**Abstract**

*Saccharomonospora viridis* is a thermophilic actinomycete that may have biotechnological applications because of its dye decolorizing activity, though the enzymatic oxidative system responsible for this activity remains elusive. Bioinformatic analysis revealed a DyP-type peroxidase gene in the genome of *S. viridis* DSM 43017 with sequence similarity to peroxidase from dye-decolorizing microbes. This gene, *svidyp*, consists of 1,215 bp encoding a polypeptide of 404 amino acids. The gene encoding *SviDyP* was cloned, heterologously expressed in *Escherichia coli*, and then purified. The recombinant protein could efficiently decolorize several triarylmethane dyes, anthraquinonic and azo dyes under neutral to alkaline conditions. The optimum pH and temperature for *SviDyP* was pH 7.0 and 70°C, respectively. Compared with other DyP-type peroxidases, *SviDyP* was more active at high temperatures, retaining >63% of its maximum activity at 50–80°C. It also showed broad pH adaptability (>35% activity at pH 4.0–9.0) and alkali-tolerance (>80% activity after incubation at pH 5–10 for 1 h at 37°C), and was highly thermostable (>60% activity after incubation at 70°C for 2 h at pH 7.0). *SviDyP* had an accelerated action during the biobleaching of eucalyptus kraft pulp, resulting in a 21.8% reduction in kappa number and an increase of 2.98% (ISO) in brightness. These favorable properties make *SviDyP* a promising enzyme for use in the pulp and paper industries.

**Introduction**

Heme peroxidases, containing prosthetic heme groups, have been divided into two large groups, animal and plant peroxidases [1]. The plant peroxidases are divided into classes I, II, and III, which include fungal (class II) and bacterial peroxidases (class I), according to primary structural homology [2]. Class I peroxidases contain mitochondrial yeast cytochrome c peroxidase, chloroplast and cytosol ascorbate peroxidases, and gene duplicated bacterial peroxidase [2]. Class II enzymes include secretory fungal peroxidases, such as lignin peroxidase [3], manganese peroxidase [4], and versatile peroxidase [5]. Secretory plant peroxidases such as horseradish peroxidase and barley grain peroxidase belong to class III peroxidases. The recently described DyP-type peroxidases (DyPs) (EC 1.11.1.19) superfamily comprises a novel class of heme peroxidases, and are found in both fungi and bacteria [6–14]. DyPs have been classified into four phylogenetically distinct subfamilies, with fungal enzymes belonging to subfamily D and bacterial enzymes constituting subfamilies A–C [15,16]. These enzymes are very promising for use in biotechnological applications. Despite the large number of putative DyP sequences registered in PeroxiBase (http://peroxibase.toulouse.inra.fr/), only a few studies have described the isolation and characterization of peroxidases, including four proteins from actinomycetes [17–21]. However, no DyP-type peroxidase genes have been identified in *Pseudonocardia* to date.

Biobleaching is the bleaching of pulps using ligninolytic microorganisms or enzymes that reduce the amount of chemical bleach required to obtain a desirable brightness of pulps. Some enzymes from fungi and bacteria, such as extracellular xylanase and peroxidase from *Streptomyces* sp [22,23], laccase and manganese peroxidase produced by *Trametes versicolor* [24,25], have been studied for biobleaching of paper pulp and other industrial applications, as they degraded lignin or xylan and decolorized the pulp [26,27]. However, no DyP-type peroxidase enzymes has been characterized and applied in the pulp bleaching field.
In the current work, a novel peroxidase, SvoDyP, related to a putative DyP-type peroxidase enzyme, was isolated, purified, and characterized from *Saccharomonospora viridis*, a pentachlorophenol-degrading thermophilic actinomycete [20]. In addition, the catalytic properties of the enzyme and its application as an enzymatic pretreatment for kraft pulp bleaching were investigated. SvoDyP was an alkali-tolerant thermostable dye-decolorizing peroxidase reported from the *Pseudonocardiaeae* family, which belongs to the genus of *Saccharomonospora*, and it had an accelerated action during the biobleaching of eucalyptus kraft pulp. These favorable properties made SvoDyP a good candidate for application in the pulp and paper industries.

