Oscillations and their applications in partition calculus

Laura Fontanella and Boban Veličković

Equipe de Logique, Université de Paris 7, 2 Place Jussieu, 75251 Paris, France

Abstract. Oscillations are a powerful tool for building examples of colorings witnessing negative partition relations. We survey several results illustrating the general technique and present a number of applications.

1 Introduction

We start by recalling some well known notation. Given three cardinals $\kappa, \lambda, \mu$ and $n < \omega$, the notation

$$\kappa \rightarrow (\lambda)_\mu^n$$

means that for all function $f : [\kappa]^n \rightarrow \mu$, there exists $H \subseteq \kappa$ with $|H| = \lambda$ and such that $f \upharpoonright [H]^n$ is constant. We say that $f$ is a coloring of $[\kappa]^n$ in $\mu$ colors and $H$ is an homogeneous set. Given $\kappa, \lambda, \mu, \sigma$ and $n$ as before, we write

$$\kappa \rightarrow [\lambda]_\mu^n$$

if for every coloring $f : [\kappa]^n \rightarrow \mu$ there exists $H \subseteq \kappa$ of cardinality $\lambda$ such that $f''[H]^n \neq \mu$. We write

$$\kappa \rightarrow [\lambda]_{\mu, \sigma}^n$$

if for every coloring $f : [\kappa]^n \rightarrow \mu$ there exists $H \subseteq \kappa$ of cardinality $\lambda$ such that $|f''[H]^n| \leq \sigma$.

One can extend the above notation to sets with additional structures, such as linear or partial orderings, graphs, trees, topological or vector spaces, etc. For instance, given two topological spaces $X$ and $Y$, then

$$X \rightarrow (\text{top } Y)_\mu^n$$

means that for all $f : [X]^n \rightarrow \mu$ there exists a subset $H$ of $X$ homeomorphic to $Y$ such that $f \upharpoonright [H]^n$ is constant. Similarly, we can define statements such as $X \rightarrow [\text{top } Y]^n_\mu$, $X \rightarrow [\text{top } Y]_\mu^{\omega, \sigma}$, etc.

We denote by $[\mathbb{N}]^{<\omega}$ the set of all finite subsets of $\mathbb{N}$ and by $[\mathbb{N}]^\omega$ the set of all infinite subsets of $\mathbb{N}$. We often identify a set $s$ in $[\mathbb{N}]^{<\omega}$ (or $[\mathbb{N}]^\omega$) with its increasing enumeration. When we do this, we will write $s(i)$ for the $i$-th element of $s$, assuming it exists. In this way, we identify $[\mathbb{N}]^\omega$ with $^{<\omega}$, the set of strictly increasing sequences from $\omega$ to $\omega$, which is a $\mathcal{G}_\delta$ subset of the Baire space $\omega^\omega$, and thus is itself a Polish space. For $s, t \in [\mathbb{N}]^{<\omega}$ we write $s \sqsubseteq t$ to say that $s$ is an initial segment of $t$. In this way, we can view $([\mathbb{N}]^{<\omega}, \sqsubseteq)$ as a tree. For a
given $s \in [\mathbb{N}]^{<\omega}$ we denote by $N_s$ the set of all infinite increasing sequences of integers which extend $s$. In general, if $T$ is a subtree of $[\mathbb{N}]^{<\omega}$ then $T_s$ will denote the set of all sequences of $T$ extending $s$. We will need some basic properties of the Baire space (or rather $[\mathbb{N}]^{\omega}$) and the Cantor space $\{0,1\}^{\omega}$ with the usual product topologies. For these facts and all undefined notions, we refer the reader to [3].

The paper is organized as follows. In §2 we discuss partitions of the rationals as a topological space. The basic tool is oscillations of finite sets of integers. In §3 we consider infinite oscillations of tuples of real numbers and discuss several applications to the study of inner models of set theory. In §4 we discuss finite oscillations of tuples of reals of a slightly different type. Finally, in §5 we present oscillations of pairs of countable ordinals and, in particular, outline Moore’s ZFC construction of an $L$-space. We point out that none of the results of this paper are new and we will give a reference to the original paper for each of the results we mention. Our goal is not to give a comprehensive survey of all applications of oscillations in combinatorial set theory, but rather to present several representative results which illustrate the general method.

These are lecture notes of a tutorial given by the second author at the 2nd Young Set Theory Workshop held at the CRM in Bellaterra, April 14-18 2009. The notes were taken by the first author.

