We consider an extension of the Standard Model with the global symmetry-breaking pattern SO(5)/SO(4), where the Higgs boson arises as a pseudo-Nambu–Goldstone boson. The scalar content of the theory consists of a Standard-Model-like Higgs field and an extra real scalar field. The flavour sector of the model is extended by two right-handed neutrinos compatible with the observed light-neutrino phenomenology, and we find that the correct vacuum alignment determines the mass of the heavier neutrino eigenstate to be around 80 TeV. The new singlet-scalar state generates dynamically a Majorana mass term for the heavy neutrino states. We show how the model leads to the correct baryon asymmetry of the universe via leptogenesis in the case of two degenerate or hierarchical heavy neutrinos.

Preprint: CPh-Origins-2017-024 DNRF90 & HIP-2017-12/TH

I. INTRODUCTION

After the discovery of the Higgs boson and thereby the verification of the Standard-Model (SM) like electroweak symmetry-breaking (EWSB) pattern to very high accuracy, the neutrino sector provides one of the most prominent sources for beyond-SM (bSM) phenomenology. In addition to not explaining the neutrino mass and mixing patterns, the SM does not contain fields which would act as dark matter (DM), and it does not allow for dynamical explanation of baryon asymmetry of the Universe (BAU).

These issues provide motivation to explore extensions of the SM even if the present collider experiments have not revealed any direct signals of bSM physics. The absence of direct signals must be interpreted to imply that the new physics occurs either at scales beyond the current experimental reach and/or is very weakly coupled with the SM.

Here we contemplate the idea that the EWSB and neutrino mass generation be connected via a minimal extension of the SM scalar sector, and the neutrino sector, in turn, could mend the SM shortcomings in explaining the BAU and DM abundance. In this paper, we focus on the details of BAU and comment on the possible routes towards DM model building.

An attractive explanation of the Majorana nature of massive neutrinos is provided by the Seesaw mechanism [1–6], which not only gives an explanation of the smallness of neutrino masses via heavier fermionic singlets, but also gives an explanation to the observed BAU through leptogenesis [7, 8].

Connecting the neutrino mass generation to EWSB and the details of flavour physics likely require a larger scalar sector than the SM one. The compatibility with the spectrum observed at the LHC can be achieved in models predicting the Higgs as a pseudo-Nambu–Goldstone boson (pNGB); see e.g. Ref. [9] for a review of this type of models. The Higgs sector can be either elementary or composite. While the composite case is attractive as it allows to address the hierarchy problem, it lacks simple dynamics to produce the SM-fermion masses. The elementary case, on the other hand, provides a calculable framework to assess the observed symmetry-breaking pattern and low-energy spectrum [10], and facilitates an effective description of flavour physics in terms of Yukawa interactions [11] as in the SM. We will follow the latter route in this paper.

We will investigate the SO(5) → SO(4) pattern of global symmetry breaking as a renormalizable field theory simultaneously protecting the Higgs mass and reproducing a Majorana neutrino mass term. The coset of the global symmetry breaking pattern, SO(5)/SO(4), allows the presence of a SM scalar doublet using the fundamental representation for the scalar sector. Explicitly, the fundamental of SO(5) decomposes as \( 5 = 1 \oplus (2, 2) \), and therefore a scalar singlet appears in the model. The SM extension featuring a scalar singlet (also dubbed SSM) is a common renormalizable aug-
mentation of the Higgs sector and has been scrutinized in the literature; see e.g. Refs. [12–20]. Our model differs essentially from these models, since in our case the singlet exists as a part of larger multiplet due to a larger global symmetry.

We extend the SO(5)/SO(4) model by adding two right-handed (RH) neutrinos whose interaction and mixing patterns are chosen to conform with experimental results. We will find that the presence of these fields will orient the vacuum so that proper EWSB pattern ensues. This, together with properties of the vacuum, provides non-trivial constraints on the model parameters. Finally, the new matter fields will allow observed BAU to be generated via leptogenesis. The details of the mechanism are sensitive to whether the masses of the RH neutrinos are hierarchical or almost degenerate.

We find that observed BAU, together with correct pattern of EW symmetry breaking with spectrum compatible with observations, is achieved in the following scenario: the SO(5) symmetry breaks at scale of order of \( v \) in the following scenario: the SO(5) symmetry trum compatible with observations, is achieved rect pattern of EW symmetry breaking with spec-

\[ m \sim \lambda v^2 \sim O(1 \text{ TeV}^2), \]

and the trilinear Higgs coupling will be of the order of \( O(10^{-8}) \). Consequently, the heavier scalar state has mass \( m^2 \sim \lambda v^2 \sim O(1 \text{ TeV}^2) \), and the trilinear Higgs coupling will be of the order of \( O(10^{-4} \text{ TeV}) \).

The paper is organized as follows: In Sec. II we outline the details of the model. In Sec. III we analyse vacuum structure, and how this constrains the parameter space of the model. In Sec. IV we discuss how the observed BAU can be produced in this model. We analyse quantitatively the cases of degenerate or hierarchical neutrinos. In Sec. V we present our conclusions and outlook for further work.

