**Abstract**

The efficiency of boric acid, borax and imidacloprid is evaluated for inhibition of adult house fly emergence (IC₅₀ values) as dry and liquid baits. In the two cases, imidacloprid has the greatest fatal effect at both IC₅₀ and IC₉₀ levels followed by boric acid and then borax. In the liquid formulation, IC₅₀ and IC₉₀ values are (0.083 and 2.6%), (0.19 and 2.48%) and (2.6 and 16.9%) for three tested compounds respectively. The relative efficiency for imidacloprid and boric acid compared to borax (the least potent one), imidacloprid and boric acid achieved 31.3 and 13.7 times more suppression of adult emergence than borax. In the solid formulation, IC₅₀ and IC₉₀ values are (0.083 - 0.67%) followed by boric acid (3.7-11.6%) and borax (3.74-21.1%) respectively. It’s clear that imidacloprid 68.8 times and borax 1.5 times as toxic as borax. Reasons for differences in manifestation of mortality and possibilities for practical application are discussed. We conclude that the efficiency of tested compounds as liquid baits is higher than as dry baits.

**Keywords:** Efficiency; Boric acid; Borax; Imidacloprid; Housefly

**Introduction**

The common house fly (*Diptera: Muscidae*) continues to be a nuisance and acts as an important mechanical vector of pathogenic organism. Flies feeds and breeds in manure, excrement, garbage, sewage sludge and fermenting crop wastes and other sources of filth, where they can pick up and transport various diseases agents amongst humans and animals. Medically important pathogens such as bacteria, fungi, viruses, warm protozoa and nematodes were isolated on the house fly surface [1-5]. Flies have rapid, prolific breeding habits high, mobility and short life cycle, it a difficult control. In order to break the life cycle, control measures should be direct against larvae and adult flies. The traditional and the most extensive control technique used for the suppression of house fly population has been the application of residual contact insecticides. As a result of continuous use of insecticides to control flies, the problem of resistance began to appear. House fly insecticides resistance is global problem [6-9] and has specifically been documented in Egypt [10-14]. Historically house flies have shown great propensity to develop insecticide resistance, new methods need to be evaluated to prevent future control failures. Toxic baits have been an important tool in fly management program. Localized toxic target technique, like insecticide application through baits is advantageous as not only decrease the risk of resistance developing in flies but also greatly reduce the amount of insecticides released into environment. Also, conservation of predators and parasites of immature stages of house flies [15,16]. Recently, a new promising strategy based on attract and kill for controlling vectors of diseases called attractive toxic sugar bait (ATSB) method. Introduction of ATSB on bait stations have been successful against vectors of diseases in different parts of the world [17-19]. In this method, vectors are attracted to a surface or vegetation that applied with ATSB containing toxins such as organic compound (e.g., imidacloprid, azamethiphos, fipronil, methyamyl and chloropyrifos) or inorganic compound (Boron compounds). Neonicotinoid insecticides are the new class of insecticides and have higher selectivity factor for insect versus mammals [20,21]. Imidacloprid is an insecticide belonging to chloronicotinoid class compound. It is effective against a wide range of nuisance and public hygiene insect species [22-26]. Insecticides containing boron have a long history of use in pest control [27]. Boron-containing compound, especially boric acid and its sodium salts (e.g., borax, disodium octaborate and sodium metaborate) have been use routinely for fly control before the advent of chlorinated hydrocarbons and DDT, but it was used primarily as larvicid [28]. Boric acid and borax still remains a very safe and useful chemical acting as a contact insecticide and as stomach poison. Recent research had demonstrated efficacy of boron compound against several household pests [29-36]. Sub lethal doses concentrations of insecticides have been shown to cause latent toxicity [37]. Sub lethal effect is expressed as physiological impact on individuals that survive an exposure to an insecticide [38], for example, in changes of biological parameter, longevity, reproduction, fertility of eggs, puation, adult emergence and development in the life history. Several biological effects are reported in the literature due to the use of sub lethal doses concentrations of insecticides [39-42]. Insecticide mixtures have been proposed as important tools for resistance management in different insect pests. Insecticide mixtures could enhance the toxicity of insecticides in different resistant insects [43-47].

The present study was carried out with three objectives:

- To evaluate the toxicity of sugar baits containing boric acid, borax and imidacloprid against larvae and adult of house fly in liquid and dry formulations
- Latent effects resulted from treated larvae and adults with sub lethal concentrations of ATSB
- Efficacy of combination of imidacloprid with boric acid or borax.

Materials and Methods

Insecticides tested

The insecticides tested included two inorganic compounds (boric acid and borax) and one organic compound (imidacloprid).

Inorganic compound

a) Boric acid:

- **Common name:** Boric acid (Orthoboric acid, Boracic acid, Borofax)
- **Chemical name:** Trihydroxidoboron
- **Chemical formula:** BH$_3$O$_3$ or B(OH)$_3$

b) Borax.