2 Negative Partition Relations on the Rationals

We start with a simple case of oscillations. Given $s, t \in [\mathbb{N}]^{<\omega}$ we define an equivalence relation $\sim$ on $s \triangle t$ by:

$$n \sim m \iff ([n, m] \subseteq (s \setminus t) \lor [n, m] \subseteq (t \setminus s)),$$

for all $n \leq m$ in $s \triangle t$. We now define the function $\text{osc} : ([\mathbb{N}]^{<\omega})^2 \to \mathbb{N}$ by

$$\text{osc}(s, t) = |(s \triangle t)/\sim|,$$

for all $s, t \in [\mathbb{N}]^{<\omega}$. If, for example, $s$ and $t$ are the two sets represented in the following picture, then $\text{osc}(s, t) = 4$.

![Diagram](image)

The following theorem is due to Baumgartner (see [1]).

**Theorem 1 ([1]).** $\mathbb{Q} \not\rightarrow [\text{top } \mathbb{Q}]^2$. 
This means, with our notation, that there exists a coloring \( c : [\mathbb{Q}]^2 \to \omega \) such that \( c''[A]^2 = \omega \), for all \( A \subseteq \mathbb{Q} \) with \( A \approx \mathbb{Q} \).

Consider \([\mathbb{N}]^{<\omega}\) with the topology of pointwise convergence. Let \( X \subseteq [\mathbb{N}]^{<\omega}\) and \( s \in [\mathbb{N}]^{<\omega}\). Then \( s \in X\) iff for every \( n > \sup(s)\) there is \( t \in X\) such that \( t \cap n = s\). Given \( s, t \in [\mathbb{N}]^{<\omega}\) we will write \( s < t\) if \( \max(s) < \min(t)\).

**Remark 1.** It is well known that \( \mathbb{Q} \approx [\mathbb{N}]^{<\omega}\), so we can view osc as a coloring of \([\mathbb{Q}]^2\).

In order to prove Theorem 1, we recall the definition of the Cantor-Bendixson derivative:

\[
\delta(X) = \{ x \in X : \exists t \in X \setminus \{ x \} \},
\]

\[
\delta^0(X) = X,
\]

\[
\delta^{k+1}(X) = \delta(\delta^k(X)).
\]

We need the following lemma.

**Lemma 1.** Suppose \( X \subseteq [\mathbb{N}]^{<\omega}\) and \( k > 0\) is an integer such that \( \delta^k(X) \neq \emptyset\). Then \( \text{osc}''[X]^2 \supseteq \{ 1, 2, \ldots, 2k-1 \} \).

**Proof.** The proof is by induction on \( k\). First assume \( k = 1\), then let \( s \in \delta(X)\). This means that we can find \( t, u \in X\) such that \( s \subseteq t, u \) and \( t \setminus s < u \setminus s\). It follows that \( \text{osc}(t, u) = 1\). Assume that the property holds for all \( l < k\), we show that \( \text{osc}''[X]^2\) takes values \( 2k - 2, 2k - 1\). Fix \( s \in \delta^k(X)\). Recursively pick \( u_i, t_i \in \delta^{k-i}(X)\), for all \( i \leq k\), such that the following hold:

1. \( t_0 = u_0 = s\);
2. \( s \subseteq t_1 \subseteq t_2 \cdots \subseteq t_k\);
3. \( s \subseteq u_1 \subseteq u_2 \cdots \subseteq u_k\);
4. \( t_i \setminus t_{i-1} < u_i \setminus u_{i-1} < t_{i+1} \setminus t_i\), for all \( i \in \{1, 2, \ldots, k\}\).

Then \( \text{osc}(t_{k-1}, u_{k-1}) = 2k - 2\) and \( \text{osc}(t_k, u_{k-1}) = 2k - 1\). \(\square\)

**Proof.** (of Theorem 1). By Remark 1, it is sufficient to check that for all \( A \subseteq [\mathbb{N}]^{<\omega}\) homeomorphic to \( \mathbb{Q}\), \( \text{osc}''[A]^2 = \omega\). Since \( A \approx \mathbb{Q}\), we have \( \delta^k(A) \neq \emptyset\), for all integers \( k\). Hence we can apply Lemma 1 and this completes the proof. \(\square\)

An unpublished result of Galvin states that

\[
\eta \to [\eta]_n^2
\]

when \( \eta \) is the order type of the rational numbers, and \( n \) is any integer. Therefore, the order theoretic version of Theorem 1 does not hold. Also, the coloring we build to prove Baumgartner’s theorem is not continuous. In fact, if we only consider continuous colorings, then we have

\[
\mathbb{Q} \to_{cont} [\text{top } \mathbb{Q}]_2^2.
\]

If we want a continuous coloring, we need to work in \([\mathbb{Q}]^3\). The following result is due to Todorčević (10).
Theorem 2 ([10]). There is a continuous coloring \( c : [\mathbb{Q}]^3 \to \omega \) such that \( c''[A]^3 = \omega \), for all \( A \subseteq \mathbb{Q} \) with \( A \approx \mathbb{Q} \).

