1 Introduction

The notion of a tower of Rankin-Selberg integrals was introduced in [G-R]. To recall this notion, let $G$ be a reductive group defined over a global field $F$. Let $L^G$ denote the $L$ group of $G$. Let $\rho$ denote a finite dimensional irreducible representation of $L^G$. Given an irreducible generic cuspidal representation of $G(A)$, we let $L^S(\pi, \rho, s)$ denote the partial $L$ function associated with $\pi$ and $\rho$. Here $s$ is a complex variable and $A$ denotes the adele ring associated with $F$. If $\rho$ acts on the vector space $V$, we denote by $C[V]^{L^G}$ the symmetric algebra attached to the vector space $V$. Let $C[V]^{L^G}$ denote the $L^G$ invariant polynomials inside the symmetric algebra. As far as we know all examples of $L$ functions represented by a Rankin-Selberg integral are associated with representations $\rho$ such that $C[V]^{L^G}$ is a free algebra. A list of all such groups, representations and the degrees of the generators of the invariant polynomials are given in [K].

The basic observation in [G-R] is that there is some relation between the Eisenstein series one uses to construct the Rankin-Selberg integral and the number of generators of the invariant polynomials and their degrees. This relation is far from being clear and it is mainly based on observation of all known constructions of such integrals. To summarize in an unprecise manner, the relations are:

1) If $\rho_1$ and $\rho_2$ have the same number of generators with the same degrees, then in some cases the Rankin-Selberg integrals which represent the corresponding two $L$ functions, use the same Eisenstein series.
Suppose that the Eisenstein series one uses for a certain construction is defined over $H(A)$, where $H$ is a reductive group. Suppose that this Eisenstein series corresponds to an induced representation induced from a parabolic subgroup $P = MU$ of $H$. Here $M$ is the Levi part of $P$ and $U$ its unipotent radical. The group $M(C)$ acts on $U(C)$ by conjugation and one obtains this way $r$ irreducible finite dimensional representations of $M(C)$. Suppose that the corresponding Rankin-Selberg integral represents the $L$ function $L^S(\pi, \rho, s)$. Let $k$ denote the number of generators of $C[V]^L_G$, where we recall that we assume that $C[V]^L_G$ is free. Then the second observation that was pointed out in [G-R] is that $r \geq k$.

It should be clear that these two observations are based mainly on experience and we are not aware of precise theoretical reasons. We also want to mention that information on $L$ functions $L^S(\pi, \rho, s)$ where $\rho$ does not satisfy the above properties, can be obtained using other methods such as lifting theory.

In this paper we wish to point out two more observations that may shed some more light on the above relations. It will be convenient to first illustrate these observations by considering two examples.

Consider the following example of a tower given in [G-R]:

\begin{align*}
(a_1) & \quad G = GL_n \quad L^G = GL_n(C) \quad \rho = 2\varpi_1 \\
(a_2) & \quad G = GL_n \times GL_n \quad L^G = GL_n(C) \times GL_n(C) \quad \rho = \varpi_1 \times \varpi_1 \\
(a_3) & \quad G = GL_{2n} \quad L^G = GL_{2n}(C) \quad \rho = \varpi_2
\end{align*}

We recall the construction of the Rankin-Selberg integral which represents the $L$ function in case (a3). This integral was introduced in [J-S] and is given by

$$
\int_{Z(A)GL_n(F)\backslash GL_n(A)} \int_{Mat_n(A)\backslash Mat_n(A)} \varphi_\pi \left( \begin{pmatrix}
I & X \\
0 & I
\end{pmatrix}
\begin{pmatrix}
g \\
I
\end{pmatrix}
\right) E(g, s) \psi(trX) dX dg 
$$

(1)

