of $F_1$ above 7, and let $D_v$, $I_v$ be the decomposition and inertia groups at $v$. Then, the ramification index of $F_{1,v}/\mathbb{Q}_7$ is exactly 4. Furthermore, we have $\overline{\rho}_{I_{F_{1,v}}} \cong (\omega_2 \oplus \omega_7^3)|_{I_{F_{1,v}}}$.

We denote by $X(\overline{\rho})$ the (completed) moduli space of elliptic curves with mod 7 representation symplectically isomorphic to $\overline{\rho}$ (see [17] for details). The canonical divisor embeds $X(\overline{\rho})$ as a quartic curve in $\mathbb{P}^3_{F_1}$.

For each prime $v$ of $F_1$ dividing $3\infty$, we can find a finite unramified extension $F_v/F_{1,v}$ and a line $L_v$ defined over $F_{1,v}$ such that $L_v$ cuts $X(\overline{\rho})/F_v$ at four distinct points all of which are defined over $F_v$. Moreover, the elliptic curves corresponding to these four points all have good ordinary reduction when $v|3$. (See the fourth paragraph in section 5 of [17].) For primes above 7, we have the following lemma:

**Lemma 8.2** Let $v$ be a prime of $F_1$ above 7. We can find a finite Galois extension $F_v/F_{1,v}$ and an $F_v$-rational line $L_v$ such that the following holds.

- $L_v$ cuts $X(\overline{\rho})/F_v$ at four distinct points all of which are defined over $F_v$.
- The ramification index of $F_v/\mathbb{Q}_7$ is at most 4. The four points of intersection are all elliptic curves with good supersingular reduction.

Assuming the above lemma, intersecting $X(\overline{\rho})$ with a line over $F_1$ which is $v$-adically close to $L_v$ for each $v|3.7.\infty$ gives the following: There is a finite, soluble, totally real $F \supset F_1 \supset \mathbb{Q}$, and an elliptic curve $E/F$ satisfying the following conditions.

- $\overline{\rho}_{E,7} \sim \overline{\rho}_{G_F}$ and $\overline{\rho}_{E,3} : GL_2(\mathbb{F}_3)$ is surjective.
- Conditions at primes $v$ dividing 3: $E$ has good ordinary reduction at every prime above 3 and the ramification index of $F$ at 3 is odd.
- Conditions above 7: $F/F_1$ is unramified at every prime above 7 and $E$ has good supersingular reduction at every prime above 7.

The elliptic curve $E$ is modular by a result of Skinner and Wiles ([20]), and therefore $\mathcal{P}$ is also modular.

**Proof of Lemma 8.2.** The modular curve $X(\omega_2 \oplus \omega_7^3)/\mathbb{Q}_7$ is isomorphic to $X(\overline{\rho})$ over $\mathbb{Q}_7^\text{nr}(\sqrt[7]{7})$. The elliptic curve $y^2 = x^3 + x$ has $j$-invariant 1728 and so has supersingular reduction. Taking a cyclic degree 3 isogeny of $E$ if necessary, we can assume that $X(\omega_2 \oplus \omega_7^3)/\mathbb{Q}_7^\text{nr}$ contains an elliptic curve $E$ having good supersingular reduction and with $j$-invariant 1728. Let us denote this point by $P$. From the geometry of the Klein quartic (see the proposition in section 2 of [4]), we see that there is a unique involution (in the automorphism group) fixing $P$. The normalizer of this involution is a Sylow 2-subgroup, and the orbit of $P$ when acted on by the normalizer has size exactly 4. Furthermore, they (the points in the orbit) lie on a unique line.

We can thus find a unique line $L$ passing through $P$ such that:

- $L$ is defined over $\mathbb{Q}_7^\text{nr}$,
- $L$ passes through four distinct points of $X(\omega_2 \oplus \omega_7^3)$ whose $j$-invariants are 1728.
We claim that two of these points are already defined over \( \mathbb{Q}_{nr} \). We have the point \( P \) with corresponding elliptic curve \( E \). Note that \( E \) has complex multiplication by \( \mathbb{Z}[i] \) (and the endomorphism ring is already defined over \( \mathbb{Q}_{nr} \)). We now check that the isogeny \( E^{2} \to E \) gives us another point of intersection (which is obviously defined over \( \mathbb{Q}_{nr} \)). This can be checked over \( \mathbb{C} \), and follows from the following observations.

- The involution \( \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \in PSL_2(\mathbb{F}_7) \) fixes \( (\{1/7, i/7\}, \mathbb{C}/\mathbb{Z} + i\mathbb{Z}) \in X(7)(\mathbb{C}) \).

- \( \begin{pmatrix} 2 & 2 \\ -2 & 2 \end{pmatrix} \) is in the normalizer of \( \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix} \) and sends \( (\{1/7, i/7\}, \mathbb{C}/\mathbb{Z} + i\mathbb{Z}) \) to \( (\{2 - 2i/7, 2 + 2i/7\}, \mathbb{C}/\mathbb{Z} + i\mathbb{Z}) \).

Thus each of the four points of intersection are defined over \( \mathbb{Q}_{nr}^{\sqrt{7}} \). The Sylow 2-subgroup which acts transitively on these four points is dihedral; in terms of generators and relations, it is given by \( \langle \alpha, \beta \mid \alpha^4 = \beta^2 = e, \beta \alpha \beta = \alpha^3 \rangle \).