**Materials and Methods**

**Microorganism, culture conditions, and chemicals**

*Saccharomonospora viridis* DSM 43017 was obtained from the China General Microbiological Culture Collection Center, Beijing (reference number CGMCC 4.1324). The strain was cultivated in a shaker flask at 45°C in STS medium (1.0% w/v soy peptone, 1.0% w/v glucose, 0.2% w/v yeast extract, 0.2% w/v NaCl, and 0.2% casin enzymatic hydrolysate, all from Biodee, Beijing, China), adjusted pH to 8.0 with NaOH prior to autoclaving. *Escherichia coli* DH5α and *E. coli* BL21 (Tiangen, Beijing, China) were cultivated in Luria Bertani (LB) medium at 37°C for gene cloning, sequencing, and expression. The pEASY-T3 vector (TransGen, Beijing, China) was used for plasmid gene cloning and sequencing. The plasmid pET-28a (+) (Takara Bio, Otsu, Japan) was used as an expression vector. Manganese peroxidase (MnP), azure B, brilliant green, reactive blue 19, reactive green 19, reactive yellow 2, reactive black 5, reactive red 120, malachite green and crystal violet were purchased from Sigma (St. Louis, MO, USA). All other reagents used were of analytical grade unless otherwise stated.

**Decolorization assay for *S. viridis* on solid medium**

Azure B, which was membrane-filtered with a 0.45-μm cellulose nitrate filter, was mixed with STS medium to give a final concentration of 0.1 g L⁻¹ and used to make agar plates. *S. viridis* was inoculated onto the plates with a sterile spreader. The plates were then incubated at 45°C and their surface appearance was observed daily. A ring of decoloration around the colonies on the blue medium is a qualitative signal of presence or absence of dye-decolorizing enzyme DyP-type peroxidase. The presence of bleaching around colonies on the blue medium indicates the production of the dye-decolorizing enzyme.

**Bioinformatic and phylogenetic analysis and homology modeling**

The whole genome of *S. viridis* DSM 43017 is available from the GenBank database under the accession number NC_013159 [29]. By performing a sequence homology comparison between four well-characterized DyP-type peroxidases from *Shewanella oneidensis* TyrA [13], *Bacteroides thetaiotaomicron* Cd DyP [30], *Rhodococcus jostii* DyPB [31], and *E. coli* YcdB [32], one unannotated DyP-type peroxidase gene (Gene YP_003135694) was identified in the genome of *S. viridis* DSM 43017. The open reading frame, which we tentatively named *svidyp*, showed sequence similarity to peroxidase genes in other dye-decolorizing microbes. The DNA sequence of *svidyp* was analyzed using the software package DNAMAN 6.0 (LYNNON Corporation, Quebec, Canada). Nucleotide and the corresponding deduced amino acid sequence homology searches were carried out using the BLASTn and BLASTp programs, respectively, at the NCBI website (http://www.ncbi.nlm.nih.gov/BLAST/). Multiple sequence alignment was performed by ClustalW [33]. A phylogenetic tree containing the closest homologs of the DyP protein was constructed using MEGA 5.2 with the neighbor-joining algorithm [34]. The deduced tertiary structure of SvoDyP was derived from the amino acid sequence using SWISS-MODEL [35–37].

**Gene cloning, heterologous expression and enzyme purification**

Genomic DNA from *S. viridis* was isolated following overnight growth in STS liquid medium. Cells were harvested by centrifugation (10,000×g, 25°C for 2 min). DNA extraction was then performed using the Bacterial Genomic DNA Extraction Kit V.3.0 (Takara) according to the manufacturer’s instructions. Two primers were designed at the 5’ and 3’ ends of the *svidyp* gene with the following sequences: Svidyp-F: 5’-GGCGAAATTCAT- GAAAGGCGCCGGTTTC-3’ and Svidyp-R: 5’-GGCAAG- CTGTTCAGGCTTCAAAGACGCG-3’, which contained the restriction sites EcoRI and HindIII (underlined), respectively, to enable directional cloning into the pET-28a (+) expression vector. Using these primers, the complete *svidyp* gene was PCR-amplified from *S. viridis* genomic DNA. PCR amplification was performed using Taq DNA polymerase, 10× PCR buffer (Mg²⁺), dNTPs, and pET Toolkit (Takara) under the following conditions: 5 cycles of 94°C for 30 s, 67.3°C for 30 s, and 72°C for 1 min, followed by 30 cycles of 94°C for 30 s, 67.3°C for 30 s, and 72°C for 1 min.

