A Dynamic Programming Algorithm for the Segmentation of Greek Texts

Pavlina Fragkou

In this paper we introduce a dynamic programming algorithm to perform linear text segmentation by global minimization of a segmentation cost function which consists of: (a) within-segment word similarity and (b) prior information about segment length. The evaluation of the segmentation accuracy of the algorithm on a text collection consisting of Greek texts showed that the algorithm achieves high segmentation accuracy and appears to be very innovating and promising.

**Keywords:** Text Segmentation, Document Retrieval, Information Retrieval, Machine Learning.

1. Introduction

Text segmentation is an important problem in information retrieval. Its goal is the division of a text into homogeneous ('lexically coherent') segments, i.e. segments exhibiting the following properties: (a) each segment deals with a particular subject and (b) contiguous segments deal with different subjects. Those segments can be retrieved from a large database of unformatted (or loosely formatted) text as being relevant to a query.

This paper presents a dynamic programming algorithm which performs linear segmentation by global minimization of a segmentation cost. The segmentation cost is defined by a function consisting of two factors: (a) within-segment word similarity and (b) prior information about segment length. Our algorithm has the advantage that it can be applied to either large texts - to segment them into their constituent parts (e.g. to segment an article into sections) - or to a stream of independent, concatenated texts (e.g. to segment a transcript of news into separate stories).

---

1As opposed to hierarchical segmentation (Yaari (1997))
For the calculation of the segment homogeneity (or alternatively heterogeneity) of a text, several segmentation algorithms using a variety of criteria have been proposed in the literature. Some of those use linguistic criteria such as cue phrases, punctuation marks, prosodic features, reference, syntax and lexical attraction (Beeferman et al. 1997, Hirschberg & Litman 1993, Passoneau & Litman 1993). Others, following Halliday and Hasan’s theory (Halliday & Hasan 1976), utilize statistical similarity measures such as word cooccurrence. For example the linear discourse segmentation algorithm proposed by Morris and Hirst (Morris & Hirst 1991) is based on lexical cohesion relations determined by use of Roget’s thesaurus (Roget 1977). In the same direction Kozima’s algorithm (Kozima 1993, Kozima & Furugori 1993) computes the semantic similarity between words using a semantic network constructed from a subset of the Longman Dictionary of Contemporary English. Local minima of the similarity scores correspond to the positions of topic boundaries in the text.

Youmans (Youmans 1991) and later Hearst (Hearst & Plaunt 1993, Hearst 1994) focused on the similarity between adjacent parts of a text. They used a sliding window of text and plotted the number of first-used words in the window as a function of the window’s position within the text. In this plot, segment boundaries correspond to deep valleys followed by sharp upturns. Kan (Kan et al. 1998) expanded the same idea by combining word-usage with visual layout information.

On the other hand, other researchers focused on the similarity between all parts of a text. A graphical representation of this similarity is a dotplot. Reynar (Reynar 1998; 1999) and Choi (Choi 2000, Choi et al. 2001) used dotplots in conjunction with divisive clustering (which can be seen as a form of approximate and local optimization) to perform linear text segmentation. A relevant work has been proposed by Yaari (Yaari 1997) who used divisive / agglomerative clustering to perform hierarchical segmentation. Another approach to clustering performs exact and global optimization by dynamic programming; this was used by Ponte and Croft (Ponte & Croft 1997, Xu & Croft 1996), Heinonen (Heinonen, O. 1998) and Utiyama and Isahara (Utiyama & Isahara 2001).

Finally, other researchers use probabilistic approaches to text segmentation including the use of Hidden Markov Models (Yamron et al. 1999, Blei & Moreno 2001). Also Beeferman (Beeferman et al. 1997) calculated the probability distribution on segment boundaries by utilizing word usage statistics, cue words and several other features.