Proof. Given \( s, t, u \in [\mathbb{N}]^{<\omega} \), we define
\[
\triangle(s, t) = \min(s \triangle t),
\]
\[
\triangle(s, t, u) = \max\{\triangle(s, t), \triangle(t, u), \triangle(s, u)\}.
\]
The value of \( \triangle(s, t, u) \) is equal to the least \( n \in \mathbb{N} \) such that \( |\{s \cap (n+1), t \cap (n+1), u \cap (n+1)\}| = 3 \). So, in particular, for such an integer \( n \), we have \( |\{s \cap n, t \cap n, u \cap n\}| = 2 \). Let \( \{v, w\} = \{s \cap n, t \cap n, u \cap n\} \), then we define
\[
osc_3(s, t, u) = osc(v, w).
\]
The coloring \( osc_3 \) is obviously continuous. The proof that this coloring works is similar to the one given for Theorem 1. We can prove, analogously, that if \( X \subseteq [\mathbb{N}]^{<\omega} \) and \( \delta_k(X) \neq \emptyset \), for some integer \( k > 0 \), then \( osc_3''[X]^2 \supseteq \{1, 2, ..., 2k - 1\} \).

Let us just see the case \( k = 1 \). Fixing \( s \in \delta(X) \) we can find \( t, u \in X \) such that \( s \sqsubseteq t, u \) and \( t \setminus s < u \setminus s \). Then \( osc_3(s, t, u) = 1 \). Finally one can apply this result to all subsets of \( [\mathbb{N}]^{<\omega} \) that are homeomorphic to \( \mathbb{Q} \), and this completes the proof. \( \square \)

3 Oscillations of Real Numbers - Part 1

We now discuss infinite oscillations and their applications.

Let \( x \subseteq \mathbb{N} \), we define an equivalence relation \( \sim_x \) on \( \mathbb{N} \setminus x \):
\[
n \sim_x m \iff [n, m] \cap x = \emptyset,
\]
for all \( n \leq m \) in \( \mathbb{N} \setminus x \). Thus, the equivalence classes of \( \sim_x \) are the intervals between consecutive elements of \( x \). Given \( x, y, z \subseteq \mathbb{N} \), suppose that \( (I_k)_{k \leq t} \) for \( t \leq \omega \) is the natural enumeration of those equivalence classes of \( x \) which meet both \( y \) and \( z \). We define a function \( o(x, y, z) : t \to \{0, 1\} \) as follows:
\[
o(x, y, z)(k) = 0 \iff \min(I_k \cap y) \leq \min(I_k \cap z).
\]

Notice that \( o \) is a continuous function from
\[
\{(x, y, z) \in ([\mathbb{N}]^{<\omega})^3 : |(\mathbb{N} \setminus x)/\sim_x| = \aleph_0\}
\]
to \( 2^{\leq \omega} \).

Note that \( [\mathbb{N}]^{<\omega} \) ordered by \( \sqsubseteq \) is a tree. A subset \( T \) of \( [\mathbb{N}]^{<\omega} \) is a subtree if it is closed under initial segments.

Definition 1. Let \( T \) be a subtree of \( [\mathbb{N}]^{<\omega} \). We say that \( t \in T \) is \( \infty \)-splitting if for all \( k \) there exists \( u \in T \) such that \( t \sqsubseteq u \) and \( u(|t|) > k \).
Definition 2. A subtree $T$ of $[N]^\omega$ is superperfect if for all $s \in T$ there exists $t \in T$ such that $s \sqsubseteq t$ and $t$ is $\infty$-splitting in $T$.

Definition 3. $X \subseteq [N]^\omega$ is superperfect if there is a superperfect tree $T \subseteq [N]^\omega$ such that $X = [T] = \{ A \in [N]^\omega : A \cap k \in T, \text{ for all } k \}$.

The following theorem is due to Veličković and Woodin (11).

Theorem 3 (11). Let $X, Y, Z \subseteq [N]^\omega$ be superperfect sets. Then $o''[X \times Y \times Z] \supseteq 2^\omega$.