The unique involution which stabilizes \( P \) is \( \alpha^2 \), and it is defined over \( \mathbb{Q}_{nr} \). The other three points are given by \( \alpha(P), \beta(P) \) and \( \alpha \beta(P) \).

We now check that \( \alpha, \beta \) are defined over \( \mathbb{Q}_{nr}^{\sqrt{7}} \). If \( \sigma \in G_{\mathbb{Q}_{nr}^{\sqrt{7}}} \), we have \( (\sigma * \beta)(P) = \sigma(\beta(\sigma^{-1}P)) = \beta(P) \). Therefore, we have \( \sigma * \beta = \alpha^{2i(\sigma)} \beta \) where

\[
i : G_{\mathbb{Q}_{nr}^{\sqrt{7}}} \to \mathbb{Z}/2\mathbb{Z}
\]

is a continuous homomorphism which necessarily factors through \( \mathbb{Q}_{nr}^{\sqrt{7}} \). Similarly for \( \alpha \). We can thus conclude that all the four points of intersection have good supersingular reduction \( \mathbb{Q}_{nr}^{\sqrt{7}} \).

Finally, it follows that we can find a line defined over an extension of \( F_{1,v} \) with absolute ramification index 4 which cuts \( X(\bar{\rho}) \) at four distinct supersingular points, all defined over that extension. Take \( F_v \) to be the Galois closure of the extension thus constructed, and take \( L_v \) to be the line \( L_{f,F_v} \).

\[\square\]

9 Applications II

The aim of this section is to study the modularity of elliptic curves over certain totally real fields, using Theorem 7.1. Our main results are given by Propositions 9.2 and 9.3. For the particular example of the field \( \mathbb{Q}(\sqrt{2}) \), we can prove more; the analogue of the switch between \( p = 3 \) and \( p = 5 \) used by Wiles (§5) holds, and we can use existing results, together with the new results in this paper, to deduce the modularity of all semistable elliptic curves over \( \mathbb{Q}(\sqrt{2}) \).
In [12], it is explained that this implies a version of Fermat’s Last Theorem over $\mathbb{Q}(\sqrt{2})$. Further calculations in [12] show that $\mathbb{Q}(\sqrt{2})$ is the only real quadratic field for which one can hope to generalise the methods of Ribet and Wiles to prove such a result. It seems remarkable to us that there are any fields other than $\mathbb{Q}$ for which all the numerology allows us to prove generalisations of Fermat’s Last Theorem.

We begin by proving results for more general fields. We start with a preliminary lemma.

**Lemma 9.1** Let $p$ be equal to 3 or 5, and let $F$ be a totally real number field in which $p$ is unramified. Let $E$ be an elliptic curve over $F$ with good supersingular reduction at some place $v|p$. Then

$$\overline{\rho}_{E,p} \big|_{\text{Gal}(\overline{F}/F(\sqrt{-1}(p-1)/2p))}$$

is absolutely irreducible.

**Proof.** The presence of a non-trivial complex conjugation shows that irreducibility is the same as absolute irreducibility for odd $\text{GL}_2(F_p)$-valued representations of totally real fields. The lemma then follows easily when $p = 5$.

We now do $p = 3$. Suppose, for a contradiction, that the conclusion of the lemma fails. Let $I_v$ be a decomposition group at $v$. Since the image $\overline{\rho}_{E,3}(I_v)$ is cyclic of order 8, it follows that the image $\overline{\rho}_{E,3}(\text{Gal}(\overline{F}/F(\sqrt{-3})))$ is an abelian group of order 8.

The Sylow 2-subgroup of $\text{GL}_2(F_3)$ is the group

$$\langle c, \tau | c^2 = \tau^8 = 1, \ c\tau = \tau^3c \rangle,$$

and we may suppose that

$$c = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \ \tau = \begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}.$$

Since the image of $\text{Gal}(K/F(\sqrt{-3}))$ is in $\text{SL}_2(F_3)$, it must in fact be the subgroup generated by $\tau^2$ and $c\tau$. This subgroup is non-abelian, giving the desired contradiction. □

The next two propositions prove modularity of many elliptic curves over certain totally real fields, using Theorem 7.1.

**Proposition 9.2** Let $F$ be a totally real number field in which 3 is unramified, and let $E$ be an elliptic curve over $F$ with good supersingular reduction at primes above 3. Then $E$ is modular.

**Proof.** We proceed in several steps. By the result of Langlands and Tunnell, we know that $\overline{\rho}_{E,3}$ is modular. However, in order to apply Theorem 7.1 we need to produce a modular lift with level coprime to 3.

**Step I:** By Langlands’ cyclic base change, we need only prove the result over a totally real soluble extension. In particular, making an appropriate base change if necessary, we can assume that $\overline{\rho}_{E,3}|_{D_v}$ is trivial for any prime $v|5$.

**Step II:** We can find an elliptic curve $E'$ over $F$ such that
• \( \overline{\rho}_{E,3} \sim \overline{\rho}_{E',3} \).