II. THE MODEL

In this work we consider the minimal extension of the SM scalar sector incorporating an elementary pNGB Higgs. We adopt a tree-level scalar potential that features a global symmetry breaking pattern SO(5) \( \rightarrow \) SO(4). The scalar degrees of freedom are conveniently parameterized by a multiplet \( \Sigma \) describing a linear \( \sigma \)-model based on the coset SO(5)/SO(4). We adopt the following notation

\[ \Sigma = (\sigma, \Pi_1, \Pi_2, \Pi_3, \Pi_4), \]

where \( \sigma \) is a massive scalar degree of freedom and \( \Pi_i, \ i = 1, \ldots, 4 \) are the four Nambu–Goldstone (NGB) fields associated with the broken generators of SO(5). The general SO(5)-symmetric potential is given by

\[ V = \frac{1}{2} m^2 \Sigma \Sigma^c + \frac{\lambda}{4!} (\Sigma \Sigma^c)^2. \]

The electro-weak (EW) gauge group, SU(2)_L \( \times \) U(1)_Y, is embedded in SO(5) such that the three broken generators of SU(2)_L are those associated with the three NGB’s \( \Pi_i, \ i = 1, \ldots, 3 \). The field \( \Sigma \) contains an EW Higgs doublet, \( H \), and another real singlet, \( \varphi \), which are the EW interaction eigenstates. The relevant physical mass eigenstates will in general be mixtures of the neutral component of \( H \) and \( \varphi \) such that the Higgs is mostly the NGB-like state, while the heavier singlet neutral scalar is mostly the \( \sigma \)-like eigenstate.

Explicitly,

\[ H = \frac{1}{\sqrt{2}} \left( \Pi_1 + i \Pi_2 \right), \]

and in the unitary gauge we can write the potential of Eq. (2) in terms of the neutral components of the EW eigenstates, \( h = \cos \theta \Pi_1 + \sin \theta \sigma \) and \( \varphi = -\sin \theta \Pi_1 + \cos \theta \sigma \),

\[ V_0 = \frac{m_H^2}{2} h^2 + \frac{m_\varphi^2}{2} \varphi^2 + \frac{1}{4!} \lambda_H h^4 + \frac{\lambda_\varphi}{4!} \varphi^4 + \frac{\lambda_H \varphi}{12} h^2 \varphi^2, \]

with \( m_H^2(\mu_0) = m_\varphi^2(\mu_0) \equiv m^2 \), \( \lambda_\varphi(\mu_0) = \lambda_H(\mu_0) \equiv \lambda \), where the scale \( \mu_0 \) is of the order of the symmetry-breaking scale and is determined by renormalization conditions\(^1\).

The radiative symmetry-breaking dynamics implies:

\[ \langle h \rangle = v \sin \theta \equiv v_w = 246 \text{ GeV}, \]

and

\[ \langle \varphi \rangle = v \cos \theta. \]

Radiative corrections single out a value for the angle \( \theta \), and the large hierarchy \( v_w \ll v \) is reflected in \( \sin \theta \ll 1 \).

\(^1\) Note that one can relate the masses and couplings of different field components to the corresponding parameters in the SO(5)-invariant Lagrangian only at the scale where SO(5) becomes effectively restored as the couplings will run differently.
Furthermore, we introduce two RH Majorana neutrinos. We couple them via Yukawa interactions to the EW-singlet scalar state, \( \varphi \), such that the Majorana masses for the RH neutrinos are induced via the symmetry breaking. However, a generic Majorana mass term for RH neutrinos is allowed by gauge interactions, and hence the most generic Majorana mass matrix we can write is:

\[
-L^\nu = Y_{ij} N_{Ri} (L \bar{H})_j + \frac{1}{2} (N_R)^c R \alpha_{ij} N_{Rj} \\
+ \frac{1}{2} \alpha_{ij} (N_R)^c R \varphi + \text{h.c.} \tag{7}
\]

where

\[
M_D = v_\alpha Y \quad \text{and} \quad M_N = \mathcal{M} + \langle \varphi \rangle \alpha. \tag{8}
\]

We note that \( M_N \) must be symmetric due to the Majorana condition \( (N_R)^c = C N_R^T \). The Lagrangian in Eq. (7) is a realisation of the type I Seesaw. It is always possible to diagonalize \( M_N \), i.e. there exists a matrix \( V \) such that

\[
\mathcal{M} + \langle \varphi \rangle \alpha = V D_N V^T, \tag{9}
\]

with the heavy-neutrino mass matrix defined as \( (D_N)_{ij} \equiv m_{N_i} \delta_{ij} \).

**III. VACUUM ALIGNMENT ANALYSIS**

In the following, we assume a simplified structure of the bare Majorana mass matrix \( \mathcal{M} = \text{diag}(M_0, M_0) \), and consider two specific textures for \( \alpha \): diagonal and almost democratic,

\[
\alpha_0 \begin{pmatrix} 1 - \epsilon & 0 \\ 0 & 1 \end{pmatrix}, \quad \alpha_0 \begin{pmatrix} 1 & 1 - \epsilon \\ 1 & 1 \end{pmatrix}, \tag{10}
\]

where \( \epsilon \ll 1 \) is introduced to provide small splitting of masses in the diagonal case and to provide a non-zero mass contribution for the lightest eigenstate in the democratic case. In these two cases, the mass of the heavier mass eigenstate is, respectively,

\[
M_0 + |\alpha_0| v \cos \theta \quad \text{and} \quad M_0 + 2 |\alpha_0| v \cos \theta, \]

up to corrections of \( O(\epsilon) \). Next we consider the constraints arising from the vacuum alignment on the parameters \( M_0 \) and \( \alpha_0 \). We will find that vacuum alignment is mainly determined by \( \alpha_0 \), while the correct value of the Higgs boson mass imposes an upper limit for \( M_0 \).

As shown in Ref. [11], in the absence of the RH-neutrino sector, the EW gauge and top corrections prefer an unbroken EW symmetry, i.e. the value \( \theta = 0 \). Switching on the coupling \( \alpha_{ij} \) between the RH neutrinos and the singlet \( \varphi \), the picture changes, implying a non-trivial alignment angle, \( \theta \). This is due to the different dependence on the vacuum alignment angle of the RH neutrinos and the SM sector, as can be seen from Eqs. (5) and (6).