The resulting PCR product was gel-purified, digested with EcoRI and HindIII, and cloned into the corresponding site of the pET28a (+) vector to construct the recombinant plasmid pET28a-svidyp. The plasmid was then transformed into chemically competent *E. coli* BL21 cells. Plasmid DNA from recombinant *E. coli* was isolated using a Plasmid Purification Kit (Takara). DNA concentration was estimated by the absorbance at 260 nm, and DNA integrity was verified by agarose gel electrophoresis. Transformants were identified by PCR analysis and enzymatic digestion, both as described above, and were then confirmed by DNA sequencing using the primers T7 and T7-terminor. Sequencing was carried out by Beijing AuGCT DNA-SYN Biotechnology Co., Beijing, China.

A positive transformant harboring pET28a-svidyp was isolated as a single colony for gene expression. The transformant was cultured overnight at 37°C in 10 ml LB medium containing kanamycin at 50 μg ml⁻¹. The culture was then inoculated into fresh LB medium (1:100 dilutions) containing kanamycin and was grown at 37°C to an OD₆₀₀ of approximately 0.6. Isopropyl-β-D-1-thiogalactopyranoside (IPTG) was then added to a final concentration of 1.0 mM for induction, and the culture was further cultivated at different temperature and time. Following induction with 1.0 mM IPTG at 25°C for 3 h, little activity was detected from the cell lysate, while incubation at 16°C for 12 h the activity in the lysate increased to 9.4 U ml⁻¹. Thus, to effectively induce enzyme expression, induction with 1.0 mM IPTG at 16°C overnight was selected for further production of the recombinant DyP peroxidase. No DyP peroxidase activity was detected from the uninhibited transformant or from the transformant harboring the empty pET-28a (+) vector.

Cultures of induced recombinant *E. coli* (200 ml) were centrifuged (10,000×g, 4°C for 10 min) and the cell pellets were resuspended in 10 ml sodium phosphate buffer (50 mM, pH 8.0). The cell suspension was then lysed by sonication (pulse on: 10 s; pause off: 10 s; power: 130 W; time: 30 min) using a cell ultra sonicator (Sonics® VCX130; Sonics & Materials, CT, USA). Following sonication, the unbroken cells and large debris were removed by centrifugation (12,000×g, 4°C for 20 min) and the
supernatant was collected. Because the enzyme was expressed as a His-tagged protein, the supernatant was loaded onto a Ni-affinity column (Ni-NTA Agarose; Qiagen, Valencia, CA, USA) and eluted with a linear gradient of imidazole (20–250 mM, 25 ml) in sodium phosphate buffer (20 mM phosphate, 300 mM NaCl, pH 8.0), at a flow rate of 1 ml min⁻¹. Fractions displaying DyP-peroxidase activity were combined and applied to a Sephadex-G75 (10×200 mm) column pre-equilibrated with 0.1 M phosphate buffer (pH 7.0) and eluted with the same buffer at a flow rate of 0.5 ml min⁻¹. The purified enzyme with purification yields of 40.3% (Table 1) was stored at −20°C until further characterization. The protein concentration was determined using a Bradford assay [38] using bovine serum albumin as a standard. The purity of SviDyP was verified by sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) analysis on a 12% gel as described previously [39] and by Western blotting analysis using an anti-His 6 tag mouse monoclonal antibody [40].