• \( \overline{\rho}_{E',5} \) has insoluble image,

• \( E' \) has good ordinary reduction at every prime above 5 and

\[
\overline{\rho}_{E',5}|_{D_v} \cong \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \text{ for any } v \nmid 5
\]

with distinct characters on the diagonal,

• \( E' \) has good reduction at primes above 3.

If we can show that \( E' \) is modular, then \( \rho_{E',3} \) will be a modular lift of \( \overline{\rho}_{E,3} \) of the ‘right level’; we can then use Theorem 7.1 to conclude that \( \rho_{E,3} \) is modular.

In order to show that \( E' \) is modular, we want to make use of its 5-adic representation and apply the results in [26]. For this, we need to produce a nearly ordinary modular lift of \( \overline{\rho}_{E',5} \). Again, we can work over totally real soluble extensions.

Step III: We can assume that \( \overline{\rho}_{E',5} \) is trivial when we restrict to primes above 3. We can then find a second elliptic curve \( E'' \) such that

• \( \overline{\rho}_{E'',5} \sim \overline{\rho}_{E',5} \),

• \( \overline{\rho}_{E'',3} : G_F \longrightarrow GL_2(\mathbb{F}_3) \) is surjective,

• \( E'' \) has split multiplicative reduction at every prime above 3 and

\[
\overline{\rho}_{E'',5}|_{D_v} \cong \begin{pmatrix} * & * \\ 0 & * \end{pmatrix} \text{ for any } v \nmid 3
\]

with distinct characters on the diagonal,

• \( E'' \) has good ordinary reduction at primes above 5.

By Theorem 7.1, \( E'' \) is modular.

Since \( \rho_{E'',3} \) is a nearly ordinary modular lift, it follows that \( \rho_{E',3} \) is modular. \( \square \)

**Proposition 9.3** Let \( F \) be a totally real number field in which 3 and 5 are unramified. Let \( E \) be an elliptic curve over \( F \) with semistable reduction at primes above 3 and 5. Further, assume that \( E \) has good supersingular reduction at primes above 5 and that \( \overline{\rho}_{E,5}|_{\text{Gal}(F/F(\sqrt{5}))} \) is irreducible. Then \( E \) is modular.

**Proof.** Going up to a soluble totally real field (without changing ramification at 3 and 5) if necessary, we can assume that \( \overline{\rho}_{E,5}|_{D_v} \) is trivial for places \( v \mid 3 \) where \( E \) has good reduction. Then using the twisted modular curve \( X(E[5])/F \), we can find an elliptic curve \( E'/F \) such that

• \( \overline{\rho}_{E',5} \sim \overline{\rho}_{E,5} \),

• \( E' \) has the same reduction type as \( E \) at primes above 5,

• \( E' \) is a Tate curve at primes above 3, and

• \( \overline{\rho}_{E',3} : G_F \longrightarrow GL_2(\mathbb{F}_3) \) is surjective.
It follows that $\rho_{E', 3}$ is modular, and $\rho_{E', 5}$ is a modular lift of $\overline{\rho}_{E, 5}$ of the ‘right level’. Therefore, using either Theorem 5.1 of [26] or Theorem 7.1 of this article, it follows that $\rho_{E', 5}$ is modular.

Having proven some results over general fields, we now specialise to the case $F = \mathbb{Q}(\sqrt{2})$, for which, as we shall see, there is also a version of the switch between 3 and 5 used by Wiles ([32], §5). In particular, this allows us to prove the modularity of all semistable elliptic curves over $\mathbb{Q}(\sqrt{2})$.

**Proposition 9.4** Let $E$ be a semistable elliptic curve over $\mathbb{Q}(\sqrt{2})$. Let $p$ be either 3 or 5. If $\overline{\rho}_{E, p}$ is irreducible, then

$$\overline{\rho}_{E, p}|_{\text{Gal}(F/F)}(\sqrt{(-1)^{(p-1)/2}})$$

is absolutely irreducible.

**Proof.** Suppose the proposition fails to hold. Then $p$ does not divide the order of $\overline{\rho}_{E, p}(\text{Gal}(F/F))$, and so the semistability condition implies that $\overline{\rho}_{E, p}$ is unramified at primes not dividing $p$. Further, by Lemma 9.3 we see that $E$ has good ordinary or multiplicative reduction at $p$. Therefore, we must have

$$\overline{\rho}_{E, p}|_{I_p} \sim \begin{pmatrix} \tau_p & 0 \\ 0 & 1 \end{pmatrix}$$

where $\tau_p$ is the mod $p$ cyclotomic character. (Note also that 3 and 5 are inert in $\mathbb{Q}(\sqrt{2})$.)

Let $K$ be the splitting field of $\overline{\rho}_{E, p}$, and let $\zeta_p$ be a primitive $p$th root of unity. Then $K$ is an everywhere unramified abelian extension of $\mathbb{Q}(\sqrt{2}, \zeta_p)$. The class number of $\mathbb{Q}(\sqrt{2}, \zeta_p)$ is then checked to be equal to 1 for both $p = 3$ and $p = 5$ (we used PARI to verify this), giving the required contradiction.

**Proposition 9.5** The modular curve $X_0(15)$ has exactly eight $\mathbb{Q}(\sqrt{2})$-rational points. Four of these are cusps. The remaining four are elliptic curves with additive reduction at 5.