- **Common name:** Borax (Sodium borate, Sodium tetraborate, Disodium tetraborate).
- **Chemical name:** Sodium tetraborate decahydrate
- **Chemical formula:** Na$_2$B$_4$O$_7$. 10H$_2$O

Organic compound (Imidacloprid)

- **Common name:** Imidacloprid (Admire, confidor, Pravado)
- **Chemical name:** 1-(6-chloro-3-pyridylmethyl)-N-nitromidalzolidin-2-ylidenamine.
- **Chemical formula:** C$_9$H$_{10}$CIN$_5$O$_2$

Tested insect

**House fly, Musca domestica**

Family: Muscidae

Order: Diptera

Adult house flies were collected from garbage dumps, Giza Governorate by insect’s net as a field strain and transferred to the laboratory. Adults were maintained in cubical cage, 35 cm in each direction. It is constructed of wood frame, covered with Iron network on top and sides. The bottom is made of a movable metallic sheet to facilitate cleaning. The front side was provided with a wooden frame with muslin cloth sleeve, which was used for handling the insects, and introducing the food. The adult flies were provided with cotton ball saturated with 10% milk solution containing 2% sugar held in petri dish for feeding and served as a medium for oviposition. The food was replaced every day.

Eggs were remove from cotton ball and placed on the top of rearing medium in glass jar. The jar top was covered with muslin square held in place by two rubber bands. The breeding medium of larvae consists of wheat bran, yeast, powder milk and water, in the ratios of 20:1:2:20 parts respectively [48-51].

Different larvae instars were reared on larval medium until pupation. The late third instar larvae migrate to the upper layer of the medium to pupate. The dry top layer of media in each jar was removed and transferred to a basin. A stream of air was used for separating the pupae from dried medium. The pupae were transferred to adult breeding cages for emergence. The population was reared at 27 ± 1°C and 65 ± 5% relative humidity (RH).

Preparation of Attractive Toxic Sugar Baits (ATSB)

**ATSB solution:** Sugar bait solution was made by adding sugar to water at rate of 10%. Boric acid, borax was added directly to sugar solution 10% to obtain serials concentrations. Imidacloprid was dissolve in alcohol before added to sugar solution 10%

**ATSB dry:** The baits were prepared by mechanically mixing technical insecticide with granulated sugar or prepared by mixing alcohol solutions of technical grad insecticides with granulated sugar and allow the solvent to evaporate. Tested application treatments:

- For imidacloprid (0.02 - 0.32%)
- For boric acid (0.125 - 4%)
- For borax (1-12%)

Another experiment for ATSB dry formulation, the range of concentration tested was as follows:

- For imidacloprid, (2 to 12%) for boric acid and (2 to 16%) for borax. Small plastic cups were filled with five grams of larval medium. Twenty-five third instar larvae were used per treatment. Control groups provided with untreated medium (rearing medium plus sugar solution 10% or granules sugar). Each insecticides concentration and sugar control for each insecticide were replicated four times. Mortality of larvae was observed daily until pupation. The number of pupae and adults emerging were recorded.

Results and Discussion

Effects of ATSB on the development of house fly larvae

**ATSB as liquid baits:** The development of third instar larvae of house fly Musca domestica was affected by imidacloprid, boric acid and borax treatment of larval medium as ATSB liquid baits (Tables 1-3 and Figures 1-3), and the effects were concentration dependent.

Table 2: Effect of boric acid on the development of the house fly in a treated medium containing third instar larvae (liquid baits).
From data shown in Table 1 and Figure 4, it clears that the pupation rate was reduce at imidacloprid concentration as 0.32%, only 18% of treated larvae reached the pupal state. Additional 0.92% reduction in emergence of adult was observed for the same treatment.

Observation of the effect of boric acid (Table 2 and Figure 5) on the development of larvae showed that application of 4% resulting in 65% larval mortality and 35% pupation. This treatment prevented all exclusion of flies.

Borax also had some effects on the larval-to-pupal stage of development; however, compared with that of imidacloprid and boric acid, the effect of borax was relatively weak. The effect of borax on larvae to pupae development at high concentration of 12%, the formulation of pupae was 30%. Similarly, a reduction in adult emergence from the pupal stage was also observed; borax achieved 92% suppression of adult emergence (Table 3 and Figure 6). The efficiency of tested compounds is evaluated for inhibition of adult emergence (IC values). Data in Table 4 and Figure 7 revealed that, imidacloprid has the greatest fatal effect at both IC50 and IC90 levels followed by boric acid and then borax. This was represented by IC50 and IC90 values, (0.083 and 2.48%) and (2.6 and 16.9%) for three tested compounds respectively. The relative efficiency for imidacloprid and boric acid compared to borax (the least potent one), imidacloprid and boric acid achieved 31.3 and 13.7 times more suppression of adult emergence than borax (Figure 7).

**ATSB as dry baits:** Data on the effectiveness of dry formulation baits of tested compounds on development of third instar larvae of house fly are shown in Tables 5-7 there was a concentration dependent relationship in the rate of pupation and adult emergence with three compounds.