| Step             | Activity (U) | Protein (mg) | Specific activity (U mg⁻¹) | Yield (%) | Purification fold |
|------------------|--------------|--------------|---------------------------|-----------|------------------|
| Lysate supernatant | 940.0        | 1175         | 0.8                       | 100.0     | 1.0              |
| Ni-NTA agarose   | 437.9        | 39.1         | 11.2                      | 46.6      | 14.0             |

doi:10.1371/journal.pone.0110319.t001

Enzyme characterization

Aliquots of the recombinant SviDyP sample (1 mg ml⁻¹) were put under various conditions to test its stability. The optimal pH for enzyme activity was determined by measuring the reaction rate in buffers covering a pH range of 3.0–12.0. The buffers used were 50 mM citric acid-Na₂HPO₄ (pH 3.0–8.0), 50 mM Tris-HCl (pH 8.0–9.0), and 50 mM glycine-NaOH (pH 9.0–12.0). The pH stability was measured by adding enzyme to buffers ranging from pH 2.0–10.0 at 37°C for 1 h without the substrate solutions, and then, its residual activity was analyzed as described above. The highest activity of the enzyme, treated as above, was defined as 100%. The optimal temperature for enzyme activity was examined over the temperature range of 30–90°C. To estimate the thermal stability, the enzymes were incubated at 50°C, 60°C, 70°C, or 80°C for 0.5, 1, 2, 3, 4, and 5 h without substrate, and the residual enzyme activity was measured with the method as described above. To determine the effect of different metal ions and chemical reagents on the enzyme activity, the enzyme sample (1 mg ml⁻¹) was incubated for 30 min at 37°C and pH 7.0 in 0.05 M Britton–Robinson buffer, supplemented with the following additives respectively (final concentration, 5 mM): SDS, β-mercaptoethanol, ethylenediaminetetraacetic acid (EDTA), ZnCl₂, BaCl₂, MnCl₂, MgCl₂, AlCl₃, CoCl₂, CaCl₂, LiCl, FeCl₃, and FeCl₅. The residual activity was then assayed using the method as described above. And a system without any additives was used as a control.

The Kₘ and Vₘₐₓ values for the purified SviDyP protein were determined by several substrates including reactive blue 19, reactive yellow 2 and brilliant green. Lineweaver-Burk plots were generated from the initial rates obtained at varying substrate concentrations with a constant concentration of the second substrate [42]. Each experiment was repeated three times and each experiment included three replicates.

![Figure 1. Degradation circles produced by Saccharomonospora viridis on azure B screening plates.](doi:10.1371/journal.pone.0110319.g001)
Physico-chemical characterization of kraft pulps and biobleaching with SvDyP

An unbleached eucalyptus kraft pulp was prepared by cooking the dried wood material (provided by JinHai Pulp & Paper Limited Company, Hainan, China) with sulfate process under the following conditions: total alkali, 16.0% (w/v), sulfureted degree 25% (w/v), liquid ratio 1:6, and a cooking temperature of 160°C for 2 h. The optimization of enzyme dose and reaction time for biobleaching was carried out by treating pulp with varying doses of DyP-type peroxidase, ranging from 0–6.0 U g⁻¹ dry pulp, for various time intervals up to 6 h. Pulp properties were investigated at regular intervals. Enzyme-treated and untreated pulp samples at 10% pulp consistency were incubated at 65°C with SvDyP (5 milligram protein per gram dried pulp, equivalently enzyme dosage as 3 U g⁻¹) which was in terms of enzyme activity towards brilliant green) in 50 mM citric acid-Na₂HPO₄ buffer (pH 7.0) for 2 h, whereas the biobleaching by MnP with 0.5 mM MnSO₄ was performed at 25°C in pH 4.5 for 2 h as the positive control. 0.1 mM H₂O₂ was added in all the assays. During the bleaching treatment, kneading the pulp mixture every 15 min was needed in order to make sure all ingredients can mix well. After the enzyme bleaching, pulps were thoroughly washed with deionized water to remove soluble reducing sugars and any free soluble residual lignin, and then made into pieces of paper by the sheet forming machine. Pulp sheet preparation was conducted as described in the paper [43]. Degree of brightness of pulp according to ISO (International Standards Organization) was measured on a YQ-Z-48A (Qingtong, Hangzhou, China) brightness color tester. Pulp kappa number was determined by using TAPPI useful method T236 (Technical Association of the Pulp and Paper Industry, Atlanta, Ga.). All reported data are averages of experiments performed in at least six replicates.

