Abstract

In this paper we present the results of comparing a statistical tagger for German based on decision trees and a rule-based Brill-Tagger for German. We used the same training corpus (and therefore the same tag-set) to train both taggers. We then applied the taggers to the same test corpus and compared their respective behavior and in particular their error rates. Both taggers perform similarly with an error rate of around 5%. From the detailed error analysis it can be seen that the rule-based tagger has more problems with unknown words than the statistical tagger. But the results are opposite for tokens that are many-ways ambiguous. If the unknown words are fed into the taggers with the help of an external lexicon (such as the Gertwol system) the error rate of the rule-based tagger drops to 4.7%, and the respective rate of the statistical taggers drops to around 3.7%. Combining the taggers by using the output of one tagger to help the other did not lead to any further improvement.

1 Introduction

In recent years a number of part-of-speech taggers have been developed for German. (Lezius et al., 1996) list 6 taggers (all of which work with statistical methods) and provide comparison figures. They report that for a “small” tagset the accuracy of these 6 taggers varies from 92.8% to 97%. But these figures do not tell us much about the comparative behavior of the taggers since the figures are based on different tagsets, different training corpora, and different test corpora. A more rigorous approach to comparison is necessary to obtain valid results. Such an approach has been presented by (Teufel et al., 1996). They have developed an elaborate methodology for comparing taggers including tagger evaluation, tagset evaluation and text type evaluation.

Tagger evaluation Tests allowing to assess the impact of different tagging methods, by comparing the performance of different taggers on the same training and test data, using the same tagset.

Tagset evaluation Tests allowing to assess the impact of tagset modifications on the results, by using different versions of a given tagset on the same texts.

Text type evaluation Tests allowing to assess the impact of linguistic differences be-
between training texts and application texts, by using texts from different text types in training and testing, tagsets and taggers being unchanged otherwise.

In this paper we will focus on “Tagger evaluation” for the most part, and only in section 5 will we briefly sidestep to “Text type evaluation”.

(Teufel et al., 1996) used their methodology only on two statistical taggers for German, the Xerox HMM tagger (Cutting et al., 1992) and the TreeTagger (Schmid, 1995; Schmid and Kempe, 1996). On contrast, we will compare one of these statistical taggers, the TreeTagger, to a rule-based tagger for German, the Brill-Tagger (Brill, 1992; Brill, 1994). Such a comparison is worthwhile since (Samuelsson and Voutilainen, 1997) have shown for English that their rule-based tagger, a constraint grammar tagger, outperforms any known statistical tagger.

2 Our Tagger Evaluation

For our evaluation we used a manually tagged corpus of around 70'000 tokens which we obtained from the University of Stuttgart. The texts in that corpus are taken from the Frankfurter Rundschau, a daily newspaper. We split the corpus into a 7/16 training corpus (60'710 tokens) and a 1/18 test corpus (8'887 tokens) using a tool supplied by Eric Brill that divides a corpus sentence by sentence. The test corpus then contains sentences from many different sections of the corpus. The average rate of ambiguity in the test corpus is 1.50. That means that on average for any token in the test corpus there is a choice of 1.5 tags in the lexicon, if the token is in the lexicon. 1342 tokens from the test corpus were not in lexicon, 5401 tokens in the test corpus have exactly one tag in the lexicon, 993 tokens have two tags in the lexicon and so on. Column 3, labelled ‘correct’, displays the number of tokens correctly tagged by the TreeTagger.

2.1 Training the TreeTagger

In a first phase we trained the TreeTagger with its standard parameter settings as given by the author of the tagger. That is, it was trained with

1. Context length set to 2 (number of preceding words forming the tagging context). Context length 2 corresponds to a trigram context.
2. Minimal decision tree gain set to 0.7. If the information gain at a leaf node of the decision tree is below this threshold, the node is deleted.
3. Equivalence class weight set to 0.15. This weight of the equivalence class is based on probability estimates.
4. Affix tree gain set to 1.2. If the information gain at a leaf of an affix tree is below this threshold, it is deleted.

The training took less than 2 minutes and created an output file of 630 kByte. Using the tagger with this output file to tag the test corpus resulted in an error rate of 4.73%. Table 1 gives an overview of the errors.