Here $\varphi_\pi$ is a vector in the space of $\pi$ which is an irreducible cuspidal representation defined on $GL_{2n}(A)$, and $E(g, s)$ is an Eisenstein series defined on the group $GL_n(A)$. For more details see [J-S]. Let us show how the integral which represents the $L$ function given in (a2) can be derived from integral (1). First notice that $GL_n \times GL_n$ is a Levi part of a maximal parabolic subgroup $P$ of $GL_{2n}$. Now suppose we formally replace in (1) the cuspidal representation $\pi$ by the Eisenstein series $E_{\tau, \sigma}(g, \nu)$ associated with the induced representation $Ind_{P(A)}^{GL_{2n}(A)}(\tau \otimes \sigma)\delta_p$. Here $\tau$ and $\sigma$ are cuspidal representations defined on $GL_n(A)$ and $\nu$ is a complex variable. Of course the integral will not converge. However, if we ignore this issue, and formally unfold the Eisenstein series $E_{\tau, \sigma}(g, \nu)$, we are led to consider the space of double cosets $P\backslash GL_{2n}/GL_nX$. If we consider the open orbit contribution to the
integral, it is not hard to check that we obtain the integral
\[ \int_{Z(A)GL_n(F)\backslash GL_n(A)} \varphi_\tau(g)\varphi_\sigma(g)E(g,s)dg \] (2)
as inner integration. As is well known, integral (2) represents the tensor product
\[ L \text{-function of } \tau \times \sigma. \] In other words, this integral is the one which represents the
\[ L \text{-function described in case (a2).} \]
Furthermore, if one restricts the exterior square representation \( \varpi'_2 \) of \( GL_2(C) \) to
\( GL_n(C) \times GL_n(C) \), then one obtains \( \varpi'_2|_{GL_n \times GL_n} = (\varpi_1 \times \varpi_1) \oplus (\varpi_2 \times 1) \oplus (1 \times \varpi_2) \). From this we deduce the following. If we start with the representation \( \rho \) as defined in case (a3) and
restrict it to the \( L \) group of the Levi part then the representation \( \rho \) corresponding to case
(a2) occurs in the restriction. Moreover its the representation with the largest dimension
which occurs in the restriction.

The formal replacement of a cuspidal representation by an Eisenstein series and then
analyzing the contribution from the open orbit is one of the observations we wish to make.
It should be mentioned that this observation does not explain how to derive a global con-
struction that will represent the \( L \) function described in case (a1). We now consider the
second example of a tower as described in \[G-R\]. This tower consists of four members as
follows:

\begin{align*}
(b1) & \quad G = GL_2 \quad L^G = GL_2(C) \quad \rho = 4\varpi_1 \\
(b2) & \quad G = GL_3 \quad L^G = GL_3(C) \quad \rho = \varpi_1 + \varpi_2 \\
(b3) & \quad G = GSpin_7 \quad L^G = GSp_6(C) \quad \rho = \varpi_2 \\
(b4) & \quad G = F_4 \quad L^G = F_4(C) \quad \rho = \varpi_4
\end{align*}

The construction of Rankin-Selberg integrals for cases (b1), (b3) and (b4) was given in
[G-R]. The case (b2) was studied in [G1]. The integral which represents the \( L \) function
given in (b4) can be described as follows. Let \( \pi \) denote a generic cuspidal representation
defined on the group \( F_4(A) \). Let \( E(g,s) \) denote the degenerate Eisenstein series defined on
the exceptional group \( G_2(A) \) as described in section 1 in [G-R]. The global integral is
\[ \int_{G_2(F)\backslash G_2(A)} \int_{U(F)\backslash U(A)} \varphi_\pi(u g)E(g,s)\psi_U(u)du dg \] (3)
Here \( U \) is a certain unipotent subgroup of \( F_4 \) and \( \psi_U \) is an additive character defined on
the group \( U \). Observe that \( GSpin_7 \) is a Levi part of a maximal parabolic subgroup \( P \) of \( F_4 \).
Let \( \tau \) denote a generic cuspidal representation defined on the group \( GSpin_7 \). Let \( E_\tau(g,\nu) \)
denote the Eisenstein series defined on the group \( F_4(A) \) which is associated to the induced
representation \( Ind_{P(A)}^{F_4(A)} r_\delta \). If we formally replace in (3) the cuspidal representation \( \pi \) by
\( E_\tau(g, \nu) \), and then unfold this Eisenstein series, then we obtain from the open orbit

\[
\int_{G_2(F) \setminus G_2(\mathbb{A})} \varphi_\tau(g) E(g, s) dg
\]