Scanning electron microscopy

Samples of pulp fibers were processed for scanning electron microscopy (SEM). Paper pulp samples were formed into hand sheets using a Buchner funnel. Small pieces of fiber were vacuum dried in the presence of P₂O₅, placed on the stubs and mounted with silver tape, and then sputter coated with gold using fine coat. The samples were examined at 5.0 kV under a scanning electron microscope (Hitachi S-4300, Ibaraki, Japan) at various magnifications.
Results

Decolorization assay for S. viridis on solid medium

Some bleaching laps were observed on STS medium mixed with 0.1 g l⁻¹ azure B around colonies of S. viridis (Fig. 1), which were produced after incubating at 45°C for 3 days, indicating the presence of a dye-decolorizing enzyme. This indicated one or more extracellular dye-decolorizing enzymes produced in the cultivating process of S. viridis. 

Figure 3. Multiple sequence alignment of the SviDyP amino acid sequence with other members of DyP-type peroxidases family. The sequence alignments were performed using ClustalW (Thompson et al. 1994). Perfect match residues are displayed in white on black shade. The unique GXXDG motif is boxed. The conserved residues of the active site are indicated by asterisks. Residues indicated by triangles are residuals important for coordinating the heme at the active site.

doi:10.1371/journal.pone.0110319.g003
SviDyP is a member of the DyP-type family enzymes

To isolate the gene encoding the DyP-type peroxidase from *S. viridis* DSM 43017, two specific primers, Svidyp-F and Svidyp-R, were designed. PCR amplification of the DyP-peroxidase gene (GenBank under accession number KF444221) of *S. viridis* generated a DNA fragment of 1215 bp, which encoded a polypeptide of 404 amino acids with a predicted molecular mass of 44.5 kDa and a deduced isoelectric point of 5.17. Sequence analysis showed that overall G+C content of the svidyp gene was 70.1%.

The deduced amino acid sequence of SviDyP showed 36% amino acids identity with *Bacillus subtilis* BsDyP [15] and *R. jostii* DyPB [31], 33% *E. coli* YcdB [32], 27% to *S. oneidensis* TyrA [13] and 21% to *B. thetaiotaomicron* BtDyP [30]. Twenty typical and hotspot DyPs proteins, such as *Thermobifida fusca* TfuDyP [21], *S. oneidensis* TyrA [13], *B. subtilis* BsDyP [15], and *R. jostii* DyPB [31], were used to phylogenetic analysis. Phylogenetic trees and multiple sequence alignments showed that SviDyP was most closely related to *Mycobacterium* sp. MySpDyP, *Thermobifida fusca* TfuDyP, *Rhodococcus jostii* DyPA, *Escherichia coli* EfeB/YcdB, *Bacillus subtilis* BsDyP [15] and the putative uncharacterized protein Sco3963 from *Streptomyces coelicolor* A3 (2), all of which belong to subfamily A (Fig 2). Therefore the enzyme SviDyP was grouped into subfamily A, and typical motifs, such as conserved GXXDG motif and some conserved amino acid residues (D223, N227, R328, H313, E342, D371), were found in DyP-type

Table 2. Enzymatic activity of purified SviDyP towards various dyes.

| Substrate          | $\lambda_{max}$ (nm)/$e$ at $\lambda_{max}$ | pH | Temp (°C) | Initial concn (µM) | Specificity activity (U mg$^{-1}$) | Relative activity (%) |

peroxidases (Fig 3). The model structure of SviDyP showed two domains consisting of a four-stranded antiparallel \( \beta \)-sheet and peripheral \( \alpha \)-helices which is typical in the DyP-type family (Figure S1).