---

---
| ambiguity | tokens | correct | LE | DE |
|-----------|--------|---------|----|----|
| 0         | 1342   | 1128    | 214| 0  |
| 1         | 5401   | 5330    | 71 | 0  |
| 2         | 993    | 929     | 3  | 61 |
| 3         | 795    | 757     | 0  | 38 |
| 4         | 260    | 240     | 0  | 20 |
| 5         | 96     | 83      | 0  | 13 |
| total     | 8887   | 8467    | 288| 132|

Table 1: Error statistics of the TreeTagger

That are not in the lexicon (84.05%) and for tokens that are many ways ambiguous (86.46% for tokens that are 5-ways ambiguous).

The errors made by the tagger can be split into lexical errors (LE; column 4) and disambiguation errors (DE; column 5). Lexical errors occur when the correct tag is not available in the lexicon. All errors for tokens not in the lexicon are lexical errors (214). In addition there are a total of 74 lexical errors in the ambiguity rates 1 and 2 where the correct tag is not in the lexicon. On the contrary, disambiguation errors occur when the correct tag is available but the tagger picks the wrong one. Such errors can only occur if the tagger has a choice among at least two tags. Thus we get a rate of 3.24% lexical errors and 1.49% disambiguation errors adding up to the total error rate of 4.73%.

It should be noted that this error rate is higher than the error rate given for the TreeTagger in (Teufel et al., 1996). There, the TreeTagger had been trained over 62'860 tokens and tested over 13'416 tokens of a corpus very similar to ours (50'000 words from the Frankfurter Rundschau plus 25'000 words from the Stuttgarter Zeitung). (Teufel et al., 1996) report on an error rate of only 3.0% for the TreeTagger. It could be that they were using different training parameters, these are not listed in the paper. But more likely they were using a more complete lexicon. They report on only 240 lexicon gaps among the 13'416 test tokens.

### 2.2 Training the Brill-Tagger

In parallel with the TreeTagger we trained the Brill-Tagger with our training corpus using the following parameter settings. Since we had some experience with training the Brill-Tagger we set the parameters slightly different from the Brill’s suggestions:

1. The threshold for the best found lexical rule was set to 2. The learner terminates when the score of the best found rule drops below this threshold. (Brill suggests 4 for a training corpus of 50K-100K words.)
2. The threshold for the best found contextual rule was set to 1. The learner terminates when the score of the best found rule drops below this threshold. (Brill suggests 3 for a training corpus of 50K-100K words.)
3. The bigram restriction value was set to 500. This tells the rule learner to only use bigram contexts where one of the two words is among the 500 most frequent words. A higher number will increase the accuracy at the cost of further increasing the training time. (Brill suggests 300.)

Training this tagger takes much longer than training the TreeTagger. Our training step took around 30 hours (!!) on a Sun Ultra-Sparc workstation. It resulted in:

1. a fullform lexicon with 14’147 entries (212 kByte)
2. a lexical-rules file with 378 rules (9 kByte)
3. a context-rules file with 329 rules (8 kByte)
4. a bigram list with 42’279 entries (609 kByte)

Using the tagger with this training output to tag the test corpus resulted in an error rate of 5.25%. Table 2 gives an overview of the errors.

---

3The suggestions for the tagging parameters of the Brill-Tagger are given in the README file that is distributed with the tagger.
Table 2: Error statistics of the Brill-Tagger

| ambiguity | tokens | in % | correct | in % | LE | in % | DE | in % |
|-----------|--------|------|---------|------|----|------|----|------|
| 0         | 1342   | 15.10| 1094    | 81.52| 248| 18.48| 0  | 0.00 |
| 1         | 5401   | 60.77| 5330    | 98.69| 71 | 1.31 | 0  | 0.00 |
| 2         | 993    | 11.17| 906     | 91.24| 3  | 0.30 | 84 | 8.46 |
| 3         | 795    | 8.95 | 758     | 95.35| 0  | 0.00 | 37 | 4.65 |
| 4         | 260    | 2.93 | 245     | 94.23| 0  | 0.00 | 15 | 5.77 |
| 5         | 96     | 1.08 | 87      | 90.62| 0  | 0.00 | 9  | 9.38 |
| total     | 8887   | 100.00| 8420   | 94.75| 322| 3.62 | 145| 1.63 |

It is striking that the overall result is very similar to the TreeTagger. A closer look reveals interesting differences. The TreeTagger is clearly better than the Brill-Tagger in dealing with unknown words (i.e., tokens not in the lexicon). There, the TreeTagger reaches 84.05% correct assignments which is 2.5% better than the Brill-Tagger. On the opposite side of the ambiguity spectrum the Brill-Tagger is superior to the TreeTagger in disambiguating between highly ambiguous tokens. For 4-way ambiguous tokens it reaches 94.23% correct assignments (a plus of 1.9% over the TreeTagger) and even for 5-way ambiguous tokens it still reaches 90.62% correct tags which is 4.1% better than the TreeTagger.