The mortality of larvae reached to 73% (27% pupation) when the larvae were reared in media containing 0.38% imidacloprid. Also, the number of flies was reduced by 85% (Table 5 and Figure 4).

Data in Table 6 and Figure 5 indicated that the mortality of larvae, as reflected by percentage of larvae forming pupa was 70% (pupation 30%) when third instar larvae fed at concentration level of 12% boric acid. At the same concentration, boric acid was able to suppress emergence of adult by 95%.

Treatment of larvae medium containing third larvae with borax at the rate of 12%, only 33% of larvae able to form pupae. At 16% more effective, the mortality increases to 85% (15% pupation) and the flies emerged reduced by 90% (Table 7 and Figure 6).

Comparisons among IC50 and IC90 values showed that imidacloprid exhibited the highest effect on the inhibition of adult emergence when applied as dry formulation bait. From the probit analysis with respect of IC50 and IC90 values, imidacloprid gave (0.083-0.67%) followed by boric acid (3.7-11.6%) and borax (5.74 - 21.1%) respectively. Regarding to the relative toxicity, it’s clear that imidacloprid 68.8 times and boric acid 1.5 times as toxic as borax (Table 8 and Figure 8).

| Concentration (%) | Pupation (%) ± SD | Emergence (%) ± SD | Inhibition of Adult Emergence (%) |
|-------------------|-------------------|--------------------|----------------------------------|
| 0.0               | 100 ± 0.0         | 98 ± 0.58          | 2                                |
| 1.0               | 90 ± 0.58         | 70 ± 0.58          | 30                               |

**Figure 7:** Imidacloprid has the greatest fatal effect at both IC50 and IC90 levels followed by boric acid and then borax.

Attractive toxic sugar baits (ATSB) methods are new form of vector control. ATSB are highly effective method which targets flies based on their sugar foraging behavior by presenting baits of attractive compound. It is low cost and circumvents traditional problems related to the indiscriminate use of contact insecticides. The results of the present study indicate that both of solution or dry formulation baits could be used in the control of house fly. The lower concentration IC50 (0.083%) was observed for larvae treated rearing medium with imidacloprid in liquid and dry
formulation. For boron compounds, the inhibition of adult emergence was generally greater in those larvae treated by ATSB as liquid baits compared to dry formulation. Form probit analyses the IC50 were 0.19% and 2.6% in liquid baits and 3.7 and 5.7 for dry baits when larvae treated with boric acid and borax respectively. Also, data demonstrated that the effects of tested compound on both pupation (larval-to-pupal development) and emergence were significantly reduced at the high concentration of boron compounds. Concentrations needed were considerably greater than the effective concentration for imidacloprid. The relative efficiency revealed that, imidacloprid and boric acid 31.3 and 13.7 times more suppression of adult emergence than borax when larvae treated as liquid baits. In dry formulation baits, it is clear that imidacloprid 68.8 times and boric acid 1.5 times as to toxic as borax.

Table 8: Relative efficiency and IC values of tested compounds in solid formulation against third instar larvae of the house fly M. domestica.

In a previous studies using imidacloprid, as Larvicidal activity was observed in the direct surrounding of treated animals [67,68]. Arther et al. concluded that monthly imidacloprid application of 7.5 to 10 mg/kg will rapidly kill existing and reinvesting flea infestation in dog and break the flea life cycle by killing adult fleas before egg production begins [69-74]. Previous works mentioned that the ability of imidacloprid to suppress the yield of adult fleas on carpate (6-hours exposure) steadily declined from 82% (Day +2) to 12% (Day +43) [75-81]. Previous works mentioned that LC 50 (84 Nano-gram/L) of imidacloprid to larvae of Aedes aegypti. Uragayala et al. evaluated the Larvicidal effect of neonicotinoid insecticides against susceptible and resistant mosquito’s strains [82-96].

Boron compounds were the standard chemical use for control of larval moscoid fly population in manure [97-105], sewage ludge [106-111] and compost [112]. Recently, Hinkle et al. [113,114] mentioned borate compounds varied in efficiency against larval of cat fleas. The LC50 values of larvae exposed in treated carpet for 96 h were 23 µg/cm2 for powder boric acid, 40 µg/cm2 for granular boric acid and 47 µg/cm2 for granular polybor. Shahiduzzaman [115-119] suggested that boric acid showed highest Larvicidal effect (78.9%) followed by borax (68.9%) against larva.

Conclusion

Imidacloprid has the greatest fatal effect at both IC50 and IC90 levels followed by boric acid and then borax. In the liquid formulation, the
relative efficiency for imidacloprid and boric acid compared to borax (the least potent one), imidacloprid and boric acid achieved 31.3 and 13.7 times more suppression of adult emergence than borax. In the solid formulation, it’s clear that imidacloprid 68.8 times and boric acid 1.5 times as toxic as borax. The efficiency of tested compounds as liquid baits is higher than it as dry baits.