**Heterologous expression and purification of SviDyP**

The svidyp gene was successfully cloned into the pET28a vector and expressed in *E. coli* BL21, forming the recombinant clone *E. coli* BL21/pET28a-svidyp, with the expression of His-tagged protein. The purified SviDyP protein, as verified by SDS-PAGE analysis and Western Blot analysis (Fig. 4a) by anti-6xHis antibody, was about 45 kDa, consistent with the theoretical value of 44.5 kDa.

**Biochemical and spectroscopic characterization of SviDyP**

The UV-visible spectrum of SviDyP at resting state showed the main Soret band at 406 nm and two charge transfer bands at 503 nm and 636 nm (Fig. 4b), as well as a Reinheitszahl ratio \( (A_{406}/A_{280}) \) of 1.7. The molar absorption coefficient of SviDyP, \( \varepsilon_{406} \), was 97,000 M\(^{-1}\) cm\(^{-1}\), similar to values found for other peroxidases and DyPs [8,44].

The recombinant enzyme expressed and purified from *E. coli* BL21 was then biochemically characterized. The controls of without \( \text{H}_2\text{O}_2 \) and/or without enzyme were without significant statistical difference. Substrate specificity of the enzyme was determined by using a subset of well-known peroxidase substrates and anthraquinone and azo dyes (Table 2). The enzyme displayed maximal activity towards the anthraquinone dye reactive blue 19 (1.29 U mg\(^{-1}\)), the azo dyes reactive green 19, reactive yellow 2, reactive black 5, and reactive red 120 (1.32, 4.86, 0.96 and 0.69 U mg\(^{-1}\), respectively), and the triarylmethane dyes brilliant green, malachite green, and crystal violet (12.24, 8.4 and 4.11 U mg\(^{-1}\), respectively). SviDyP was able to act on veratryl alcohol (0.03 U mg\(^{-1}\)), but not very efficiently (Table 2), and also showed activity towards azure B (1.62 U mg\(^{-1}\)), a methylated thiazine dye that is a good substrate for lignin peroxidase [45]. Additionally, SviDyP showed a modest activity towards 2,6 - dimethoxyphenol (0.06 U mg\(^{-1}\)) which is a typical methoxylated phenol substrate for plant peroxidases. From the above, it is true that SviDyP displays (DyP-type) peroxidase activity.

To study the behavior of the enzyme under various pH and temperature conditions, brilliant green was used as the substrate.
The optimal pH of SviDyP at 60°C was 7.0. It had broad pH adaptability (>35% activity at pH 4.0–9.0) and retained over 62% of the peak activity at pH 6.0–8.0 (Fig. 5a). SviDyP was highly alkali-tolerant, retaining at least 80% of its initial activity after incubation at 37°C for 1 h in buffers ranging from pH 5.0–10.0 (Fig. 5b). The optimal temperature for SviDyP activity was 70°C, at pH 7.0 (Fig. 5c). SviDyP was highly thermostable, retaining at least 63% of its maximum activity at 50–80°C, and approximately 95% at 80°C. The thermostability of the enzyme was investigated for a period of 5 h at temperatures ranging from 50–80°C (Fig. 5d). It was observed that SviDyP maintained approximately 60% of maximal activity at 60°C and 70°C for at least 3 h and 2 h, respectively.

The effect of different metal ions and metal chelating agents on the enzymatic activity was also assayed, using brilliant green as the substrate (Table 3). The activity of control without any additives was defined as 100%. The activity of the enzyme was not affected (residual activity, >80%) by the presence of 5 mM final concentration of 

| Reagent                | Residual activity (%) 5 mM |

doi:10.1371/journal.pone.0110319.t003

The kinetic analysis of purified SviDyP corroborated the Michaelis-Menten behavior of the enzyme, with a \( V_{max} \) of 38.46 ± 0.98 \( \mu \text{mol} \text{ min}^{-1} \) and a \( K_m \) of 58.87 ± 4.7 \( \mu \text{mol} \text{ L}^{-1} \) for brilliant green, a \( V_{max} \) of 3.7 ± 0.41 \( \mu \text{mol} \text{ min}^{-1} \) and a \( K_m \) of 187.2 ± 16.6 \( \mu \text{mol} \text{ L}^{-1} \) for reactive yellow 2, and a \( V_{max} \) of 2.2 ± 0.26 \( \mu \text{mol} \text{ min}^{-1} \) and a \( K_m \) of 210.2 ± 16.5 \( \mu \text{mol} \text{ L}^{-1} \) for reactive blue 19. Such kinetic behavior strongly suggested that the cloned enzyme might be a DyP-type peroxidase.