**Proof.** $X_0(15)$ is an elliptic curve, and, using Cremona’s tables [5], we can find an explicit equation for it. The rank of $X_0(15)$ regarded as an elliptic curve over $\mathbb{Q}(\sqrt{2})$ is the sum of its rank over $\mathbb{Q}$ and the rank (over $\mathbb{Q}$) of its quadratic twist. An equation of $X_0(15)$ over $\mathbb{Q}$ is $y^2 + xy + y = x^3 + x^2 - 10x - 10$, and its quadratic twist over $\mathbb{Q}(\sqrt{2})$ is $y^2 = x^3 + x^2 - 641x - 3105$, which is curve 960G3 in Cremona’s tables. Both curves have rank 0 over $\mathbb{Q}$, and it follows that $X_0(15)$ has rank 0 over $\mathbb{Q}(\sqrt{2})$. Thus all of its points over $\mathbb{Q}(\sqrt{2})$ are torsion points, and we can count them by considering the number of points in various residue fields of $\mathbb{Q}(\sqrt{2})$ (as in [24], VII.3). Note that 7 splits in $\mathbb{Q}(\sqrt{2})$, so $\mathbb{Q}(\sqrt{2})$ has a residue field isomorphic to $\mathbb{F}_7$. Now $X_0(15)$ has good reduction at the primes above 7, and $|X_0(15)(\mathbb{F}_7)| = 8$. By [24], VII.3.1(b), we see that the size of the torsion group over $\mathbb{Q}(\sqrt{2})$ divides 8. However, we know that $X_0(15)$ has 8 points over $\mathbb{Q}$, all of which are torsion, and so these can be the only points on $X_0(15)$ defined over $\mathbb{Q}(\sqrt{2})$. Of these, 4 are cusps, and the remaining 4 correspond to elliptic curves over $\mathbb{Q}$ which have additive reduction at 5 (curves 50A1, 50A2, 50A3 and 50A4 in Cremona’s tables). Since 5 is unramified in $\mathbb{Q}(\sqrt{2})/\mathbb{Q}$, these curves continue to have additive reduction at 5 over $\mathbb{Q}(\sqrt{2})$, and so are also not semistable. It follows that none of the $\mathbb{Q}(\sqrt{2})$-rational points on $X_0(15)$ correspond to semistable elliptic curves. □
Theorem 9.6 Any semistable elliptic curve over \( \mathbb{Q}(\sqrt{2}) \) is modular.

Proof. Let \( E \) be a semistable elliptic curve over \( \mathbb{Q}(\sqrt{2}) \). By Proposition [9.5] one of \( \rho_{E,3} \) or \( \rho_{E,5} \) will be absolutely irreducible. The case where \( \rho_{E,3} \) is absolutely irreducible and \( E \) has good ordinary reduction or multiplicative reduction at 3 follows from Theorem 5.1 of [26] (using Proposition 9.4 to check the hypothesis that \( \rho_{E,3} |_{\text{Gal}(F/F(\sqrt{-3}))} \) is absolutely irreducible). If \( \rho_{E,3} \) is absolutely irreducible and \( E \) has supersingular reduction, then the modularity of \( E \) follows from Proposition 9.2. Otherwise \( \rho_{E,5} \) is irreducible, and modularity follows by switching to an elliptic curve \( E' \) as in the proof of Proposition 9.3. By the previous argument, \( E' \) is modular, so that \( \rho_{E',5} \cong \rho_{E,5} \) is modular. If \( E \) has good ordinary reduction or multiplicative reduction at 5, modularity follows from Theorem 5.1 of [26], again using Proposition 9.4 to check that the hypotheses of this theorem hold. Otherwise, \( E \) has good supersingular reduction at 5. As remarked at the end of §7 since 5 is unramified in \( \mathbb{Q}(\sqrt{2}) \), the Galois representation \( \rho_{E,5} \) has the form given in Theorem 7.1; this theorem now implies that \( E \) is modular, as required. \( \square \)

Remark 9.7 In fact, \( \mathbb{Q}(\sqrt{2}) \) is not the only real quadratic field for which all the numerology is valid to deduce modularity. Indeed, let \( F = \mathbb{Q}(\sqrt{17}) \). Note that 3 and 5 are inert in \( F \). Again using PARI, one can verify that the class numbers of \( F(\zeta_3) \) and \( F(\zeta_5) \) are both 1, so that the analogue of Proposition 9.4 will hold also for \( F \). (We suspect that this might be the only other real quadratic field with this property.) Next, the quadratic twist of \( X_0(15) \) to \( F \) is curve 4335D3 in Cremona's tables, which has rank 0 (and 4 points defined over \( \mathbb{Q} \)), so that \( X_0(15) \) has rank 0 over \( F \). We can count the \( \mathbb{Q}(\sqrt{17}) \)-rational points by counting the points in residue fields of \( F \) whose characteristic is a prime of good reduction for \( X_0(15) \). Since 13 and 43 both split in \( F \), and \( X_0(15) \) has 16 points in \( F_{13} \) and 40 points in \( F_{43} \), we see that the size of the torsion group of \( X_0(15) \) over \( F \) divides 8. Now one argues as in the case of \( \mathbb{Q}(\sqrt{2}) \) to see that all semistable elliptic curves over \( \mathbb{Q}(\sqrt{17}) \) are modular.