2. The algorithm
2.1. Representation

Suppose that a text contains $T$ sentences and its vocabulary contains $L$ distinct words (e.g. words that are not included in the stop list, otherwise most sentences would be similar to most others). This text can be represented by a $T \times L$ matrix
F defined as follows: for \( t = 1, 2, ..., T \) and \( l = 1, 2, ..., L \) we set
\[
F_{t,l} = \begin{cases} 
1 & \text{iff } l\text{-th word is in } t\text{-th sentence} \\
0 & \text{else.}
\end{cases}
\]

The sentence similarity matrix \( D \) of the text is a \( T \times T \) matrix where for \( s, t = 1, 2, ..., T \) we set
\[
D_{s,t} = \begin{cases} 
1 & \text{if } \sum_{l=1}^{L} F_{s,l}F_{t,l} > 0; \\
0 & \text{if } \sum_{l=1}^{L} F_{s,l}F_{t,l} = 0.
\end{cases}
\]
This means that \( D_{s,t} = 1 \) if the \( s\)-th and \( t\)-th sentence have at least one word in common. Every part of the original text corresponds to a submatrix of \( D \). It is expected that submatrices which correspond to actual segments will have many sentences with words in common, thus will contain many ‘ones’. In Figure 1 we give a dotplot of a matrix corresponding to a 91-sentences text. ‘Ones’ are plotted as black squares and ‘zeros’ as white squares. Further justification for the use of this similarity matrix and graphical representation can be found in Petridis et al. (2001), Kehagias, A et al. (2002), Reynar (1998; 1999), Choi (2000) and Choi et al. (2001).

We make the assumption that segment boundaries always occur at the end of sentences. A segmentation of a text is a partition of the set \( \{1, 2, ..., T\} \) into \( K \) subsets (i.e. segments, where \( K \) is a variable number) of the form \( \{1, 2, ..., t_1\}, \{t_1+1, t_1+2, ..., t_2\}, ..., \{t_{K-1}+1, t_{K-1}+2, ..., T\} \) and can be represented by a variable length vector \( t = (t_0, t_1, ..., t_K) \), where \( t_0, t_1, ..., t_K \) are the segment boundaries corresponding to the last sentence of each subset.

2.2. Dynamic Programming

Dynamic programming as a method guarantees the optimality of the result with respect to the input and the parameters. Following the approach of Heinonen (Heinonen, O. 1998) we use a dynamic programming algorithm which decides the locations of the segment boundaries by calculating the globally optimal splitting \( t \) on the basis of a similarity matrix (or a curve), a preferred fragment length and a cost function defined. Given a similarity matrix \( D \) and the parameters \( \mu, \sigma, r \) and \( \gamma \) (the role of each of which will be described in the sequel) the dynamic programming algorithm tries to minimize a segmentation cost function \( J(t; \mu, \sigma, r, \gamma) \) with respect to \( t \) (here \( t \) is the independent variable which is actually a vector specifying the boundary position of each segment and the number of segments \( K \) while \( \mu, \sigma, r, \gamma \) are parameters) which is defined in equation (1).

\[
J(t; \mu, \sigma, r, \gamma) = \sum_{k=1}^{K} \gamma \cdot \frac{(t_k-t_{k-1}-\mu)^2}{2\sigma^2} + (1 - \gamma) \cdot \frac{\sum_{i=t_{k-1}+1}^{t_k} \sum_{j=t_{k-1}+1}^{t_k} D_{i,j}}{(t_k-t_{k-1})^2}
\]
(1)
Hence the sum of the costs of the $K$ segments constitutes the total segmentation cost; the cost of each segment is the sum of the following two terms (with their relative importance weighted by the parameter $\gamma$):

1. The term $\frac{(t_k-t_{k-1})^2}{2\sigma^2}$ corresponds to the length information measured as the deviation from the average segment length. In this sense, $\mu$ and $\sigma$ can be considered as the mean and standard deviation of segment length measured either on the basis of words or on the basis of sentences appearing in the text’s segments and can be estimated from training data.

