Abstract

Blue green algae also called cyanobacteria are considered to be the photosynthetic prokaryotes. Their similarities with both higher plants and simple bacteria have made them ideal model systems for intensive research in varied spheres of biology. Their role in nitrogen fixation is well known but their role as prebiotics to support the growth of probiotic bacteria is an upcoming field of study. Prebiotics includes indigestible carbohydrates mainly oligosaccharides that benefit the host organism by selectively stimulating the growth or activity of one or a limited number of probiotic bacteria in the colon. Spirulina, a cyanobacterium is a photoautotrophic microorganism, widely distributed in nature and is consumed as human food supplement for centuries because of its best known nutritional value. It contains 78% proteins, vitamins, 4-7% lipids, minerals, carbohydrates and some natural pigments. Due to the presence of these phytonutrients, it has corrective properties against several diseases like cancer, hypertension, hypercholesterolemia, diabetes, anaemia etc. Research studies have reported that the extracellular products produced by Spirulina platensis significantly promotes the growth of lactic acid bacteria such as Lactococcus lactis, Streptococcus thermophiles, Lactobacillus casei, Lactobacillus acidophilus, and Lactobacillus bulgaricus. The present paper would focus on the prebiotic efficiency of certain blue green algae on probiotic microorganisms.

Keywords: Prebiotic; Probiotic Bacteria; Blue-green Algae; Phytonutrients

Introduction

According to definition, probiotics are defined as selected, viable, microbial dietary supplements that when introduced in sufficient quantities, beneficially affect human organism through their effects in the intestinal tract [1,2]. There are large number of probiotics currently available in fermented dairy products like yoghurt, cheese, curd, ice-cream etc. All these products contain diverse group of microorganisms preferably belonging to lactic acid bacteria. Some of them are natural inhabitants of the intestinal tract and others as fermentative lactic acid bacteria used in the food industry for imparting improved flavor, texture and processing and preservative properties. Some species are administered to humans as live microbial supplements, which positively influence our health mainly by improving the composition of intestinal microbiota. For this reason, they are called probiotics.

Some selected strains of Lactobacillus, Bifidobacterium, Streptococcus, Lactococcus and Saccharomyces have been promoted in food products because of their reputed health benefits [3]. The probiotic effect of these microorganisms include prevention of constipation in elderly people, preventing diarrhea, stimulation of immune system [4], lactose intolerance, reduction in cholesterol levels in blood and prevention of cancer [5]. Apart from these therapeutic benefits, probiotics also offer protection against many opportunistic human pathogens [6,7]. Ingestion of probiotic bacteria may actually improve many of the host’s physiological processes. These include a reduction in mutagenic enzymes such as β-glucuronidase, nitroreductase, and choloylglycine hydrolase [8].

To observe a positive health effect of their consumption, a minimum level of live microorganisms is required. This level, depend upon the strains used and the required health effect ranges between $10^8$ and $10^{11}$ CFU/gl. It has corrective properties against several diseases like cancer [9]. Prebiotics are the foods for probiotic bacteria. They are defined as non-digestible or low-digestible food ingredients that benefit the host organism by selectively stimulating the growth or activity of one or a limited number of probiotic bacteria in the colon [10]. This role is played by fermentable carbohydrates, which are not digested or poorly digested in the small intestine and stimulate, preferentially, the growth of bifidobacteria and some Gram-positive bacteria, belonging to the probiotic bacteria administered to humans. Complex carbohydrates pass through the small intestine to the lower gut where they become available for some colonic bacteria but are not utilized by the majority of the bacteria present in the colon. Lactulose, galacto-oligosaccharides, fructo-oligosaccharides, inulin and its hydrolysates, maltot-oligosaccharides, and resistant starch are prebiotics commonly used in human nutrition. The main end products of carbohydrate metabolism are short-chained fatty acids, namely acetate, butyrate and propionate, which are further used by the host organism as an energy source.

The most common oligosaccharides are inulin and its hydrolysates and oligofructans. They can be found in chicory, topinambur, onion, garlic, asparagus, artichoke, leek, bananas, tomatoes and many other plants. Prebiotic oligosaccharides can be produced in three different ways: by extraction from plant materials, microbiological synthesis or enzymatic synthesis,
and enzymatic hydrolysis of polysaccharides [11]. In practice, combined mixtures of probiotics and prebiotics are often used because their synergistic effects are conferred on food products. For this reason, such mixtures are called symbiotics.

The production of prebiotics at industrial scale faces several challenges, including the use of novel techniques and economical sources, and the low-cost production. Most oligosaccharides with prebiotic status are normally obtained by enzymatic treatment of cheap raw materials such as sucrose, lactose and plant derivatives [12]. The amount and nature of oligosaccharides formed depend upon several factors such as the enzyme source, the concentration and nature of the substrate and the reaction conditions. Nevertheless, the current processes used to obtain oligosaccharides have very low yields, thus increasing the production cost [13]. Therefore, prebiotics from marine and freshwater algae are an attractive alternative source for promoting the growth of Lactobacillus and Bifidobacterium spp., which are the widely studied probiotic strains of lactic acid bacteria.