2.3 Error comparison

We then compared the types of errors made by both taggers. An error type is defined by the tuple (correct tag, tagger tag), where correct tag is the manually assigned tag and tagger tag is the automatically assigned tag. Both taggers produce about the same number of error types (132 for the TreeTagger and 131 for the Brill-Tagger). Table 3 lists the most frequent error types for both taggers. The biggest problem for both taggers is the distinction between proper nouns (NE) and common nouns (NN). This corresponds with the findings in [Teufel et al., 1996]. The distribution of proper and common nouns is very similar in German and is therefore difficult to distinguish by the taggers.

er wollte auch Weber/NN?/NE? einstellen

The second biggest problem results from the distinction between different forms of full verbs: finite verbs (VVFIN), infinite verbs (VVINF), and past participle verbs (VVPP). This problem is caused by the limited ‘window size’ of both taggers. The TreeTagger uses trigrams for its estimations, and the Brill-Tagger can base its decisions on up to three tokens to the right and to the left. This is rather limited if we consider the possible distance between the finite verb (in second position) and the rest of the verb group (in sentence final position) in German main clauses. In addition, the taggers cannot distinguish between main and subordinate clause structure.

... weil wir die Probleme schon kennen/VVFIN. Wir sollten die Probleme schon kennen/VVINF.

A third frequent error type arises between verb forms and adjectives (ADJA: adjective used as an attribute, inflected form; ADJD: adjective in predicative use, typically uninflected form). It might be surprising that the Brill-Tagger has so much difficulty to tell apart a finite verb and an inflected adjective (19 errors). But this can be explained by looking at the lexical rules learned by this tagger. These rules are used by the Brill-Tagger to guess a tag for unknown words (Brill, 1994). And the first lexical rule learned from our training corpus says that a word form ending in the letter e should be treated as an adjective (ADJA). Of course this assignment can be overridden by other lexical rules or contextual rules, but these obviously miss some 19 cases.

On the other hand it is surprising that the TreeTagger gets mixed up 8 times by past participle modal verbs (VMPP) which should be digit-sequence cardinal numbers (CARDNUM). There are 10 additional cases where a digit-sequence cardinal number was interpreted as some other tag by the TreeTagger. But there
are only 3 similar errors for the Brill-Tagger since its lexical rules are well suited to recognize unknown digit-sequence numbers.

3 Using an external lexicon

Let us sum up the results of the above comparison and see if we can improve tagging accuracy by using an external lexicon. The above comparison showed that:

1. The Brill-Tagger is better in recognizing special symbol items such as digit-sequence cardinal numbers, and it is better in disambiguating tokens which are many-ways ambiguous in the lexicon.

2. The TreeTagger is better in dealing with unknown word forms.

At first sight it seems easiest to improve the Brill-Tagger by reducing its unknown word problem. We employed the Gertwol system (Oy, 1994) a wide-coverage morphological analyzer to fill up the tagger lexicon before tagging starts. That means we extracted all unknown word forms from the test corpus and had Gertwol analyse them. From the 1342 unknown tokens we get 1309 types which we feed to Gertwol. Gertwol is able to analyse 1205 of these types. Gertwol’s output is mapped to the respective tags, and every word form with all possible tags is added temporarily to the tagger lexicon. In this way the tagger starts tagging the test corpus with an almost complete lexicon. The remaining lexicon gaps are the few words Gertwol cannot analyse. In our test corpus 109 tokens remain unanalysed.

Our experiments showed a slight improvement in accuracy (about 0.5%), but by far not as much as we had expected. The alternative of filling up the tagger lexicon by training over the whole corpus resulted in an improvement of around 3.5%, an excellent tagger accuracy of more than 98%. Note that we only used the lexicon filled in this way but the rules as learned from the training corpus alone. But, of course, it is an unrealistic scenario to know in advance (i.e., during tagger training) the text to be tagged.