\section{The Honda system associated to a Raynaud scheme}

We describe the Honda system associated to a Raynaud scheme. We fix:

\begin{align*}
\mathbf{k} & : \text{a perfect field of odd characteristic } p, \\
W(\mathbf{k}), v & : \text{its Witt ring and normalized valuation } v \text{ (so } v(p) = 1), \\
\sigma & : \text{the Frobenius automorphism } \sigma : W(\mathbf{k}) \rightarrow W(\mathbf{k}).
\end{align*}

We also fix a finite field \( \mathbb{F} \) of order \( p^r \), and we assume that there is an injection \( \mathbb{F} \hookrightarrow \mathbf{k} \) of fields. There are \( r \) ‘fundamental characters’, indexed by a principal homogeneous space over \( \mathbb{Z}/r\mathbb{Z} \). We recall the definition (Définition 1.1.1 of [20]): these are maps \( \chi_i : \mathbb{F} \rightarrow W(\mathbf{k}) \) such that \( \chi_i|_{\mathbb{F}^\times} \) is a multiplicative character, \( \chi_i(0) = 0 \), and the composite

\[ \mathbb{F} \xrightarrow{\chi_i} W(\mathbf{k}) \xrightarrow{\text{mod } p^r} k \]

is a homomorphism of fields.
Given a multiplicative character $\chi : \mathbb{F}^\times \to W(k)^\times$, Raynaud defines a quantity $\omega_\chi$ in $W(k)$. Raynaud also defines, starting from a fundamental character, another quantity $\omega \in W(k)$ (which is then shown to be independent of the choice of fundamental character). We refer to equations 11 of [20] for the defining relations, and we recall that (Proposition 1.3.1 of [20]):

- Write $\chi$ (uniquely) as a product over fundamental characters $\prod_{i \in \mathbb{Z}/r\mathbb{Z}} \chi_i^{a_i}$ with $0 \leq a_i \leq p - 1$. Then
  $$\omega_\chi \equiv a_1! \ldots a_r! \pmod{p}.$$  
- $\omega \equiv p! \pmod{p^2}$.

Given two multiplicative characters $\chi' = \prod_{i \in \mathbb{Z}/r\mathbb{Z}} \chi_i^{a_i'}$ and $\chi'' = \prod_{i \in \mathbb{Z}/r\mathbb{Z}} \chi_i^{a_i''}$ with $0 \leq a_i', a_i'' \leq p - 1$ and such that $\chi' \chi'' = \chi_i$ for some $i \in \mathbb{Z}/r\mathbb{Z}$, we let $h$ be the unique integer such that $0 < h \leq r$ and

$$a_i' - h + a_i'' - h = p,$$

$$a_i' - k + a_i'' - k = p - 1 \quad \text{for} \quad 0 < k < h,$$

$$a_j' = a_j'' = 0 \quad \text{otherwise}.$$

Throughout we fix a Raynaud scheme $G$ over Spec $W(k)$, and we denote its coordinate ring by $A$. We also fix the following presentation of $A$: it is generated as a $W(k)$-algebra by $X_i$ with $i \in \mathbb{Z}/r\mathbb{Z}$ and relations

$$X_i^p = \delta_i X_{i+1} \text{ where } v(\delta_i) = 0 \text{ or } 1.$$ 

We also set $\gamma_j = \omega/\delta_j$ and denote by $\lambda_j$ the Teichmüller lift of $\gamma_j$. The multiplication map $\Delta : A \to A \otimes A$ is given by the formula

$$\Delta(X_i) = X_i \otimes 1 + 1 \otimes X_i + \sum_{\chi' \chi'' = \chi_i} \frac{\gamma_i - h \cdots \gamma_i - 1}{\omega_\chi' \omega_\chi''} \left( \prod_j X_j^{a_j'} \right) \otimes \left( \prod_j X_j^{a_j''} \right).$$

**Theorem A.1** Let $G/\text{Spec } W(k)$ be as above. Let $M$ be the $r$-dimensional $k$-vector space with basis given by $e_i, i \in \mathbb{Z}/r\mathbb{Z}$. Define Frobenius semi-linear maps $F, V : M \to M$ by setting

$$F(e_i) = \delta_i e_{i+1} \quad \text{and}$$

$$V(e_i) = \lambda_{i-1}^{p-1} e_{i-1},$$

on the basis elements $e_i$ and then extending semi-linearly. (So $F(\alpha v) = \sigma(\alpha) F(v)$ and $V(\alpha v) = \sigma^{-1}(\alpha) V(v)$ for $\alpha \in k$.) Let $L \subset M$ be the $k$-linear subspace of $M$ spanned by $\lambda_{i-1} e_i, i \in \mathbb{Z}/r\mathbb{Z}$. Then $(L, M)$ is the Honda system associated to $G$.  