Cyanobacteria as Prebiotics

Macroalgae are regarded as a rich source of sulfated polysaccharides, and the particular types of polysaccharides varied depending on the taxonomic group. The key function of these relatively high molecular weight polysaccharides is that they are rich in hydroxyl (OH) groups, making them hydrophilic. They are known to establish intra-chain H-bond networks, making them rigid and suitable as thickeners. The regularity of their structures also promotes their interaction with external ions and inter-chain H-bonding (e.g. gelation) [14]. Different carbohydrates including ulvans, carrageenan, or alginites are extracted from macroalgae and are widely used in the food and pharmaceutical industries as functional ingredients.

Spirulina platensis (S. platensis) is a planktonic, filamentous blue-green algae found in many freshwater environments including ponds, lakes, and rivers. *Spirulina platensis* contains about 13.6% carbohydrates; some of which are glucose, rhamnose, mannose, xylose and galactose. *Spirulina platensis* biomass is known to stimulate bacterial growth, and studies performed indicated that the algae consumes nitrogen from the growth medium and releases extracellular carbohydrates and other growth substances which, may be responsible for stimulating growth of *Lactobacilli* (and other lactic acid-producing strains) [15].

Chlorella species

*Chlorella* species is unicellular green algae of Chlorophyta found in both fresh and marine water. Polysaccharide complexes from *Chlorella pyrenoidosa* and possibly, *Chlorella ellipsoidea*, contain glucose in combination with any of the following sugars like galactose, rhamnose, mannose, arabinose, N-acetylgalactosamid and N-acetylgalactosamine [18]. An acidic polysaccharide was isolated from *Chlorella pyrenoidosa* containing mostly rhamnose (52%) with both arabinose and galactose in about equal amounts (12 and 13%, respectively). These complexes are believed to have immuno-stimulating properties, inhibiting the proliferation of Listeria monocyctogenes and Candida albicans [19, 20].

Tetraselmis species

*Tetraselmis* is a sizeable genus (more than 50 species) of green flagellates. Most species are known from inshore marine environments, tide pools in particular, but a few freshwater species are also known [21]. The cell walls (theca) of *Tetraselmis spp.* consist mainly of acidic polysaccharides (82% of dry weight) [22].

Dunaliella salina

*Dunaliella salina* (*D. salina*) is a unique unicellular species of Chlorophyta with no cell wall found in saline environments [23]. This alga has been reported to produce extracellular polysaccharides that are known to have immuno-stimulant, anti-viral and anti-tumor activities [24].
Prebiotic Efficiency of Blue Green Algae on Probiotics Microorganisms

Scenedesmus species

*Scenedesmus spp.* are ubiquitous organisms and are frequently dominant in freshwater lakes and rivers. They are well-known for their nutritional value and considered as potential food additives [25]. *Scenedesmus spp.* has also been used for producing lipid and carbohydrate suitable for making liquid biofuels [26]. Colony formation in algae is linked to polysaccharide production however polysaccharide from these algae is limited [27].

Chlorococum species

The marine green alga *Chlorococcus* is a unicellular spherical strain with cells of diameter about 10μm belonging to Chlorococcaceae family [28]. It is of interest due its tolerance to high CO₂ concentrations and the fact that it can grow to high cell density [29], just like all other microalgae, it can produce value added by-products that can enable their processes more economical. Some of the examples include their use in medicinal and pharmaceutical industry as well as health drinks for their immune-stimulatory, antioxidant, antiviral, and anticancer activities [30].

Cylindrosperum species

*Cylindrosperum* usually inhabits soft, acidic freshwater lakes and is one of the filamentous, heterocystous and non-branched cyanobacteria, classified traditionally in Nostocaceae family. The filaments form fine or compact benthic mats or colonies and may be epiphytic or metaphytic [31]. *Cylindrosperum spp.* are employed in agriculture as biofertilizers and soil conditioners. They are capable of fixing atmospheric nitrogen and are effectively used as biofertilizers its application is useful for the reclamation of soils [32].

Synbiotic Effect of Algal Oligosaccharides

A combination of probiotic(s) and prebiotic(s) constitutes a synbiotic, which can stimulate and increase the survival of probiotic and autochthonous-specific strains in the intestinal tract [33]. The combination of a probiotic of plant material for example; inulin and a prebiotic in one product has shown to confer benefits beyond those of either prebiotic or probiotic [2]. Probiotic and prebiotic treatment has been shown to be a promising therapy to maintain and repair the intestinal environment. Consumption of healthy live microorganisms (lactic acid bacteria) with prebiotics such as inulin, galacto-oligosaccharide and oligo-fructose to mention a few, may enhance healthy colonic microbiota composition. This combination might improve the survival of the bacteria crossing the upper part of the GIT, thereby boosting their effects in the large bowel [34].

The various research studies have shown that aqueous algal extracts from *S. platensis*, *Chlorococcus*, *D. salina*, *S. magnus*, *Chlorella* algal extracts are potential sources for prebiotic production. *Spirulina platensis* extract was regarded as the best algal source for prebiotic as it had a greater stimulatory effect on the growth of all three probiotic bacteria (*L. lactis, B. longum* and *L. bulgaricus*). Xylose and galactose characterized by HPLC in algal extracts make up oligosaccharides that function as prebiotic compounds for stimulation of probiotic bacteria [33]. Thus there is a great scope for successful production of prebiotics from algal sources.