The difference between using a large external ‘lexicon’ such as Gertwol and using the internal vocabulary is due to two facts. First, Gertwol increases the average ambiguity of tokens since it gives every possible tag for a word form. The internal vocabulary will only provide the tag occurring in the corpus. Second, in case of multiple tags for a word form the Brill-Tagger needs to know the most likely tag. This is very important for the Brill-Tagger algorithm. But Gertwol gives all possible tags in an arbitrary order. One solution is to sort Gertwol’s output according to overall tag probabilities. These can be computed from the frequencies of every tag in the training corpus irrespective of the word form. Using these rough probabilities improved the results in our experiments by about 0.2%. This means that the best result for combining Gertwol with the Brill-Tagger is at 95.45% accuracy.

In almost the same way we can use the external lexicon with the TreeTagger. We add all

| Number | Correct Tag | Tagger Tag | Number | Correct Tag | Tagger Tag |
|--------|-------------|------------|--------|-------------|------------|
| 48     | NE          | NN         | 54     | NE          | NN         |
| 21     | VVINF       | VVFFIN     | 31     | NN          | NE         |
| 20     | NN          | NE         | 19     | VVFIN       | VVINF      |
| 17     | VVFIN       | VVINF      | 19     | VVFIN       | ADJA       |
| 10     | VVPP        | VVFIN      | 17     | VVFIN       | VVFIN      |
| 10     | VVFIN       | VVPP       | 15     | VVPP        | VVFIN      |
| 8      | CARDNUM     | VMPP       | 11     | VVPP        | ADJD       |
| 7      | ADJD        | VVFIN      | 11     | ADJD        | VVFIN      |
| 7      | ADJD        | ADV        | 8      | VVINF       | ADJA       |

Table 3: Most frequent error types
types as analysed by Gertwol to the Treetagger’s lexicon. Then, unlike the Brill-Tagger, the Treetagger is retrained with the same parameters and input files as above except for the extended lexicon. The Brill-Tagger loads its lexicon for every tagging process, and the lexicon can therefore be extended without retraining the tagger. The Treetagger, on the other hand, integrates the lexicon during training into its ‘output file’. It must therefore be retrained after each lexicon extension.

Extending the lexicon improves the Treetagger’s accuracy by around 1% to 96.29%. Table 4 gives the results for the Treetagger with the extended lexicon.

The recognition of the remaining unknown words is very low (66.06%), but this does not influence the result much since only 1.23% of all tokens are left unknown. Also the rate of disambiguation errors increases from 1.49% to 2.06%. But at the same time the rate of lexical error drops from 3.24% to 1.65%, which accounts for the noticeable increase in overall accuracy.

4 The best of both worlds?

In the previous sections we observed that the statistical tagger and the rule-based tagger show complementary strengths. Therefore we experimented with combining the statistical and the rule-based tagger in order to find out whether a combination would yield a result superior to any single tagger.

First, we tried to employ the Treetagger and the Brill-Tagger in this order. Tagging the test corpus now works in two steps. In step one, we tag the test corpus with the Treetagger. We then add all unknown word forms to the Brill-Tagger’s lexicon with the tags assigned by the Treetagger. In step two, we tag the test corpus with the Brill-Tagger. In this way we can increase the Brill-Tagger’s accuracy to 95.13%. But the desired effect of combining the strengths of both taggers in order to build one tagger that is better than either of the taggers alone was not achieved. The reason is that the wrong tags of the Treetagger were carried over to the Brill-Tagger (together with the correct tags) and all of the new lexical entries were on the ambiguity level one or two, so that the Brill-Tagger could not show its strength in disambiguation.

In a second round we reduced the export of wrong tags from the Treetagger to the Brill-Tagger. We made sure that on export all digit-sequence ordinal and cardinal numbers were assigned the correct tags. We used a regular expression to check each word form. In addition, we checked for all other unknown word forms if the tag assigned by the Treetagger was permitted by Gertwol (i.e. if the Treetagger tag was one of Gertwol’s tags). If so, the Treetagger tag was exported. If the Treetagger tag was not allowed by Gertwol, we checked how many tags Gertwol proposes. If Gertwol proposes exactly one tag this tag was exported, in all other cases no tag was exported. In this way we exported 1171 types to the Brill-Tagger’s lexicon and we obtained a tagging accuracy of 95.90%. The algorithm for selecting Treetagger tags was further modified in one little respect. If Gertwol did not analyse a word form and the Treetagger identified it as a proper noun (NE), then the tag was exported. We then export 1212 types and we obtain a tagging accuracy of 96.03%, which is still slightly worse than the Treetagger with the external lexicon.