(4)
as inner integration. As described in [G-R] section 4 this is precisely the global integral which represents the \( L \) function which is described in (b3). Further more, let \( Q \) denote the maximal parabolic subgroup of \( Spin_7 \) whose Levi part is \( GL_3 \). Let \( \sigma \) denote a cuspidal representation defined on the group \( GL_3(\mathbb{A}) \). Replace in (4) the cuspidal representation \( \tau \) by the Eisenstein series \( E_\sigma(g, \nu) \) which is associated with the induced representation \( Ind_{Q(\mathbb{A})}^{Spin_7(\mathbb{A})} \sigma \delta_Q^\nu \). Unfolding the integral we obtain from the open orbit

\[
\int_{SL_3(F) \setminus SL_3(\mathbb{A})} \varphi_\sigma(g) E(g, s) dg
\]

(5)
as inner integration. As described in [G1] this is precisely the global integral which represents the \( L \) function described in (b2).

As in the previous case we can restrict in each case the representations \( \rho \) to the \( L \) group of the Levi part. Suppose that \((0, 0, 0, 1)\) is the representation of \( F_4(\mathbb{C}) \) of dimension 26. This is the representation \( \rho \) obtained in case (b4). Restrict it to \( GSp_6(\mathbb{C}) \) which is the \( L \) group of \( GSpin_7 \). We obtain \( (0, 0, 0, 1)|_{C_3} = (0, 1, 0) + 2(1, 0, 0) \). Here \((0, 1, 0)\) is the second fundamental representation of \( GSp_6(\mathbb{C}) \) which has degree 14, and \((1, 0, 0)\) is the six dimensional standard representation. If we further restrict \( GSp_6(\mathbb{C}) \) to \( GL_3(\mathbb{C}) \) we obtain \( (0, 1, 0)|_{A_2} = (1, 1) + (1, 0) + (0, 1) \). Again, as in the first tower we can see that if we restrict \( \rho \) as defined in case (b4) we obtain the representation \( \rho \) as defined in case (b3) as the largest piece in the restriction. Similarly, if we restrict from case (b3) to (b2).

We mention again that this observation does not allow one to obtain the integrals for cases (a1) and (b1). The construction in these cases is more complicated and involves covering groups.

To summarize, the above examples suggests the following two points:

1) Suppose that we are given a Rankin-Selberg integral which we know how to unfold to an Eulerian integral with the Whittaker function defined on the cuspidal representations. Then replacing a cuspidal representation by an Eisenstein series and considering the contribution from the open orbit, sometimes yields a new Eulerian Rankin-Selberg integral. In fact, one can replace the cuspidal representation by various Eisenstein series. Experience indicates that most of the time one gets either zero, or an integral which does not unfold to a Whittaker integral. The second point is
2) Suppose that the Eulerian integral we start with represents an $L$ function which is associated to the finite dimensional irreducible representation $\rho$ of the complex group $L G$. Suppose that we replace a cuspidal representation, defined over the group $G(A)$, by an Eisenstein series induced from a cuspidal representation defined on the Levi part $M(A)$. Suppose that when we formally unfold the new integral, the contribution from the open orbit produces a new integral which is Eulerian with Whittaker functions. Then the new integral will represent the $L$ function associated with the largest irreducible representation which occurs in the restriction $\rho|_{L M}$.

In these notes we announce a construction of a new tower of Rankin-Selberg integrals. The tower we consider is the following

(c1) $G = GL_3 \times GL_2$ \hspace{1cm} $L G = GL_3(C) \times GL_2(C)$ \hspace{1cm} $\rho = 2 \varpi_1 \times \varpi_1$

(c2) $G = GL_3 \times GL_3 \times GL_2$ \hspace{1cm} $L G = GL_3(C) \times GL_3(C) \times GL_2(C)$ \hspace{1cm} $\rho = \varpi_1 \times \varpi_1 \times \varpi_1$

(c3) $G = GL_6 \times GL_2$ \hspace{1cm} $L G = GL_6(C) \times GL_2(C)$ \hspace{1cm} $\rho = \varpi_2 \times \varpi_1$

(c4) $G = E_6 \times GL_2$ \hspace{1cm} $L G = E_6(C) \times GL_2(C)$ \hspace{1cm} $\rho = \varpi_1 \times \varpi_1$

It follows from $[K]$ that in all these representations the $L G$ invariant algebra has one generator of degree 12. At this point we know a Rankin-Selberg construction for all three cases (c2) − (c4). In the next section we shall explain these constructions and show in an example how to derive one integral from the other. One can also check that restricting from one case to the other does indeed produce the right representation $\rho$ in each case.