To illustrate the main features of the vacuum structure in the model under study, we first consider the simplest case setting \( M_0 = 0 \) in Eq. (8) and \( \epsilon = 0 \) in Eq. (10). For the democratic \( \alpha \)-matrix, this corresponds to one heavy neutrino since there are two eigenvalues, one of which is zero. For the diagonal \( \alpha \)-matrix, this corresponds to two degenerate heavy neutrinos.

With the choice \( M_0 = 0 \), one can obtain simple analytic expressions. Moreover, the result on the alignment angle \( \theta \) is essentially not affected by non-zero values of \( M_0 \). This is due to the fact that allowing non-zero \( M_0 \) does not alter the \( \theta \)-dependence of the neutrino contribution to the one-loop effective potential.

To arrive at a simple analytic expression for the non-trivial solution for the vacuum alignment angle, we also ignore the one-loop corrections from the scalar sector. In the numerical analysis, we include all these corrections and show that the results for the alignment do not essentially change from the simplified results. In this simplified limit, the effective potential up to the one-loop level can be written as

\[
V_{\text{eff}} = V_0 + V_1^{\text{SM}} + V_1^\nu, \tag{11}
\]

where following the notations of Ref. [11], the one-loop contributions in the \( \sigma \)-background and in the \( \overline{\text{MS}} \) scheme can be written as

\[
V_1^{\text{SM}} = \frac{3 g^4 \sigma^4 \sin^4 \theta}{64 \pi^2} \cdot \left( A_{\text{SM}} \log \frac{g^2 \sigma^2 \sin^2 \theta}{\mu_0^2} + B_{\text{SM}} \right),
\]

\[
V_1^\nu = \frac{|\alpha_0|^4}{32 \pi^2} \sigma^4 \cos^4 \theta \cdot \left( A_{\nu} \log \frac{|\alpha_0|^2 \sigma^2 \cos^2 \theta}{\mu_0^2} + B_{\nu} \right), \tag{12}
\]

With these expressions, we numerically analyse all the possible scenarios for the one-loop contributions in the neutrino sector.
where we define
\[ A_{\text{SM}} = \frac{1}{16} \left[ \left( \frac{g^2 + g'^2}{g^2} \right)^2 + 2 \right] - \frac{y_t^4}{g^4}, \]
\[ B_{\text{SM}} = \frac{1}{16} \left[ 8 y_t^4 \left( 3 - \log \frac{y_t^4}{4 g^4} \right) - 5 - \log 16 + \left( \frac{g^2 + g'^2}{g^2} \right)^2 \left( \log \frac{g^2 + g'^2}{4 g^2} - \frac{5}{6} \right) \right], \]
\[ A_{\nu}^{\text{diag}} = -2, \quad A_{\nu}^{\text{democ}} = -16, \tag{13} \]
\[ B_{\nu}^{\text{diag}} = 3, \quad B_{\nu}^{\text{democ}} = -16 \left( 2 \log 2 - \frac{3}{2} \right). \]

We choose the renormalization scale, \( \mu_0 \), such that the tree-level vacuum expectation value, \( \langle \sigma \rangle = v \), is not changed by the one-loop corrections and determine the preferred value of the vacuum alignment by minimizing the effective potential with respect to \( \theta \). This yields the following non-trivial solution for \( \theta \):
\[ \tan^2 \theta = \frac{-2 A_{\nu} |\alpha_0|^4}{3 A_{\text{SM}} g^4} \]
\[ = \frac{512 |\alpha_0|^4}{3 \left( 16 y_t^4 - 3g^4 - 2g^2 g'^2 - g'^4 \right)}. \tag{14} \]

We assume the SM-like RG running of the gauge and top-Yukawa couplings up to the renormalisation scale, \( \mu_0 \).

In this simplified limit, the \( \overline{\text{MS}} \) mass of the Higgs can be written as
\[ (m_h)_{\overline{\text{MS}}}^2 = \frac{3 g^4 v^2}{16 \pi^2 A_{\nu} (2 A_{\nu} |\alpha_0|^4 - 3 A_{\text{SM}} g^4)} \left[ -3 A_{\text{SM}} g^4 (2 A_{\nu} A_{\nu} - 3 A_{\text{SM}} B_{\nu} + 3 A_{\nu} B_{\text{SM}}) + 2 A_{\nu} |\alpha_0|^4 (2 A_{\text{SM}} A_{\nu} + 3 A_{\text{SM}} B_{\nu} - 3 A_{\nu} B_{\text{SM}}) + 3 A_{\text{SM}} A_{\nu} (3 A_{\text{SM}} g^4 + 2 A_{\nu} |\alpha_0|^4) \log \left( -\frac{3 A_{\text{SM}} g^2}{2 A_{\nu} |\alpha_0|^2} \right) \right]. \tag{15} \]

Once we have the expression for the \( \overline{\text{MS}} \) mass, we calculate the physical mass following Refs.\ [21, 22]\.

Next, we turn to the full numerical analysis including the one-loop corrections from the scalar sector and adding a non-zero Majorana mass parameter, \( M_0 \). The values for the symmetry-breaking scale and the absolute value of the Majorana-neutrino Yukawa coupling, \( |\alpha_0| \), for a stable minimum solution producing the correct Higgs mass are given in Fig. 1. We find that increasing the hard Majorana mass parameter \( M_0 \), while requiring a stable minimum with respect to the angle \( \theta \), constrains the minimum allowed physical mass of the Higgs. We show this dependence in Fig. 2.