2. The term $\frac{\sum_{i=k-1}^{k-1} \sum_{j=k-1}^{k-1} D_{s,t}^2}{(t_k-t_{k-1})^r}$ corresponds to (word) similarity between sentences. The numerator of this term is the total number of ‘ones’ in the $D$ submatrix corresponding to the $k$-th segment. In the case where the parameter $r$ is equal to 2, $(t_k-t_{k-1})^r$ corresponds to the area of submatrix and the above fraction corresponds to ‘segment density’. A ‘generalized density’ is obtained when $r \neq 2$ and enables us to control the degree of influence of the surface with regard to the ‘information’ (i.e. the number of ‘ones’) included in it. Strong intra-segment similarity (as measured by the number of words which are common between sentences belonging to the segment) is indicated by large values of $\frac{\sum_{i=k-1}^{k-1} \sum_{j=k-1}^{k-1} D_{s,t}^2}{(t_k-t_{k-1})^r}$, irrespective of the exact value of $r$.

Segments with high density and small deviation from average segment length (i.e. a small value of the corresponding $J(t; \mu, \sigma, r, \gamma)$) provide a ‘good’ segmentation vector $t$. The global minimum of $J(t; \mu, \sigma, r, \gamma)$ provides the optimal segmentation $\hat{t}$. It is worth mentioning that the optimal $\hat{t}$ specifies both the optimal number of segments $K$ and the optimal positions of the segment boundaries $t_0, t_1, ..., t_K$. In the sequel, our algorithm is presented in a form of pseudocode.

**Dynamic Programming Algorithm**

**Input:** The $T \times T$ similarity matrix $D$; the parameters $\mu$, $\sigma$, $r$, $\gamma$.

**Initialization**

For $t = 1, 2, ..T$

$\text{Sum} = 0$

For $s = 1, 2, ..., t - 1$

$\text{Sum} = \text{Sum} + D_{s,t}$

$S_{s+1,t} = \frac{\text{Sum}}{(t-s)}$

End

End

**Minimization**

$^2$Small in the algebraic sense: $J(t; \mu, \sigma, r, \gamma)$ can take both positive and negative values.
$C_0 = 0, Z_0 = 0$

For $t = 1, 2, ..., T$

$C_t = \infty$

For $s = 1, 2, ..., t - 1$

If $C_s + S_{s,t} + \frac{(t-s-\mu)^2}{2 \sigma^2} \leq C_t$

$C_t = C_s - (1 - \gamma) S_{s+1,t} + \gamma \cdot \frac{(t-s-\mu)^2}{2 \sigma^2}$

$Z_t = s$

EndIf

End

End

BackTracking

$K = 0, s_K = T$

While $Z_{s_K} > 0$

$K = K + 1$

$s_K = Z_{s_K - 1}$

End

$K = K + 1, s_K = 0, \hat{t}_0 = 0$

For $k = 1, 2, ..., K$

$\hat{t}_k = s_K - k$

End

Output: The optimal segmentation vector $\hat{t} = (\hat{t}_0, \hat{t}_1, ..., \hat{t}_K)$.

3. Evaluation

3.1. Measures of Segmentation Accuracy

The performance of our algorithm was evaluated by three indices: Precision, Recall and Beeferman’s $P_k$ metric. Precision and Recall measure segmentation accuracy. For the segmentation task, Precision is defined as ‘the number of the estimated segment boundaries which are actual segment boundaries’ divided by ‘the number of the estimated segment boundaries’. On the other hand, Recall is defined as ‘the number of the estimated segment boundaries which are actual segment boundaries’ divided by ‘the number of the true segment boundaries’. High segmentation accuracy is indicated by high values of both Precision and Recall. However, these two indices have some shortcomings. First, high Precision can be obtained at the expense of low Recall and conversely. Additionally, those two indices penalize equally every inaccurately estimated segment boundary whether it is near or far from a true segment boundary.