---

29
Witt covectors

For \( n \geq 0 \), set
\[
W_n = W_n(X_0, \ldots, X_n) \overset{\text{def}}{=} X_0^p + pX_1^{p - 1} + \cdots + p^n X_n.
\]

There are polynomials
\[
S_n \in \mathbb{Z}[Y_0, Y_1, \ldots; Z_0, Z_1, \ldots]
\]
where \( S_0 = Y_0 + Z_0 \), and \( S_n \), for \( n \geq 1 \), satisfies the relation
\[
W_n(S_0, S_1, \ldots, S_n) = W_n(Y_0, Y_1, \ldots, Y_n) + W_n(Z_0, Z_1, \ldots, Z_n).
\]

We record the following for future use.

**Proposition A.2** Modulo the ideal \((p, Y_0^p, \ldots, Y_{n-2}^p, Z_0^p, \ldots, Z_{n-2}^p)\), we have
\[
S_n(Y_0, \ldots, Y_n; Z_0, \ldots, Z_n) = Y_n + Z_n + \sum_{i=1}^{p-1} \frac{Y_n^i Z_n^{p-i}}{i!(p-i)!} + \sum_{r=0}^{n-2} (-1)^{n-r} \left( (Y_{n-1} + Z_{n-1}) \cdots (Y_{r+1} + Z_{r+1}) \right)^{p-1} \sum_{i=1}^{p-1} \frac{Y_r^i Z_r^{p-i}}{i!(p-i)!}.
\]

**Proof.** We have
\[
S_n = Y_n + Z_n + \frac{Y_{n-1}^p + Z_{n-1}^p - S_{n-1}^p}{p} + \frac{Y_{n-2}^p + Z_{n-2}^p - S_{n-2}^p}{p^2} + \cdots
\]
Thus modulo \( X_i^p \), \( i \geq 0 \), we have
\[
S_n = Y_n + Z_n + \frac{Y_{n-1}^p + Z_{n-1}^p - S_{n-1}^p}{p}.
\]
Assume the proposition for \( n - 1 \). The right hand side of the above relation, modulo \((p, X_0^p, X_1^p, \ldots)\), is equal to
\[
Y_n + Z_n + \frac{Y_{n-1}^p + Z_{n-1}^p - (Y_{n-1} + Z_{n-1})^p}{p} - (Y_{n-1} + Z_{n-1})^{p-1} \sum_{r=0}^{n-2} (-1)^{n-1-r} \prod_{j=r+1}^{n-2} (Y_j + Z_j)^{p-1} \sum_{i=1}^{p-1} \frac{Y_r^i Z_r^{p-i}}{i!(p-i)!}.
\]
This proves the proposition. \( \square \)

**Definition A.3** We define \( \tilde{S}_{-n} \in \mathbb{F}_p[Y_{-n}, \ldots, Y_0; Z_{-n}, \ldots, Z_0] \) to be the polynomial
\[
Y_0 + Z_0 + \sum_{i=1}^{p-1} \frac{Y_i Z_i^{p-i}}{i!(p-i)!} + \sum_{r=2}^{n} (-1)^{r-1} \left( (Y_{-1} + Z_{-1}) \cdots (Y_{r-1} + Z_{r-1}) \right)^{p-1} \sum_{i=1}^{p-1} \frac{Y_r^i Z_r^{p-i}}{i!(p-i)!}.
\]
We have \( S_n(Y_{-n}, \ldots, Y_0; Z_{-n}, \ldots, Z_0) \equiv \tilde{S}_{-n} \mod (p, Y_{-2}^p, \ldots, Y_{-n}^p, Z_{-2}^p, \ldots, Z_{-n}^p) \).
The following definition is due to Fontaine ([10]).

**Definition A.4** For any finite $k$-algebra $R$, the group of $R$-valued Witt covectors $CW_k(R)$ is given by:

- As a set, the elements of $CW_k(R)$ are sequences
  \[
  \{ (\ldots, a_{-n}, \ldots, a_{-1}, a_0) : a_{-i} \in R \text{ is nilpotent for large } i \}.
  \]

- For $(a_{-i})_{i \geq 0}, (b_{-i})_{i \geq 0} \in CW_k(R)$, let
  \[
  c_{-n} = \lim_{m \to \infty} S_m(a_{-n-m}, \ldots, a_{-1}, b_{-n-m}, \ldots, b_{-1}).
  \]

  The sequence $(c_{-i})_{i \geq 0} \in CW_k(R)$, and the group law is
  \[
  (a_{-i})_{i \geq 0} + (b_{-i})_{i \geq 0} \overset{\text{def}}{=} (c_{-i})_{i \geq 0}.
  \]

- The identity element is $(\ldots, 0, 0)$. These give $CW_k(R)$ the structure of a commutative group (Proposition 1.4, Chapter II of [10]).

$CW_k(R)$ has a natural structure of a $W(k)$-module which, for $x \in k$, is given by
\[
[x](\ldots, a_{-n}, \ldots, a_{-1}, a_0) = (\ldots, x^{p^n}a_{-n}, \ldots, x a_{-1}, xa_0).
\]

Here, $[x]$ is the Teichmüller lift of $x$. The Frobenius and Verschiebung operators $F, V : CW_k(R) \to CW_k(R)$ are given by
\[
F(\ldots, a_{-n}, \ldots, a_{-1}, a_0) \overset{\text{def}}{=} (\ldots, a_{-n}^p, \ldots, a_{-1}^p, a_0^p), \quad \text{and}
\]
\[
V(\ldots, a_{-n}, \ldots, a_{-1}, a_0) \overset{\text{def}}{=} (\ldots, a_{-n+1}, \ldots, a_{-1}).
\]

These are additive, and they satisfy the relation $FV = VF = p$. As for compatibility with the $W(k)$-module structure, one has
\[
F \alpha = \sigma(\alpha) F \quad \text{and} \quad V \alpha = \sigma^{-1}(\alpha) V
\]
where $\sigma : W(k) \to W(k)$ is the Frobenius. In other words, the Witt covectors $CW_k(R)$ form a module over the Dieudonné ring $D_k = W(k)[F, V]$.