The democratic or diagonal \( \alpha \)-matrix implies two hierarchically separated or two degenerate mass eigenvalues and, therefore, corresponds respectively to one or two heavy RH flavours. In Fig. 3 we show how the value of the symmetry-breaking scale and the value of the Majorana Yukawa coupling depend on these two possibilities for the RH-neutrino mass textures. We have fixed \( m_h^{\text{SM}} = 128 \text{ GeV} \) to account for the correct physical Higgs mass. We note that in both cases the value of the heaviest neutrino turns out to be around 80 TeV.

\[ 10^{-4} \nu \text{ [TeV]} \]
\[ 10^{-3} |\alpha_0| \]
\[ M_0 \text{ [TeV]} \]

\[ 10 \]
\[ 5 \]
\[ 0.5 \]
\[ 1 \]
\[ 0.0 0.5 1.0 1.5 2.0 2.5 3.0 \]

**FIG. 1.** The values of the vacuum expectation value and the (absolute value of the) Majorana Yukawa coupling, \( |\alpha_0| \), as a function of \( M_0 \), when the correct Higgs mass and the vacuum solution are imposed. Solid (dashed) lines correspond to democratic (diagonal) \( \alpha \)-matrices in Eq.\( (10) \).

**IV. SEE-SAW MECHANISM AND LEPTOGENESIS**

Baryogenesis via leptogenesis [8] is a simple mechanism to explain the baryon number asymmetry of the Universe (BAU). The asymmetry is
In this Section, we study the different possibilities to produce the observed amount of the BAU within the model presented in the previous section. We restrict ourselves to the minimal RH-neutrino sector with two heavy flavours to illustrate the main features of generating BAU. We note, however, that extending the neutrino sector with a third RH neutrino would allow for a DM candidate alike the one considered e.g. in Refs. [25–27]. Furthermore, the addition of a third, lighter RH neutrino would not affect the vacuum structure, since this is predominantly determined by the heaviest state. We leave, however, the study of DM phenomenology to future work, and concentrate here on details of how to generate the BAU.

Interestingly the two simple forms of \( \alpha \) given in Eq. (10) imply different possibilities for the production of the baryon asymmetry in this model: the diagonal form will allow for resonant leptogenesis, while the democratic one will allow for non-resonant standard scenario.

We express the neutrino Dirac-Yukawa couplings through the Casas-Ibarra parameterization [28]. We notice that this parameterization is valid also in presence of additional contributions to the bare Majorana-neutrino mass term. Indeed, in a generic basis for the heavy Majorana-neutrino mass matrix, \( M_N \), we write:

\[
M_D = iU_{PMNS}' D_\nu \sqrt{D_N} V^\dagger,
\]

with the diagonal heavy and light neutrino mass matrices defined respectively as \( (D_N)_{ij} = m_N \delta_{ij} \) and \( (D_\nu)_{ij} = m_i \delta_{ij} \), with \( m_i \) < 1 eV and \( i = 1, 2, 3 \).

The matrix \( U_{PMNS} \) is the Pontecorvo–Maki–Nakagawa–Sakata matrix describing leptonic interactions, \( \Omega \) is a general \( 3 \times 3 \) complex matrix that can be parameterized as \( \Omega = R(\theta_{23})R(\theta_{13})R(\theta_{12}) \) with \( \theta_{ij} \) complex, and \( V \) is the matrix diagonalizing the RH Majorana mass matrix. Similarly to the standard type I See-Saw scenario, one can go to the basis where the the RH Majorana mass matrix is diagonal, i.e. \( V \) is set to unity.

In the analysis that follows, we will restrict ourselves to the minimal case of two heavy RH neutrinos,

\[
M_N = \text{diag}(M_1, M_2),
\]

and parameterize two different regimes in terms of \( \delta \equiv (M_2 - M_1)/M_1 \):

- degenerate masses for \( \delta \ll 1 \)
- hierarchical spectrum for \( \delta \gg 1 \),

In the analysis that follows, we will restrict ourselves to the minimal case of two heavy RH neutrinos,

\[
\eta_B = \frac{n_B - n_B^\circ}{n_\gamma} \simeq (6.08 \pm 0.04) \times 10^{-10}.
\]

The effect of non-perturbative \((B + L)\)-violating sphaleron processes can convert a lepton asymmetry into a baryon asymmetry [7, 8]. This scenario can well be implemented within the See-Saw (type I) mechanism [1–4]: in the thermal leptogenesis scenario, after the inflation period, the heavy RH neutrinos are produced by thermal scatterings, and subsequently they can decay out-of-equilibrium producing both lepton and CP number violation, therefore satisfying all of the Sakharov’s conditions (see Ref. [24] for a review).
corresponding to our choice of a diagonal or a democratic $\alpha$-matrix, respectively. Producing the correct EW spectrum and the Higgs mass fixes the mass of the heaviest RH neutrino to be not heavier than about 80 TeV. Therefore, the simplest hierarchical leptogenesis scenario is not possible due to the Davidson–Ibarra bound [29] on the lightest RH neutrino mass. A possible solution to circumvent this bound, and achieve a viable low-energy leptogenesis scenario is to consider nearly degenerate RH-neutrino masses, the so-called resonant leptogenesis [30, 31]. We will consider this scenario in Sec. IV A.

An alternative low-energy scenario considered in Ref. [32] is the case where the couplings between the RH neutrinos and the singlet scalar provide an additional source of CP violation, and allow to avoid the Davidson–Ibarra bound. In this case both the bare Majorana mass and the off-diagonal mass term, $\alpha_{ij}$, $i \neq j$, are needed to produce a successful baryogenesis scenario. We consider a minimal extension of the model to allow for this leptogenesis scenario in Sec. IV B.