An alternative measure $P_k$ which overcomes the shortcomings of Precision and Recall and measures segmentation inaccuracy was introduced recently by Beeferman et al. (Beeferman et al. 1997). Intuitively, $P_k$ measures the proportion of ‘sentences which are wrongly predicted to belong to the same segment (while
actually they belong in different segments)’ or ‘sentences which are wrongly predicted to belong to different segments (while actually they belong to the same segment)’. $P_k$ is a measure of how well the true and hypothetical segmentations agree (with a low value of $P_k$ indicating high accuracy (Beeferman et al. 1997)). $P_k$ penalizes near-boundary errors less than far-boundary errors. Hence $P_k$ evaluates segmentation accuracy more accurately than Precision and Recall.

3.2. Experiments

For the experiments, we use a text collection compiled from a corpus comprising of text downloaded from the website http://tovima.dolnet.gr of the newspaper entitled ‘To Vima’. This newspaper contains articles belonging to one of the following categories: 1) Editorial, diaries, reportage, politics, international affairs, sport reviews 2) cultural supplement 3) Review magazine 4) Business, finance 5) Personal Finance 6) Issue of the week 7) Book review supplement 8) Art review supplement 9) Travel supplement. Stamatatos et al. (2001) constructed a corpus collecting texts from supplement no. 2) which includes essays on science, culture, history etc. They selected 10 authors from the above set without taking any special criteria into account. Then 30 texts of each author were downloaded from the website of the newspaper as shown in the table below:

| Author  | Thematic Area       |
|---------|---------------------|
| Alachiotis | Biology         |
| Babiniotis | Linguistics      |
| Dertilis | History,Society    |
| Kiosse  | Archeology         |
| Liakos  | History,Society    |
| Maronitis | Culture,Society |
| Ploritis | Culture,History    |
| Tassios | Technology,Society |
| Tsukalas | International Affairs |
| Vokos   | Philosophy         |

Table 1: List of Authors and Thematic Areas dealt by each of those.

No manual text preprocessing nor text sampling was performed aside from removing unnecessary heading irrelevant to the text itself. All the downloaded texts were taken from the issues published from 1997 till early 1999 in order to minimize the potential change of the personal style of an author over time. Further details can be found in Stamatatos et al. (2001).

The preprocessing of the above texts was made using the morphosyntactic tagger (better known as part-of-speech tagger) developed by G. Orphanos (Orphanos & Christodoulakis 1999, Orphanos & Tsalidis 1999). The aforementioned tagger
is a POS tagger for modern Greek (a high inflectional language) which is based on a Lexicon capable of assigning full morphosyntactic attributes (i.e. POS, Number, Gender, Tense, Voice, Mood and Lemma) to 876,000 Greek word forms. This Lexicon was used to build a tagged corpus capable of identifying the behavior of all POS ambiguity schemes present in Modern Greek (e.g. Pronoun-Clitic-Article, Pronoun-Clitic, Adjective-Adverb, Verb-Noun, etc) as well as the characteristics of unknown words. This corpus was used for the induction of decision trees, which along with the Lexicon are integrated into a robust POS tagger for Modern Greek texts.

The tagger architecture consists of three parts: the Tokenizer, the Lexicon and finally the Disambiguator and Guesser. Raw text passes through the Tokenizer, where it is converted to a stream of tokens. Non-word tokens (e.g. punctuation marks, numbers, dates etc.) are resolved by the Tokenizer and receive a tag corresponding to their category. Word tokens are looked up in the Lexicon and those found receive one or more tags. Words with more than one tags and those not found in the Lexicon pass through the Disambiguator/Guesser, where the contextually appropriate tag is decided.

The Disambiguator/Guesser is a ‘forest’ of decision trees, one tree for each ambiguity scheme present in Modern Greek and one tree for unknown guessing. When a word with two or more tags appears, its ambiguity scheme is identified. Then, the corresponding decision tree, is selected, which is traversed according to the values of the morphosyntactic features extracted from contextual tags. This traversal returns the contextually appropriate POS along with its corresponding lemma. The ambiguity is resolved by eliminating the tag(s) with different POS than the one returned by the decision tree. The POS of an unknown word is guessed by traversing the decision tree for unknown words, which examines contextual features along with the word ending and capitalization and returns an open class POS and the corresponding lemma.