Enzyme effects on pulp bleaching

Enzyme effects on pulp bleaching were reflected by measuring the physicochemical properties of paper pulp bio-bleached by enzymic preparations. The unbleached/raw eucalyptus kraft pulp had a kappa number of 11.0 and a brightness of 33.6% (ISO) [43]. With the increase of enzyme dosage and reaction time, the pulp brightness was increased and kappa number was reduced gradually, and then they keep invariant (Figure S2). When the enzyme dosage was 3 U g<sup>−1</sup> (Figure S2a, b) and the reaction time was 2 h (Figure S2c, d), the pulp brightness reached the maximum, and pulp kappa number reached the lowest value. Therefore, the choice of 3 U g<sup>−1</sup> as an optimal enzyme dosage and 2 h as an optimal reaction time were the best condition of SviDyP biobleaching kraft pulp (Figure S2). The experiments of pulp bleaching by recombinant protein SviDyP showed that enzyme treatment to improve the brightness of the pulp 2.98%, pulp kappa number reduced 21.8% compared with control (Table 4), indicating that the enzyme treatment can significantly improve the brightness of the pulp, but reduce kappa value will help subsequent bleaching. Application of MnP in the pulp bleaching experiment showed that MnP reduced the specific pulp kappa number by 31.8%, and increased the whiteness of pulp by 5.90% at pH 4.5, 25°C (Table 4), whereas it reduced the specific pulp kappa number by 24.8% and increased the whiteness of pulp by 3.26% at pH 7, 65°C.

To study the effect of the enzyme on fiber surface morphology in SviDyP-bleached pulp, eucalyptus kraft pulp fiber morphology and surface changes were observed by SEM (Fig. 6). Without any enzymatic bleaching, eucalyptus kraft pulp fibers were stiff, and the surface structure was relatively smooth with no damage or cracks (Fig. 6a). The surface morphology of fibers treated with MnP is shown in Fig. 6b and the fibers treated with DyP-type peroxidase from <i>S. viridis</i> are shown in Fig. 6c and 6d. The pulp fiber surface treated with DyP-type peroxidase from <i>S. viridis</i> appeared rough and wrinkled and showed signs of slight fissures as well as that treated with MnP. There were also many holes in the fiber surface.

Table 3. Effect of various agents on SviDyP activity.

surface fibers, and fibers began to increase in flexibility (Fig. 6b, 6c and 6d). These representative images show the obvious cracks, grooves and spalling in the surface of the fibers, with some fibers having holes with an aperture diameter of 7 μm, which increases fiber flexibility.

**Discussion**

The pentachlorophenol-degrading thermophilic actinomycete *S. viridis* and its extracellular enzymes offer great potential for different biotechnological applications. Both a crude extracellular xylanase [46] and a purified xylanase [47], apparently in the absence of cellulase or endoglucanase activity, have been described in *S. viridis*, and may represent a potential new enzyme source for use in pulp bleaching preparations. In the current study, we reported the cloning, expression, purification, characterization, and pulp biobleaching application of an alkali-tolerant thermostable peroxidase *SviDyP* from *S. viridis* DSM 43017.