Second, we tried to employ the taggers in the reverse order: Brill-Tagger first, and then the Treetagger, using the Brill-Tagger’s output. In this test we extended the Treetagger’s lexicon with the tags assigned by the Brill-Tagger and we extended the training corpus with the test corpus tagged by the Brill-Tagger. We retrained the Treetagger with the extended lexicon and the extended corpus. We then used the Treetagger to tag the test corpus, which resulted in 95.05% accuracy. This means that the combination of the taggers results in a worse result than the Treetagger by itself (95.27%).

From these tests we conclude that it is not possible to improve the tagging result by simply sequentialising the taggers. In order to exploit their respective strengths a more elaborate intertwining of their tagging strategies will be necessary.

5 Text type evaluation

So far, all our tests were performed over the same test corpus. We checked whether the general tendency will also carry over to other test corpora. Besides the corpus used for the above evaluation we have a second manually tagged
Table 4: Error statistics of the TreeTagger with an extended lexicon

| ambiguity | tokens in % | correct in % | LE in % | DE in % |
|-----------|-------------|--------------|---------|---------|
| 0         | 109  1.23   | 72 66.06     | 37 33.94| 0 0.00  |
| 1         | 6307 70.97  | 6209 98.45   | 98 1.55 | 0 0.00  |
| 2         | 1224 13.77  | 1119 91.42   | 10 0.82 | 95 7.76 |
| 3         | 852  9.59   | 805 94.48    | 2 0.23  | 45 5.28 |
| 4         | 296  3.33   | 266 89.86    | 0 0.00  | 30 10.14|
| 5         | 99   1.11   | 86 86.87     | 0 0.00  | 13 13.13|
| total     | 8887 100.00 | 8557 96.29   | 147 1.65| 183 2.06|

corpus consisting of texts about the administration at the University of Zurich (the university’s annual report; guidelines for student registration etc.). This corpus currently consists of 38'007 tokens. We have applied the taggers, trained as above on 7/8 of the ‘Frankfurter Rundschau’ corpus, to this corpus and compared the results. In this way we have a much larger test corpus but we have a higher rate of unknown words (10'646 tokens, 28.01%, are unknown). The TreeTagger resulted in an accuracy rate of 92.37%, whereas the Brill-Tagger showed an accuracy rate of 91.65%. These results correspond very well with the above findings. The figures are close to each other with a small advantage for the TreeTagger. It should be noted that the much lower accuracy rates compared to the test corpus are in part due to inconsistencies in tagging decisions. E.g. the word ‘Management’ was tagged as a regular noun (NN) in the training corpus but as foreign material (FM) in the University of Zurich test corpus.

6 Conclusions

We have compared a statistical and a rule-based tagger for German. It turned out that both taggers perform on the same general level, but the statistical tagger has an advantage of about 0.5% to 1%. A detailed analysis shows that the statistical tagger is better in dealing with unknown words than the rule-based tagger. It is also more robust in using an external lexicon, which resulted in the top tagging accuracy of 96.29%. The rule-based tagger is superior to the statistical tagger in disambiguating tokens that are many-ways ambiguous. But such tokens do not occur frequently enough to fully get equal with the statistical tagger. A sequential combination of both taggers in either order did not show any improvements in tagging accuracy.

The statistical tagger is easier to handle in that its training time is 3 magnitudes shorter than the rule-based tagger (minutes vs. days). But it has to be retrained after lexicon extension, which is not necessary with the rule-based tagger. The rule-based tagger has the additional advantage that rules (i.e. lexical and contextual rules) can be manually modified. As a side result our experiments show that a rule-based tagger that learns its rules like the Brill-Tagger does not match the results of the constraint grammar tagger (a manually built rule-based tagger) described in (Samuelsson and Voutilainen, 1997). That tagger is described as performing with an error rate of less than 2%. Constraint grammar rules are much more powerful than the rules used in the Brill-Tagger.