## A. Scenario I: Resonant leptogenesis

Here we consider the case where the two RH neutrinos are quasi-degenerate, and the oscillations between different neutrino flavours provide a sufficient enhancement of CP violation. This scenario is dubbed resonant leptogenesis [30, 31], and it has been extensively studied in connection to the Dirac and/or Majorana CP-violating phases in the PMNS neutrino mixing matrix [33]. For recent developments, see e.g. Refs. [34–36]. This scenario is particularly interesting since it can directly relate the low-energy CP violation in the lepton sector to the BAU.

To estimate the asymmetry, we follow Refs. [27, 33, 37], and the corresponding details about the resonant leptogenesis scenario can be found in Appendix A 1. We consider two heavy RH neutrinos with masses $M_1$ and $M_2$ which, in the notation of Eq. (7), satisfy

$$\delta \equiv (M_2 - M_1)/M_1 \gg \frac{(Y^\dagger Y)_{12}}{16\pi^2}. \quad (19)$$

We assume that the baryon-to-photon ratio at recombination satisfies $\eta_B \simeq 0.01 N_{B-L}^f$, where $N_{B-L}^f$ is explicitly given in Eq. (A1). The proportionality constant contains the sphaleron conversion factor, $a_{\text{ sph}}$, which for SM particle content is $28/79 \approx 1/3$, and the dilution due to the photon production between the leptogenesis scale and the scale of recombination, $1/f = 86/2387 \approx 1/30$ assuming the standard isentropic expansion [38].

The end result of the analysis for the normal hierarchy of the active neutrinos is

$$\delta \simeq 0.8 \times 10^{-7} \left(\frac{f(m_\nu, \Omega)}{f_{\text{max}}} \right) \left(\frac{M_1}{10^4 \text{GeV}}\right), \quad (20)$$

where $f_{\text{max}} \simeq 0.005$, and the function $f$, defined explicitly in Appendix A 1, incorporates the dependence on the light-neutrino masses, $m_\nu$, and mixings via $\Omega$. With RH neutrinos at scale $M_1 \sim 80$ TeV, the degeneracy of the order of $\delta \lesssim 10^{-7}$ is expected for a viable leptogenesis scenario.

Hence, this scenario requires considerable fine tuning in the mass spectrum, but nevertheless provides a viable scenario to produce the observed BAU.

## B. Scenario II: Hierarchical masses

Let us now consider leptogenesis in the case where the RH neutrinos of the model have hierarchical masses, i.e. $\delta = (M_2 - M_1)/M_1 \gg 1$. Our model contains the same degrees of freedom as the one considered in detail in Ref. [32]. We therefore follow their prescription to implement the two-stage Boltzmann equations taking the interactions of the singlet scalar into account. The relevant processes for the Boltzmann equations are $O(Y^2)$, $O(Y^4)$, and $O(Y^2 \alpha^2)$ corresponding to $\Delta L = 1$ decays, $\Delta L = 2$ scatterings, and $\Delta L = 1$ scatterings, respectively.

The additional CP violation due to the extra scalar is generated by $N_2 \to LH$ decays via $N_1 N_2 \varphi$ interactions. The lighter neutrino, $N_1$, remains in equilibrium and can mediate potentially dangerous washout processes. However, if $N_1$ is weakly-enough coupled, then this washout effect is suppressed, and does not disturb the enhancement of the CP violation [32].

The coupled equations for the abundances of the two neutrino flavours, $Y_1$ and $Y_2$, and the lepton asymmetry $Y_{L-L}$ are
\[ z_1 \frac{\partial Y_{L-L}}{\partial z_1} = \epsilon_1 D_1 \left( \frac{Y_1}{\sqrt{v_1^2}} - 1 \right) + \epsilon_2 D_2 \left( \frac{Y_2}{\sqrt{v_2^2}} - 1 \right) - Y_{L-L} (W_{1D_1} + W_{S_1} + W_{1D_2} + W_{S_2}), \quad (21) \]

\[ z_1 \frac{\partial Y_1}{\partial z_1} = -\left( \frac{Y_1}{\sqrt{v_1^2}} - 1 \right) (D_1 + D_{21} + S_1) + \left( \frac{Y_2}{\sqrt{v_2^2}} - 1 \right) D_{21} - \left( \frac{Y_1 Y_2}{v_1^2 v_2^2} - 1 \right) S_{N_1 N_2 \to HH} \left( 2 \frac{Y_2}{v_2^2} - 1 \right) S_{N_1 N_2 \to HH}, \quad (23) \]

\[ z_1 \frac{\partial Y_2}{\partial z_1} = -\left( \frac{Y_2}{\sqrt{v_2^2}} - 1 \right) (D_2 + D_{21} + S_2) + \left( \frac{Y_1}{\sqrt{v_1^2}} - 1 \right) D_{21} - \left( \frac{Y_1 Y_2}{v_1^2 v_2^2} - 1 \right) S_{N_1 N_2 \to HH} - \left( \frac{Y_2}{v_2^2} - 1 \right) S_{N_2 N_2 \to HH}, \quad (25) \]

where \( Y_i = n_i/n_i^{eq} \), \( z_i = M_i/T \), \( z_2 = z_1 M_2/M_1 \), and

\[ Y_i^{eq} = 3 \sqrt{2} K_2(z_i). \quad (26) \]

Here \( K_2(z) \) is the modified Bessel function of the second kind. The CP violation is parameterized by

\[ \epsilon_i \equiv \frac{\Gamma(N_i \to LH) - \Gamma(N_i \to LH^\dagger)}{\Gamma(N_i \to LH) + \Gamma(N_i \to LH^\dagger)}, \quad (27) \]

and the functions denoted by \( \Gamma \), \( D \), \( S \), and \( W \) correspond to different decay, scattering and washout processes. The functions \( D \), \( S \), and \( W \) are defined in Appendix A 2, while the decay rates, \( \Gamma \), are defined in Appendix B 1.