It should be mentioned that all of these $L$-functions can be studied using the Langlands-Shahidi method as explained in $[S]$.

## 2 The Global Integrals

We start with the global construction which will correspond to case (c4), as explained in the introduction. Let $G$ denote the similitude exceptional group of type $E_6$, constructed exactly as in $[G2]$. To introduce the global integral we shall need to consider two small representations which we shall now define. First, let $\theta$ denote the minimal representation defined on $G(A)$. This representation was constructed and studied in $[G-R-S]$. The construction there is defined on the group $E_6$, however there are no problems to extend this definition to similitude groups. See $[G-H]$ for a similar definition for the similitude exceptional group $GE_7$. In this paper we shall denote a function in the space of this representation by $\theta(g)$. Another representation we will need for our construction was defined and studied in $[G-H]$ section 3. The representation constructed there was defined on the group $GSO_{10}(A)$. A similar definition holds for the
group $GSpin_{10}(A)$. This representation depends on a cuspidal representation $\tau$ defined on $GL_2(A)$. We shall denote a vector in this space by $\theta_\tau(h)$ where $h \in GSpin_{10}(A)$. We briefly recall the definition. Let $R$ denote the parabolic subgroup of $GSpin_{10}$ whose Levi part is $GL_3 \times GSpin_4$. Let $\epsilon(\tau) = \tau \otimes \tau$ and let $\mu(\tau)$ denote the symmetric square lift of $\tau$ to $GL_3$ as constructed in [Ge-J]. Let $E(\tau, h, s)$ denote the Eisenstein series defined on $GSpin_{10}(A)$ associated with the induced representation $Ind_{R(A)}^{GSpin_{10}(A)}(\mu(\tau) \otimes \epsilon(\tau)) \delta_R^s$. It is not hard to check that this Eisenstein series has a unique simple pole, and we denote the residue representation by $\theta_\tau$.

Using this last representation, we shall now construct the Eisenstein series we use in our global construction. Let $P$ denote the maximal standard parabolic subgroup of $G$ whose Levi part contains all the simple roots except $\alpha_1$. This Levi part is essentially $GSpin_{10}$. Let $E_\tau(g, s)$ denote the Eisenstein series defined on $G(A)$ which is associated to the induced representation $Ind_G^{P(A)}(\theta_\tau \delta_P^s)$. Let $\pi$ denote a generic cuspidal representation defined on $G(A)$. We shall assume that $\pi$ has a trivial central character. Consider the global integral

$$\int_{Z(A)G(F) \backslash G(A)} \varphi_\pi(g) \theta_\tau(g) E_\tau(g, s) dg (6)$$

Here $Z$ denotes the center of $G$ and $\varphi_\pi$ is a vector in the space of $\pi$. This integral represents the $L$ function corresponding to case (c4).

Let us show how to obtain the Rankin-Selberg integral which will represent case (c3) as denoted in the introduction. Let $Q$ denote the maximal parabolic subgroup of $G$ whose Levi part is $M = GL_1 \times GL_6$. Let $\sigma$ denote a cuspidal representation of $GL_6(A)$ with trivial central character. Let $E_\sigma(g, \nu)$ denote the Eisenstein series defined on $G(A)$ associated with the induced representation $Ind_{Q(A)}^{G(A)}(\sigma \delta_Q^\nu)$. In (6) we replace the function $\varphi_\pi(g)$ by $E_\sigma(g, \nu)$. Even though the integral does not converge, we formally unfold the Eisenstein series $E_\sigma(g, \nu)$ to obtain

$$\int_{Z(A)M(F)U(F) \backslash G(A)} f_\sigma(g, \nu) \theta_\tau(g) E_\tau(g, s) dg (7)$$

Here $U$ is the unipotent radical of $Q$ and $f_\sigma(g, \nu)$ defines a section in the corresponding induced representation. Recall that $U$ has a structure of a Heisenberg group with 21 variables. Let $x_{122321}(r)$ denote the one dimensional unipotent subgroup $U$ which is the center of $U$. Here, and henceforth we shall use the notations for various roots of the group $G$ as defined in [G2]. We expand $\theta_\tau(g)$ along the center of $U$. That is, we expand it along the unipotent
group generated by $x_{122321}(r)$ with points in $F \backslash A$. The group $M(F)$ acts on this expansion with two orbits. Ignoring the trivial orbit, we obtain the contribution
\[
\int_{Z(A)H(F)U(F) \backslash G(A) F \backslash A} \int \theta(x_{122321}(r_1)g)\psi(r_1)dr_1f_{\sigma}(g,\nu)E_{\tau}(g, s)dg
\]
(8)