**The Dieudonné module of the special fibre**

We now calculate the Dieudonné module associated to the special fibre $G_k$. We know that this is a vector space over $k$ of dimension $r$.

Following [10], we need to calculate certain elements of $A_k$-valued Witt covectors. These elements are formal group homomorphisms from $G_k$ to $\hat{CW}_k$.

We will describe the ‘homomorphism’ condition shortly, but let us start with a candidate covector $a = (\ldots, a_{-n}, \ldots, a_0)$. Since $FV(a) = pa = 0$, we must have $a_{-n}^p = 0$ for $n \geq 1$. The comultiplication map
\[
\Delta : A_k \to A_k \otimes_k A_k
\]

gives us an $A_k \otimes_k A_k$-valued Witt covector
\[
\Delta(a) = (\ldots, \Delta(a_{-n}), \ldots, \Delta(a_0)).
\]
In $CW_k(A_k \otimes_k A_k)$, we also have the sum 
\[ a \otimes 1 + 1 \otimes a = (\ldots, a_{-n} \otimes 1, \ldots, a_0 \otimes 1) + (\ldots, 1 \otimes a_{-n}, \ldots, 1 \otimes a_0). \]

The ‘homomorphism’ condition is then 
\[ \Delta(a) = a \otimes 1 + 1 \otimes a. \]

We now define covectors 
\[ e_i = \left( \ldots, \gamma_{i-1}^{p-1} \cdot \ldots \gamma_{i-n}^{p-1} X_{i-n}, \ldots, \gamma_{i-1}^{p-1} X_{i-1}, X_i \right) \]
for $i \in \mathbb{Z}/r\mathbb{Z}$. Here we are viewing $X_i$ and $\gamma_j$ modulo $p$ (and so $\gamma_j^{p-n}$ is the mod $p$ reduction of $\sigma^{-n}(\gamma_j)$). We shall check (by a tedious, but entirely straightforward, calculation) that $e_i$ satisfies the ‘homomorphism’ condition. Note that $Fe_n = (\ldots, 0, \ldots, 0, X_{k-1}^p)$ as $X_{k-1}^p \neq 0 \mod p$ implies $\gamma_n \equiv 0 \mod p$.

We write $Y_i = X_i \otimes 1$ and $Z_i = 1 \otimes X_i$, and so 
\[ e_i \otimes 1 = (\ldots, \gamma_{i-1}^{p-1} Y_{i-1}, Y_i), \]
\[ 1 \otimes e_i = (\ldots, \gamma_{i-1}^{p-1} Z_{i-1}, Z_i). \]

**Lemma A.5**  
- For any $n \geq 0$, we have 
  \[ \gamma_{i-1} \gamma_{i-2} \cdots \gamma_{i-(n+1)} = \left( \left( \gamma_{i-1}^{p-1} \right)^{\gamma_{i-2}^{p-1}} \right) \cdots \left( \gamma_{i-1}^{p-1} \gamma_{i-2}^{p-1} \right) \right)^{p-1} \times \left( \gamma_{i-1}^{p-n} \gamma_{i-2}^{p-n} \right). \]

- For any $n \geq r - 1$, we have 
  \[ \Delta(X_i) = \widetilde{S^{-n}}(e_i \otimes 1; 1 \otimes e_i). \]

**Proof.** The first part is a simple manipulation of symbols; the third part follows from the second (for example, apply the $V$ operator).

We now prove the second part of the lemma. Since $X_k$ (resp. $Y_k, Z_k, \gamma_k$) is $X_{k+r}$ (resp. $Y_{k+r}, Z_{k+r}, \gamma_{k+r}$), it follows that the limit 
\[ \lim_{m \to \infty} S_m \left( \left( \gamma_{i-1}^{p-m} \cdots \gamma_{i-m}^{p-1} \right) Y_{i-m}, \ldots, Y_i; \left( \gamma_{i-1}^{p-m} \cdots \gamma_{i-m}^{p-1} \right) Z_{i-m}, \ldots, Z_i \right) \]
is equal to 
\[ \widetilde{S^{-r+1}}(e_i \otimes 1; 1 \otimes e_i) = \widetilde{S^{-n}}(e_i \otimes 1; 1 \otimes e_i) \] for any $n \geq r - 1$.