Proof. Let $T_1, T_2, T_3 \subseteq [N]^\omega$ be superperfect trees such that $X = [T_1], Y = [T_2]$ and $Z = [T_3]$. Given an $\alpha \in 2^\omega$, we build sequences $(s_k)_k, (t_k)_k, (u_k)_k$, of nodes of $T_1, T_2$ and $T_3$, respectively, such that the following properties hold:

1. $s_0, t_0, u_0$ are the least $\infty$-splitting node of $T_1, T_2$ and $T_3$, respectively;
2. $s_0 \sqsubseteq s_1 \sqsubseteq s_2 \sqsubseteq \cdots \sqsubseteq s_k \sqsubseteq \cdots$;
3. $t_0 \sqsubseteq t_1 \sqsubseteq t_2 \sqsubseteq \cdots \sqsubseteq t_k \sqsubseteq \cdots$;
4. $u_0 \sqsubseteq u_1 \sqsubseteq u_2 \sqsubseteq \cdots \sqsubseteq u_k \sqsubseteq \cdots$;
5. $t_k \setminus t_{k-1}, u_k \setminus u_{k-1} < s_k \setminus s_{k-1}$;
6. $t_k \setminus t_{k-1} < u_k \setminus u_{k-1},$ if $\alpha(i) = 0$ and $u_k \setminus u_{k-1} < t_k \setminus t_{k-1},$ if $\alpha(i) = 1$.

If $x = \bigcup_{k<\omega} s_k, y = \bigcup_{k<\omega} t_k$ and $z = \bigcup_{k<\omega} u_k$, then $o(x, y, z) = \alpha$ and this completes the proof. □

Corollary 1 (11). If $X \subseteq [N]^\omega$ is a superperfect set, then $o''[X]^3 \supseteq 2^\omega$. □

We now apply the previous theorem to prove some results about reals of inner models of set theory.

Theorem 4 (11). Let $V, W$ be models of set theory such that $W \subseteq V$. If there is a superperfect set $X$ in $V$ such that $X \subseteq W$ then $R^W = R^V$.

Proof. This is trivial by applying Corollary 1. □

Question 1. Can we replace superperfect by perfect in the previous theorem?

Surprisingly, the answer depends on whether CH holds in the model $W$, as it is asserted in the following theorem due to Groszek and Slaman (see [4]).

Theorem 5 (4). Suppose that $W$ and $V$ are two models of set theory such that $W \subseteq V$. Assume that there is a perfect set $P$ in $V$ such that $P \subseteq W$. If CH holds in $W$, then $R^W = R^V$.

In order to prove this theorem, let us introduce the following notion.
Definition 4. Given two models of set theory $W$ and $V$ such that $W \subseteq V$ we say that $(W, V)$ satisfies the countable covering property for the reals if, for all $X$ in $V$ such that $X \subseteq \mathbb{R}^W$ and $X$ is countable in $V$, there is an $Y$ in $W$ such that $X \subseteq Y$ and $Y$ is countable in $W$.

We prove first the following theorem.

Theorem 6. Given two models of set theory $W$ and $V$ such that $W \subseteq V$, suppose that there is a perfect set $P$ in $V$ such that $P \subseteq W$. If $(W, V)$ satisfies the countable covering property for the reals, then $\mathbb{R}^W = \mathbb{R}^V$.

Proof. Work in $V$ and fix a perfect subset $P$ of $(2^\omega)^W$. Let $X$ be a countable dense subset of $P$. By the countable covering property for the reals we can cover $X$ by some set $D \in W$ such that $D$ is countable in $W$, is a dense subset of $2^\omega$ and $D \cap P$ is dense in $P$. In $W$, fix an enumeration $\{d_n; n < \omega\}$ of $D$. For $x, y \in 2^\omega$ with $x \neq y$ let

$$\Delta(x, y) = \min\{n : x(n) \neq y(n)\}.$$

Given $x \in 2^\omega \setminus D$ first define a sequence $\langle k_x(n); n < \omega \rangle$ by induction as follows

$$k_x(n) = \min\{k : \Delta(x, d_k) > \Delta(x, d_{k_{x(i)}}), \text{ for all } i < n\}.$$