We can now directly proceed to present the numerical results we obtain for our model. The scalar sector has three parameters, \( m_{\Sigma}, \lambda \) and the angle, \( \theta \), while the leptonic sector depends on \( \alpha_0 \), \( \epsilon \), \( M_0 \) and the Yukawa matrix, \( Y \). The constraints on vacuum alignment and correct mass for the Higgs boson leave \( M_0, \epsilon, Y, \) and \( \lambda \) as free parameters. The Yukawa matrix, \( Y \), enters through the decay rates \( \Gamma_i = \Gamma(N_i \to LH) + \Gamma(N_i \to LH^\dagger) \) and \( \epsilon \) through \( \Gamma_{21} = \Gamma(N_2 \to N_1 \varphi) \) given explicitly in Eq. (B2). A convenient parametrization is given by considering the equilibrium parameters \( K_i, i = 1, 2, \) and 12,

\[ K_i \equiv \frac{\Gamma_i}{H_i} = \frac{\bar{m}_i}{m_*}, \quad K_{21} \equiv \frac{\Gamma_{21}}{H_2}, \quad (28) \]

and we define

\[ \bar{m}_i = \frac{(YY^\dagger)_{ii}v_W^2}{2M_i}, \quad m_* \equiv 4\pi v_W^2 \sqrt{\frac{8\pi^3 g_*}{90 M_P^2}} \quad (29) \]

and the Hubble rate is given by:

\[ H(T) = T^2 \sqrt{\frac{8\pi^3 g_*}{90 M_P^2}}, \quad H_i \equiv H(T = M_i). \quad (30) \]

The value of the lepton asymmetry is rather sensitive to the value of \( \epsilon \), and the parameter \( M_0 \) is constrained to be relatively small, \( M_0 \lesssim 3 \) TeV (see Fig. 2), from the Higgs mass requirement. In Fig. 4 we show the resulting abundances of the two neutrino species obtained from the Boltzmann equations together with the corresponding equilibrium densities, and the net lepton abundance. To obtain the observed BAU, the net lepton abundance must be \( \eta_L \equiv Y_{L-L} = 1.1 \cdot 10^{-9} \). The cross sections of the relevant processes are given in Appendix B. A benchmark set of parameters (case 1) leading to the desired value is given by \( \epsilon = 2.3 \cdot 10^{-4} \), \( |\alpha_0| = 1.23 \cdot 10^{-3} \) and \( M_0 = 0.4 \) TeV. The mass of the heavier neutrino is fixed by the vacuum alignment to 79.5 TeV, while with the above parameters the mass of the lighter one becomes 8.6 TeV. The values of the light-neutrino Yukawa couplings, \( Y \), enter the analysis via factors \( K_1 = 0.01, K_2 = 4.0 \). The scalar self-coupling enters through the trilinear coupling \( \beta \varphi (H^\dagger H) \), \( \beta = 2.5 \cdot 10^{-4} \) TeV. Finally, with these parameters the mass of the singlet scalar is \( M_\varphi = 3.0 \) TeV.

This result is clearly sensitive to the values of the parameters involved in the analysis. We have checked that changing the parameter \( M_0 \) by a factor of two has hardly an effect for the asymmetry. This is expected, as \( M_0 \) does not affect the amount of CP violation. On the other hand, the effects of varying \( \epsilon \) in Eq. (10) and the light neutrino mass parameters entering via \( K_2 \) have big effects on the resulting lepton asymmetry. For concreteness, we show in Fig. 5 the results considering \( \epsilon \to 2\epsilon \) (case 2), and \( K_2 \to 10K_2 \) (case 3). In Table I we list
TABLE I. We show the values of the model parameters, 
$K_2$, $\alpha_0$, $\epsilon$, $\beta$, and the values of $v$ and $M_1$ for the cases 1–3 (see the text for details). All masses and $v$ are in TeV. The heavy neutrino masses, $M_1$ and $M_2$, are determined by the vacuum and the matrix $\alpha$. For all the cases we use the same following benchmark values of the remaining parameters: $K_1 = 0.01$, $M_0 = 0.4$ TeV, and $M_2 = 3.0$ TeV. The mass of heavier neutrino is the same, $M_2 = 79.5$ TeV, for all the cases.

| # | $K_2$ | $10^4|\alpha_0|$ | $10^4\epsilon$ | $10^4\beta$ | $10^{-4}v$ | $M_1$ |
|---|---|---|---|---|---|---|
| 1 | 4.0 | 12.3 | 2.3 | 2.5 | 3.5 | 8.6 |
| 2 | 4.0 | 13.5 | 4.6 | 2.5 | 3.5 | 16.7 |
| 3 | 40 | 12.3 | 2.3 | 2.5 | 3.5 | 8.6 |

For comparison, the dashed purple line shows our enhanced, while in the third case is suppressed. In the second case the final lepton asymmetry is the values of the benchmark point (case 1) and $K_1$ with mass hierarchy $M_2 = 79.5$ TeV and $M_1 = 8.6$ TeV. Shown in the figure are the abundances of the two neutrinos with solid blue and red lines. The dashed lines show the corresponding equilibrium densities. The purple curve shows the resulting net lepton abundance normalized by a factor $10^{-8}$ so that the value corresponding to observed BAU is $Y_{\ell} - \epsilon = 0.11 \cdot 10^{-8}$ shown by the horizontal dot-dashed line.