3.2.1. Preprocessing

For the experiments we use the texts taken from the collection compiled from the corpus of the newspaper ‘To Vima’. Each of the 300 texts of the collection of articles compiled from this newspaper is preprocessed using the POS tagger developed by G. Orphanos. More specifically, every word in the text was substituted by its lemma, determined by the tagger. Punctuation marks, numbers and all words were removed except from words that are either nouns, verbs, adjectives or adverbs. For those words that their lemma was not determined by the tagger, due to the fact that those words were not contained in the Lexicon used for the creation of the tagger, no substitution was made and the words were used as they were. The only information that was kept was the end of each sentence appearing in each text. We next present two suites of experiments. The difference between those suites lies in the length of the created segments and the number of authors
used for the creation of the texts to segment, where each text being a concatenation of ten text segments.

### 3.2.2. First suite of experiments

In the first suite of experiments, our collection consists of 6 datasets: Set0, ..., Set5. The difference between those datasets lies in the number of authors used for the generation of the texts to segment and consequently the number of texts used from the collection. The table below contains the aforementioned information.

| Dataset | Authors | No. of texts per dataset |
|---------|---------|--------------------------|
| 0       | Kiosse, Alachiotis | 60                        |
| 1       | Kiosse, Maronitis  | 60                        |
| 2       | Kiosse, Alachiotis, Maronitis | 90                   |
| 3       | Kiosse, Alachiotis, Maronitis, Ploritis | 120             |
| 4       | Kiosse, Alachiotis, Maronitis, Ploritis, Vokos | 150            |
| 5       | All Authors      | 300                       |

**Table 2:**
List of the datasets compiled in the 1st suite of experiments and the number of the author’s texts used for each of those.

For each of the above datasets, we constructed four subsets. The difference between those subsets lies in the range of the sentences appearing in each segment for every text. If $a$ and $b$ correspond to the lower and higher values of sentences consisting each segment, we have used four different pairs: $(3,11)$, $(3,5)$, $(6,8)$ and $(9,11)$. In every dataset, before generating any of the texts to segment, each of which contains 10 segments, we selected the authors, whose texts will be used for this generation. If $X$ is the number of authors contributing to the generation of the dataset, for all datasets, each text is generating according to the following procedure (which guarantees that each text contains ten segments):

*For the $j$-th out of 10 segments (e.g. $j = 1, 2, ..., 10$) of the generated text:*

1. Select randomly a number $i \in \{1, ..., X\}$ corresponding to an author among those contributing to the generation of the dataset.

2. Select randomly a number $k \in \{1, 2, ..., 30\}$ corresponding to the texts belonging to the $i$-th author.

3. Select randomly a number $l \in \{a, ..., b\}$ corresponding to the number of consecutive sentences extracted from the $k$-th text (starting from the first sentence). Those sentences constitutes the generated segment.

For every subset, using the procedure described above, we generated 50 texts. As it was mentioned before, our algorithm uses four parameters $\mu, \sigma, \gamma$ and $r$, 
A Dynamic Programming Algorithm for the Segmentation of Greek Texts

57

where $\mu$ and $\sigma$ can be interpreted as the average and standard deviation of segment length; it is not immediately obvious how to calculate the optimal values for each of the parameters. A procedure for determining appropriate values of $\mu, \sigma, \gamma$ and $r$ was introduced using training data and a parameter validation procedure. Then our algorithm is evaluated on (previously unseen) test data. More specifically, for each of the datasets Set0,..., Set5 and each of their subsets we perform the procedure described in the sequel:

1. Half of the texts in the dataset are chosen randomly to be used as training texts; the rest of the samples are set aside to be used as test texts.

2. Appropriate $\mu$ and $\sigma$ values are determined using all the training texts and the standard statistical estimators.