Using the first part, we see that $\widetilde{S^{-r+1}}$ is equal to 
\[ Y_i + Z_i + \gamma_{i-1} \sum_{j=1}^{p-1} \frac{Y_j^{j-1} Z_i^{p-j}}{j!(p-j)!} + \sum_{k=1}^{r-2} (-1)^k \left( \prod_{j=1}^{k+1} \gamma_{i-j} \right) \left( \prod_{j=1}^{k} (Y_{i-j} + Z_{i-j}) \right)^{p-1} \sum_{j=1}^{p-1} \frac{Y_j^{j-1} Z_i^{p-j}}{j!(p-j)!}. \]
Now
\[
(Y_{i-1} + Z_{i-1})^{p-1} \cdots (Y_{i-k+1} + Z_{i-k+1})^{p-1} \sum_{j=1}^{p-1} \frac{Y_{i-k}^j Z_{i-k}^{p-j}}{j!(p-j)!}
\]
\[
= \sum \frac{(-1)^{k-1}}{a_{i-1}! \cdots a_{i-k}! b_{i-1}! \cdots b_{i-k}!} Y_{i-1}^{a_{i-1}} \cdots Y_{i-k}^{a_{i-k}} Z_{i-1}^{b_{i-1}} \cdots Z_{i-k}^{b_{i-k}}
\]
where the sum is over
\[
\begin{cases}
0 \leq a_{i-1}, \ldots, a_{i-k+1} \leq p-1, & 1 \leq a_{i-k} \leq p-1, \\
\text{and}
\end{cases}
\]
\[
a_{i-j} + b_{i-j} = p-1, & j = 1, \ldots, k-1; & a_{i-k} + b_{i-k} = p.
\]

The second part of the lemma easily follows. \(\square\)

**Lemma A.6** The covectors \(e_1, \ldots, e_r\) are \(k\)-linearly independent.

**Proof.** First suppose that one of the \(\gamma_i\) is divisible by \(p\). Then each \(e_n\) has only finitely many non-zero terms. Applying the \(V\) operator, one reduces the linear independence of \(e_1, \ldots, e_1\) to the \(k\)-linear independence of \(X_1, \ldots, X_r\), which is clear.

In the remaining case, we have \(A_k = k[X_1, \ldots, X_r]/(X_1^p, \ldots, X_r^p)\). The 0th term of \(\alpha_1 e_1 + \cdots + \alpha_r e_r\) is
\[
\alpha_1 X_1 + \cdots + \alpha_r X_r + \text{an element of } (X_1, \ldots, X_r)^2,
\]
and the lemma follows. \(\square\)

It now follows that the \(k\)-linear span of \(e_1, \ldots, e_r\), which is a subspace of the Dieudonné module of \(G_k\), is in fact the whole Dieudonné module (as both are of dimension \(r\)). This gives the following proposition:

**Proposition A.7** The Dieudonné module of \(G_k\) is the \(r\)-dimensional \(k\)-vector space
\[
k e_1 \oplus \cdots \oplus k e_r
\]
with Frobenius and Verschiebung actions given by
\[
F(e_i) = \delta_i e_{i+1}, \quad \text{and}
\]
\[
V(e_i) = \lambda_i^{p^{-1}} e_{i-1}
\]
on the basis elements \(e_i, i \in \mathbb{Z}/r\mathbb{Z}\), which one then extends semi-linearly. \(\square\)

**The Honda system associated to \(G\)**

We need to determine the kernel \(L\) of the composite
\[
M \hookrightarrow CW_k(A_k) \xrightarrow{w} A_k/pA
\]
where \(w\) is defined as follows: for \((a_{-n}) \in CW_k(A_k)\), choose for each \(a_{-n}\) a lift \(\tilde{a}_{-n} \in A\), and define
\[
w((a_{-n})) \overset{\text{def}}{=} \sum_{n \geq 0} p^{-n} \tilde{a}_{-n}^n \text{ mod } pA.
\]
This is well-defined (see Chapter II, section 5.2 of [10]).

Let \( \lambda_j \) be the Teichmüller lift of \( \gamma_j \mod p \). Note that as

\[
X_{i-n}^p = \frac{\omega^{p^{n-1}} \cdot \omega^{p^{n-2}} \cdots \omega}{\gamma_i^{p^{n-1}} \cdot \gamma_i^{p^{n-2}} \cdots \gamma_i^{p^1}} X_i
\]

and

\[
v \left( \omega^{p^{n-1} + \cdots + 1} \right) = \frac{(p^n - 1)}{(p - 1)},
\]

we have

\[
p^{-n} \left( \lambda_{i-1}^{p^n} \cdots \lambda_{i-n}^{p^n} \right) X_{i-n}^p \in pA
\]

for \( n \geq 2 \). It follows that

\[
w(e_i) \cong X_i + p^{-1} \lambda_{i-1} X_{i-1}^p \mod pA
\]

\[
\cong \begin{cases} X_i \mod pA & \text{if } \lambda_{i-1} = 0 \\ 0 \mod pA & \text{if } \lambda_{i-1} \neq 0 \end{cases}
\]

Thus \( L \) contains the subspace of \( M \) spanned by the covectors \( \lambda_{i-1} e_i \). Alternatively, \( L \) contains the subspace generated by \( e_i \) with \( p \) dividing \( \delta_{i-1} \). Since \( FM \) is the \( k \)-span of \( e_i \) with \( p \) not dividing \( \delta_{i-1} \), a dimension count shows that \( L \) is in fact the \( k \)-span of \( \lambda_{i-1} e_i \).