From the numerical results we see that the effect due to changing $\epsilon$ can be compensated for by changing $K_2$ accordingly. As a consequence, one may expect that a sizeable portion of parameter space exists, within which the observed BAU can be produced by this model.

V. CONCLUSIONS

In this paper we have considered an extension of the SM where the Higgs boson arises as a pseudo-Nambu–Goldstone boson. As a concrete framework, we have considered the SO(5)/SO(4) coset in terms of elementary scalar fields. The scalar content of the theory is accommodated in the fundamental of SO(5), and in addition to SM Higgs sector it contains a real singlet scalar field. Furthermore, we added two heavy RH neutrinos to explain the masses and mixings of the light neutrinos and also to generate BAU via leptogenesis. The neutrino Majorana masses are generated through the interplay between a bare mass term and a mass term arising dynamically from the vacuum expectation value of the scalar singlet.

We found that the vacuum structure and the mass of the Higgs boson imply stringent bounds on the model parameters. In particular, we demonstrated that these lead to the requirement that the heavier of the two RH neutrino mass eigenvalues is $\sim 80$ TeV.

This in turn has consequences for the generation of the BAU via leptogenesis. As we have discussed, this depends sensitively on the assumed mass patterns of the RH neutrinos. We analysed in detail the cases of degenerate and hierarchical RH neutrinos, and identified examples of viable values of the parameters.

One could extend the model by adding a third RH neutrino as well. This would be a suitable can-
didate for dark matter given a vanishing mixing of this state with the two other RH neutrinos. The vacuum analysis would not be affected by its presence as we have shown that the vacuum alignment is determined only by the heaviest RH neutrino states. Furthermore, our analysis of BAU would also remain unaffected.

Appendix A: Definitions

1. Definitions for resonant leptogenesis

To estimate the $B - L$ asymmetry, we follow Refs. [27, 33, 37]. The final asymmetry is given as a sum of the contributions from the two lightest RH neutrinos, and three lepton flavours

$$N_{B-L}^f = \sum_{i,\alpha} N_{\Delta_{i\alpha}} = \sum_{i,\alpha} \epsilon_{i\alpha} \kappa(K_{1\alpha} + K_{2\alpha}),$$  \hspace{1cm} (A1)

where $i = 1, 2$, $\alpha = e, \mu, \tau$, and we define:

$$\epsilon_{i\alpha} \equiv -\frac{\Gamma_{i\alpha} - \bar{\Gamma}_{i\alpha}}{\sum_\alpha (\Gamma_{i\alpha} + \bar{\Gamma}_{i\alpha})}, \quad K_{i\alpha} \equiv \frac{\Gamma_{i\alpha} + \bar{\Gamma}_{i\alpha}}{H(T = M_i)} = \frac{|m_{D\alpha i}|^2}{M_i m_*}. \hspace{1cm} (A2)$$

and

$$\kappa(x) \equiv 2 x z_B(x) \left[ 1 - \exp \left( -\frac{x z_B(x)}{2} \right) \right], \text{ where } z_B(x) \simeq 2 + 4 x^{0.13} e^{-2x}. \hspace{1cm} (A3)$$

In the degenerate limit, the final asymmetry can be written as

$$N_{B-L}^f \simeq \bar{\epsilon}(M_1) \left( \frac{1}{K_1} + \frac{1}{K_2} \right) \sum_\alpha \kappa(K_{1\alpha} + K_{2\alpha}) \left( T_{12}^\alpha + J_{12}^\alpha \right), \hspace{1cm} (A4)$$

where

$$T_{ij}^\alpha \equiv \frac{\text{Im} \left[ m_{D\alpha i} m_{D\alpha j} (m_{D}^\dagger m_D)_{ij} \right]}{M_i M_j m_{\text{atm}} m_*},$$
$$J_{ij}^\alpha \equiv \frac{\text{Im} \left[ m_{D\alpha i} m_{D\alpha j} (m_{D}^\dagger m_D)_{ji} \right]}{M_i M_j m_{\text{atm}} m_*} \frac{M_i}{M_j}; \hspace{1cm} (A5)$$

and

$$\bar{K}_i \equiv \sum_\alpha K_{i\alpha}, \quad i = 1, 2. \hspace{1cm} (A6)$$

Assuming that the baryon-to-photon ratio at recombination satisfies $\eta_B \simeq 0.01 N_{B_L}^f$, for normal hierarchy it is found

$$\delta_2 \simeq 0.01 \frac{\bar{\epsilon}(M_1)}{\eta_B} f(m_\nu, \Omega) \hspace{1cm} (A7)$$
$$\simeq 0.8 \times 10^{-5} \left( \frac{f(m_\nu, \Omega)}{f_{\text{max}}} \right) \left( \frac{M_1}{10^6 \text{ GeV}} \right),$$

where $f_{\text{max}} \simeq 0.005$, and the function $f$ incorporates the dependence on the light-neutrino masses and mixings:

$$f(m_\nu, \Omega) \equiv \frac{1}{3} \left( \frac{1}{K_1} + \frac{1}{K_2} \right) \sum_\alpha \kappa(K_{1\alpha} + K_{2\alpha}) \left( T_{12}^\alpha + J_{12}^\alpha \right). \hspace{1cm} (A8)$$
2. Definitions for the hierarchical case

In this Appendix we give the decay, scattering and washout functions that appear in the Boltzmann equations, Eq. (21). We follow the notations of Ref. [32]. We define

\[ W_1 \equiv \frac{1}{2Y_L^2} D_1 \quad \text{where} \quad D_1 \equiv \frac{\gamma_{eq}}{n_\gamma H} K_1(z_i) \frac{Y_i}{K_2(z_i)}, \]  