3. Parameter $\gamma$ is set to take the values 0.00, 0.01, 0.02, ... , 0.09, 0.1, 0.2, 0.3, ... , 1.0 and $r$ to take the values 0.33, 0.5, 0.66, 1. This yields $20 \times 4 = 80$ possible combinations of $\gamma$ and $r$ values. Appropriate $\gamma$ and $r$ values are determined by running the segmentation algorithm on all the training texts with the 80 possible combinations of $\gamma$ and $r$ values; the one that yields the minimum $P_k$ value is considered to be the optimal ($\gamma$, $r$) combination.

4. The algorithm is applied to the test texts using previously estimated $\gamma$, $r$, $\mu$ and $\sigma$ values.

An idea of the influence of $\gamma$ and $r$ on $P_k$ on the first suite of experiments can be observed in Figures 2-5 (corresponding to subsets '3-11', '3-5', '6-8' and '9-11' of Set5). In those figures $Exp\ I$ refers to the first suite of experiments.

The above procedure is repeated five times for each of the six datasets and the resulting values of Precision, Recall and $P_k$ are averaged. The performance of our algorithm (as obtained by the validated parameter values) is presented in Table 3.

3.2.3. Second Suite of experiments

In the second suite of experiments we used the same collection of texts compiled from the corpus of the newspaper ‘To Vima’. The difference between those two suites lies in the way of generating the texts used for training and for testing. In this suite of experiments, we used all the available (300) texts of the collection of the Greek corpus, which means all the available authors. We constructed a single dataset containing 200 texts. Half of them were used for training while the rest of them were used for testing. Each of the aforementioned texts was generated according to the following procedure (which guarantees that each text contains 10 segments):

For the $j$-th out of 10 segments (e.g. $j = 1, 2, ..., 10$) of the generated text:
(I) Select randomly a number \( i \in \{ 1, \ldots, 10 \} \) corresponding to an author among the 10 contributing to the generation of the dataset.

(II) Select randomly a number \( k \in \{ 1, 2, \ldots, 30 \} \) corresponding to the texts belonging to the \( i \)-th author. The selected text is read and scanned in order to determine the number of paragraphs that consists it. If \( Z \) is the number of paragraphs that consists it then:

(III) Select randomly a number \( l \in \{ 1, \ldots, Z \} \) corresponding to the number of paragraphs appearing in the \( k \)-th text.

(IV) Select randomly a number \( m \in \{ 1, \ldots, Z-l \} \) corresponding to the "starting paragraph". Thus the segment contains all the paragraphs of the \( k \)-th text starting from paragraph \( m \) and ending at the paragraph \( m + l \).

| 1st suite of Experiments | (3,11) | (3,5) | (6,8) | (9,11) |
|--------------------------|--------|-------|-------|-------|
| Set0 Precision           | 70.65% | 86.82%| 96.44%| 93.33%|
| Set0 Recall              | 71.11% | 87.11%| 96.44%| 93.33%|
| Set0 Beeferman’s \( P_k \)| 14.04% | 6.20% | 0.82% | 0.84% |
| Set1 Precision           | 63.86% | 82.98%| 91.11%| 94.67%|
| Set1 Recall              | 67.11% | 83.56%| 91.11%| 94.67%|
| Set1 Beeferman’s \( P_k \)| 15.82% | 8.47% | 2.81% | 0.98% |
| Set2 Precision           | 71.14% | 90%   | 91.11%| 92.44%|
| Set2 Recall              | 60.89% | 89.78%| 91.11%| 92.44%|
| Set2 Beeferman’s \( P_k \)| 14.42% | 3.45% | 2.15% | 1.247%|
| Set3 Precision           | 59.99% | 84.44%| 86.22%| 91.11%|
| Set3 Recall              | 58.67% | 83.56%| 86.22%| 91.11%|
| Set3 Beeferman’s \( P_k \)| 17.93% | 7.36% | 3.28% | 1.45% |
| Set4 Precision           | 57.99% | 85%   | 88.89%| 91.11%|
| Set4 Recall              | 51.11% | 84.89%| 88.89%| 91.11%|
| Set4 Beeferman’s \( P_k \)| 17.38% | 6.76% | 2.65% | 1.39% |
| Set5 Precision           | 65.74% | 81.56%| 89.33%| 88.89%|
| Set5 Recall              | 61.78% | 81.78%| 89.33%| 88.89%|
| Set5 Beeferman’s \( P_k \)| 14.54% | 6.49% | 3.57% | 1.86% |

Table 3

Exp.Suite 1: The Precision, Recall and Beeferman’s \( P_k \) metric values for the datasets Set0, Set1, Set2, Set3, Set4 and Set5, using sentences as a unit of segment, obtained by a validation procedure.