Here $H$ is the stabilizer inside $M$ of the character $\psi$. One can check that $H = \{ g \in GL_6 : \det g \text{ is a square} \}$. Factoring the integration over $H$ and over the center of $U$ we obtain after a change of variables, the integral
\[
\int_{Z(A)H(F)\backslash H(A) U(F) \backslash U(A) (F \backslash A)^2} \int \varphi_{\sigma}(h)\theta(ux_{122321}(r_1)h)E_{\tau}(ux_{122321}(r_2)h, s)\psi(r_1 - r_2)dr_1dr_2dh
\]
(9)
as inner integration. Here $\varphi_{\sigma}$ is a vector in the space of the cuspidal representation $\sigma$. Notice that this integral converges absolutely. This is our candidate for the Rankin-Selberg integral which will represent case (c3).

We can further continue and replace $\sigma$ by an Eisenstein series. Indeed let $\pi_1$ and $\pi_2$ denote two cuspidal representations of $GL_3(A)$. Let $L$ denote the parabolic subgroup of $GL_6$ whose Levi part is $GL_3 \times GL_3$. Let $E_{\pi_1,\pi_2}(x, \nu)$ denote the Eisenstein series associated with the induced representation $\text{Ind}_{L(A)}^{GL_6(A)}(\pi_1 \otimes \pi_2)\delta^r_L$. Replacing in (8) the cuspidal representation $\sigma$ by this Eisenstein series (again, this is a formal process, since the integral does not converge) and performing certain Fourier expansions, one obtains the integral
\[
\int_{Z(A)H(F)\backslash H(A) V(F) \backslash V(A) (F \backslash A)^3} \int \varphi_{\pi_1,\pi_2}(h)\theta(x_{010000}(r_1)ux_{112321}(r_2)x_{122321}(r_3)h)\times
\]
\[
E_{\tau}(x_{010000}(r_1)vh, s)\psi(r_1 + r_2)dr_1dvdh
\]
(10)as inner integration. Here $\varphi_{\pi_1,\pi_2}$ is a vector in the space of $\pi_1 \otimes \pi_2$. We also have $H = \{(g_1, g_2) \in GL_3 \times GL_3 : \det g_1 = \det g_2 \}$ and the group $V$ is the standard unipotent radical of the maximal parabolic subgroup of $G$ whose Levi part is $GL_3 \times GL_3 \times GL_2$. This is the integral which represents the case (c2).

At this point we unfolded all these three integrals and established that they are indeed Eulerian. This we achieved by obtaining the Whittaker function of each of the cuspidal representations involved in the integral. As always, with these type of integrals, the unfolding process is long and tedious but quite straightforward. The next step is to compute the unramified local integrals. So far we have performed some of the calculations which indicate that our integrals do represent the $L$ functions in question. It is not yet clear to us how
complicated will be the decomposition of the symmetric algebras in the various cases. It will also be interesting to study the possible poles of these \( L \) functions. This will be accomplished by understanding the poles of the Eisenstein series we use in all these cases.

We are also interested in finding the Rankin-Selberg integral which represents case \((c1)\). Past experience indicates that some of the representations involved should be defined on a covering group. So far we don’t know how to do it.

We summarize

**Theorem:** Integrals (6), (9) and (10) are Eulerian. Each of these three integrals unfolds to the Whittaker function defined on each cuspidal representation which appears in the integral. Integral (6) represents the partial \( L \) function \( L^S(\pi \times \tau, St \times St, s) \) where \( St \times St \) corresponds to the standard representation of \( L^G \times GL_2(\mathbb{C}) \). Integral (9) represents \( L^S(\sigma \times \tau, \wedge^2 \times St, s) \) where \( \wedge^2 \) is the exterior square representation of \( GL_6(\mathbb{C}) \), and integral (10) represents \( L^S(\pi_1 \times \pi_2 \times \tau, St \times St \times St, s) \).