Bioinformatic analysis revealed one unannotated DyP-type peroxidase gene in the genome of *S. viridis* DSM 43017 that had sequence similarity with other DyPs at the primary structure level showing the characteristic conserved residues in the heme-binding site and GXXDG motif [12]. Based on the phylogenetic analysis, *SviDyP* belongs to subfamily A of DyPs. Compared with other DyPs from subfamily A, the purified recombinant *SviDyP*, appeared remarkably broad range substrate specificity of which could degrade various dyes, such as triarylmethane dyes, anthraquinonic and azo dyes, at different levels, much better than some enzymes grouped into subfamily A, for example, YcdB [48], TiuDyP [21]. The enzyme could efficiently decolorize triarylmethane dyes to other triarylmethane dye-degrading microorganisms [49,50], and was more active towards crystal violet [51,52] and malachite green [51,53,54]. *SviDyP* also showed the ability to degrade anthraquinonic and azo dyes under neutral to alkaline conditions. Hence, such a multifunctional peroxidase with wide substrate specificity was likely capable of decolorizing other, currently unidentified, xenobiotics. Which suggested that *SviDyP* might be applied directly to solve various environmental and industrial problems, such as the disposal of dye wastewater and pulp biobleaching rather than the DyPs [8,9] which usually worked under acid condition.

To further explore the feasibility of using *SviDyP* in biotechnological applications, enzyme stability was evaluated at different pH levels and temperatures. More luckily, *SviDyP* was very stable over a pH range of 5–10, and retained more than 80% of the maximum residual activity. It also displayed high thermal stability, maintaining 63% of residual activity after 4 h of incubation at 50°C, and more than 60% of residual activity after 2 h of incubation at 60°C. *SviDyP* showed greater stability than DyP from *Anabaena* sp. [16], which had an activity loss of 90% following 3 h incubation at 50°C. Stability studies showed that *SviDyP* exhibited a high degree of stability under alkaline pH and high temperatures. This ability to work efficiently under such high pH environments was a characteristic that distinguishes DyPs from most peroxidases [55]. These findings enriched DyP-type peroxidases family’s information databases and laid the foundation for the study of structure, function and reaction mechanisms of *SviDyP*.

Concerning the influence factors of using *SviDyP* in the further bleaching industrial application, the activation/inactivation effect of the different metal ions and chemical reagents on the enzyme activity was studied. Interestingly, addition of EDTA did not inhibit the enzyme, which suggested that there are no essential

---

**Figure 6. Morphology of bleached pulp fiber surface.** Scanning electron micrograph of unbleached (control) eucalyptus kraft pulp (a). ions in the reaction mixture for the enzyme activity [7,8]. Al³⁺ had similar activating effect between SviDyP and *Pseudomonas aeruginosa* DyPPa [7], probably through promoting the oxidation. SDS resulted in the complete activity loss of SviDyP and DyPPs [7], which demonstrated that SDS could be an important DyP inhibitor. β-mercaptoethanol highly boosted the enzymatic activity presumably by counteracting the oxidation effects of the S-S linkage between cysteine residues [56,57].

The applicability of SviDyP in biobleaching of Kraft pulp, a process of high biotechnological interest, was examined by prebleaching eucalyptus Kraft pulp with the purified SviDyP enzyme. Under 65°C, pH 7.0, SviDyP enzyme had positive effects on the pulp bleaching process as well as MnP, while the biobleaching effects of MnP at 25°C, pH 4.5, were better than SviDyP at 65°C, pH 7.0. These data suggest a slightly temperature and pH adjustment were needed in the usage of SviDyP in bleaching pulp. Furthermore, the SEM studies revealed that the existence of local fracture phenomena and the large area of the trench structure containing holes would result in the fiber structure becoming loose, and the internal structure of lignin being fully exposed. This may help the bleaching agent permeate better, and perfects delignification, which will happen later. Thereby, this breakdown in structure means that much less bleaching agent was needed, and less poisoned organochlorine was produced (data not shown).

In addition, the prepared SviDyP peroxidase had hardly some cellulase activity (data not shown), thereby it prevented reduction of fiber strength and viscosity of thick liquid. The enzyme did show significant heat and alkali resistance, and could directly and effectively attack lignin. Therefore, SviDyP is applicable to the process of pre-bleaching paper pulp for industrial production, and shows excellent bleaching effects. With its wide substrate specificities and thermophilic capabilities, SviDyP peroxidase is a promising enzyme with considerable biotechnological and commercial potential, especially in the pulp and paper industry.