From the aforementioned method of generating texts, it is obvious that, the 200 generated texts for segmentation are longer than those generated during the first suite of experiments. Thus the segmentation of such texts consists a more difficult
problem. We used the same validation procedure as before with the same values for the parameters $r$ and $\gamma$. The obtained validated results are listed in the table below:

| 2nd suite of Experiments |
|--------------------------|
| Precision                | 60.60% |
| Recall                   | 57.00% |
| Beeferman’s $P_k$        | 11.07% |

Table 4

Exp.Suite 2: The Precision, Recall and Beeferman’s $P_k$ metric values for the unique dataset using paragraphs as a unit of segment obtained by a validation procedure.

4. Discussion

Our algorithm was previously tested on Choi’s data collection (Kehagias, A et al. 2003), which contains English texts, achieving significantly better results than the ones previously reported in Choi (2000), Choi et al. (2001) and Utiyama & Isahara (2001). Since the collection used here has not been previously used in the literature for the purpose of text segmentation, we cannot provide a direct comparative assessment. However, the performance obtained is comparable and in most cases better than the corresponding on the Choi’s collection, even though, for several cases the problem dealt by our algorithm is more difficult. The difficulty lies in the fact that, the thematic area dealt by several authors is very similar (see Table 1). One of the reasons for the high segmentation accuracy is the robustness of the POS tagger used. We have observed that, in general, the tagger fails to find the tag and lemma of very technical words. The use of them as they appear in the original text, does not have a negative impact on the segmentation accuracy. The robustness of our algorithm is also indicated by the performance obtained at the second suite of experiments where the segment length is bigger and the deviation from the average length is high. Even in that case our algorithm achieved very high results. This is the result of the combination of the following facts: First, the use of the segment length term in the cost function seems to improve segmentation accuracy significantly. Second, the use of ‘generalized density’ ($r \neq 2$) appears to significantly improve performance. Even though the use of ‘true density’ ($r = 2$) appears more natural, the best segmentation performance (minimum value of $P_k$) is achieved for significantly smaller values of $r$. This performance in most cases is improved when using appropriate values of $\mu, \sigma, \gamma$ and $r$ derived from training data and parameter validation.

Finally, it is worth mentioning that our approach is ‘global’ in two respects. First, sentence similarity is computed globally through the use of the $D$ matrix and dotplot. Second, this global similarity information is also optimized globally by the use of the dynamic programming algorithm. This is in contrast with the local optimization of global information (used by Choi) and global optimization...
of local information (used by Heinonen).

It is worth mentioning that, the computational complexity of our algorithm is comparable to that of the other methods (namely $O(T^2)$ where $T$ is the number of sentences). Finally, our algorithm has the advantage of automatically determining the optimal number of segments.

5. Conclusion

We have presented a dynamic programming algorithm which performs text segmentation by global minimization of a segmentation cost consisting of two terms: within-segment word similarity and prior information about segment length. The performance of our algorithm is quite satisfactory considering that it yields a high segmentation accuracy in a text collection containing Greek texts. In the future we intent to use other measures of sentence similarity. We also plan to apply our algorithm to a wide spectrum of text segmentation tasks. We are interested in the segmentation of non artificial real life texts, texts having a diverse distribution of segment length, long texts, and change-of-topic detection in newsfeeds.

Acknowledgements

The author would like to thank G. Orphanos for kindly letting her use the POS Tagger for the preprocessing of the Greek texts, professor E. Stamatatos for providing the corpus of Greek articles, and professors A. Kehagias and V. Petridis for their undivided guidance and support.