(A9)

\[ D_{21} \equiv K_{21} \frac{z_2}{2} Y_{eq} K_1(z_2) \frac{Y_i}{K_2(z_2)}. \]  

(A10)

The scattering function for the process \( ij \to mn \) reads:

\[ S_{ij \to mn} \equiv \frac{\gamma_{eq}}{n_\gamma H} \frac{m_i}{g_{ij}} \int_{w_{\text{min}}}^{\infty} dw \sqrt{w} K_1(\sqrt{w}) \tilde{\sigma}_{ij \to mn}(w \frac{m_2^2}{z_i}), \]  

(A11)

\[ w_{\text{min}} = \max\{(m_i + m_j)^2, (m_m + m_n)^2\}. \]  

(A12)

We define

\[ W_{S1} = \frac{1}{Y_L^2} \left( 2 S_{N1t \to LQ} + S_{N1H \to L\phi} + S_{N1\varphi \to LH} \right) + \frac{Y_1}{Y_L Y_{eq}} (S_{N1L \to Qt} + S_{N1L \to H\phi}), \]

\[ W_{S2} = \frac{1}{Y_L^2} \left( 2 S_{N2t \to LQ} + S_{N2H \to L\phi} + S_{N2S \to LH} + S_{N2S \to LH} \right) + \frac{Y_2}{Y_L Y_{eq}} (S_{N2L \to Qt} + S_{N2L \to H\phi}), \]  

(A13)

and

\[ S_1 = 2S_{N1L \to Qt} + 4S_{N1Q \to Lt} + 2S_{N1L \to H\phi} + 4S_{N1H \to L\phi} + 2S_{N1\varphi \to LH}, \]

\[ S_2 = 2S_{N2L \to Qt} + 4S_{N2Q \to Lt} + 2S_{N2L \to H\phi} + 4S_{N2H \to L\phi} + 2S_{N2\varphi \to LH} + 2S_{N2\varphi \to LH}. \]  

(A14)

Appendix B: Cross sections

All the cross sections are summed over both the initial and final state degrees of freedoms (gauge, spins, lepton flavour). In some of the formulas we have found slightly different coefficients compared to [32].

1. Decay widths

\[ \Gamma_i \equiv \Gamma(N_i \to LH) + \Gamma(N_i \to LH) = \frac{\langle YY^\dagger \rangle_{ii} M_i}{8\pi}. \]  

(B1)

\[ \Gamma_{ji} \equiv \Gamma(N_j \to Ni\varphi) = \frac{(\alpha^2 \alpha_{ji})^2 M_j}{16\pi} \left[ (1 + \frac{M_i}{M_j})^2 \frac{M_i^2}{M_j^2} \right] \sqrt{\left( 1 - \frac{M_i^2}{M_j^2} \right)^2 - 4\frac{M_i^2 M_j^2}{M_i^2}}. \]  

(B2)
2. Scattering cross sections

Below we tabulate the relevant cross sections $\sigma(ij \rightarrow mn)$. The reduced cross sections are obtained from these as

$$\hat{\sigma}(ij \rightarrow mn) = \frac{1}{s} \delta(s, m_i^2, m_j^2) \sigma(ij \rightarrow mn), \quad (B3)$$

where

$$\delta(a, b, c) = a^2 + b^2 + c^2 - 2ab - 2ac - 2bc. \quad (B4)$$

a. $N_i L \rightarrow Q\bar{t}$

$$\sigma(N_i L \rightarrow Q\bar{t}) = \frac{N_c (YY^\dagger)_{ii} y_t^2}{8\pi} \frac{s}{(s - m_h^2)^2}. \quad (B5)$$

b. $N_i Q \rightarrow Lt$

$$\sigma(N_i Q \rightarrow Lt) = \frac{N_c (YY^\dagger)_{ii} y_t^2}{8\pi(s - M_i^2)^2} \left[ s - 2M_i^2 + 2m_h^2 \frac{M_i^2 - 2m_h^2}{s - M_i^2} \log \frac{s - M_i^2 + m_h^2}{m_h^2} \right]. \quad (B6)$$

c. $N_i L \rightarrow H\varphi$

$$\sigma(N_i L \rightarrow H\varphi) = \frac{(YY^\dagger)_{ii} \beta^2}{8\pi} \frac{s - M_\varphi^2}{s^3}. \quad (B7)$$

d. $N_i \varphi \rightarrow LH$ via $N_j$

$$\sigma(N_i \varphi \rightarrow LH) = \frac{N_c (YY^\dagger)_{ij} |(\alpha\alpha^\dagger)_{ji}|^2}{16\pi(s - M_j^2)^2 \sqrt{\delta(s, M_i^2, M_\varphi^2)}} \left[ (s + M_i^2 - M_\varphi^2)(s + M_j^2) - 4M_i M_j s \right]. \quad (B8)$$

e. $N_i N_j \rightarrow HH$

$$\sigma(N_i N_j \rightarrow HH) = \frac{|(\alpha\alpha^\dagger)_{ji}|^2 \beta^2}{8\pi} \frac{s - (M_i + M_j)^2}{(s - M_\varphi^2)^2 \sqrt{\delta(s, M_i^2, M_j^2)}}. \quad (B9)$$

f. $N_i H \rightarrow L\varphi$

$$\sigma(N_i H \rightarrow L\varphi) = \frac{(YY^\dagger)_{ii} \beta^2}{16\pi(s - M_i^2)^2} \log \frac{s^2(s - M_i^2 - M_\varphi^2)^2 + s^2\xi_i^2}{M_i^4 M_\varphi^2 + s^2\xi_i^2}. \quad (B10)$$