Note that $k_x(0) = 0$. Since $D$ is dense in $P$ and $x \in P \setminus D$ then $k_x(n)$ is defined, for all $n$. Now define $f : P \setminus D \rightarrow [\omega]^\omega$ by setting

$$f(x)(n) = \Delta(x, d_{k_x(n)}).$$

Clearly, $f$ is continuous and $f(x)$ is a strictly increasing function, for all $x \in 2^\omega \setminus D$. Since $D \in W$ then $f$ is coded in $W$. We can now prove that $f''[P \setminus D]$ is superperfect. Let $T = \{f(x) \mid n : x \in P \setminus D \wedge n \in \omega\}$. First note that $f''[P \setminus D]$ is closed, i.e. it is equal to $[T]$. To see this, note that if $b \in [T]$, then for every $i$ there is $x_i \in P \setminus D$ such that $b \supseteq f(x_i) \supseteq i$. Since $P$ is compact, it follows that the sequence $(x_i)_i$ converges to some $x \in P$. Note then $k_x(n) = k_{x_m}(n)$, for all $m > n$, in particular, $k_x(n)$ is defined, for all $n$. It follows that $x \notin D$. Since $f(x) = b$ it follows that $b \in f''[P \setminus D]$, as desired.

Now, we show that every node of $T$ is $\omega$-splitting. Let $s \in T$ and suppose $n = |s|$. Then there is some $x \in P \setminus D$ such that $s \subseteq f(x)$. Therefore, $s(i) = \Delta(x, d_{k_x(i)})$, for all $i < n$. Let $l = k_x(n)$. Since $P$ is perfect we can find, for every $j \geq \Delta(x, d_l)$, some $x_j \in P \setminus D$ such that $\Delta(x_j, d_l) \geq j$. It follows that $f(x_j)(n) \subseteq n$ and $f(x_j)(n) = j$. This shows that $s$ is $\omega$-splitting.

Since $P \subseteq W$ and $f$ is coded in $W$ we have $f''[P \setminus D] \subseteq W$, that is $W$ contains a superperfect set. By Corollary 4 we have $\mathbb{R}^W = \mathbb{R}^V$ and this completes the proof.

Proof. (of Theorem 5). By the previous theorem, it is enough to prove that $(W, V)$ satisfies the countable covering property for the reals. By assumption, $W$ satisfies CH, so we can fix in $W$ a well-ordering on $(\mathbb{R})^W$ of height $(\omega_1)^W$. Since every perfect set is uncountable and $P \subseteq W$, then $\omega_1^W = \omega_1^V$. Therefore, any
$X \subseteq (\mathbb{R})^W$ which is countable in $V$, is contained in a proper initial segment $Y$ of the well-ordering. Then $Y \in W$ and $Y$ is countable in $W$. This completes the proof.

In particular we can state the following corollary.

**Corollary 2 ([H]).** If there is a perfect set of constructible reals, then $\mathbb{R} \subseteq L$. □

Is the countable covering condition necessary to obtain this result? Theorem 7 below (see [11]) gives a partial answer to this question.

**Theorem 7 ([11]).** There is a pair $(W, V)$ of generic extensions of $L$ with $W \subseteq V$, such that $\aleph_1^W = \aleph_1^V$ and $V$ contains a perfect set of $W$-reals, but $\mathbb{R}^W \neq \mathbb{R}^V$.

On the other hand, in [11] we have also the following theorem.

**Theorem 8 ([11]).** Suppose that $M$ is an inner model of set theory and $\mathbb{R}^M$ is analytic, then either $\aleph_1^M$ is countable, or all reals are in $M$.

In order to prove Theorem 8 let us introduce a generalization of the notion of a superperfect set.

**Definition 5.** Suppose $\lambda$ is a limit ordinal and $T$ is a subtree of $[\lambda]^{<\omega}$. We say that $t \in T$ is $\lambda$-splitting if for all $\xi < \lambda$ there exists $u \in T$ such that $t \subseteq u$ and $u(|t|) > \xi$.

**Definition 6.** Suppose $\lambda$ is a limit ordinal and let $T$ be a subtree of $[\lambda]^{<\omega}$. We say $T$ is $\lambda$-superperfect if for all $s \in T$ there exists $t \in T$ such that $s \subseteq t$ and $t$ is $\lambda$-splitting.

**Definition 7.** A set $P \subseteq [\lambda]^{\omega}$ is $\lambda$-superperfect if there is a $\lambda$-superperfect tree $T \subseteq [\lambda]^{<\omega}$ such that $P = \{x \in [\lambda]^{\omega} : \forall n < \omega(x \upharpoonright n \in T)\}$. Here $x \upharpoonright n$ denotes the set of the first $n$ elements of $x$ in the natural order.

The definition of $o : ([\mathbb{N}]^{\omega})^3 \to \{0,1\}^{\omega}$ can be trivially generalized to a coloring $o_\lambda : ([\lambda]^{\omega})^3 \to \{0,1\}^{\omega}$.

As for $o$ one can easily check that for all $\lambda$-superperfect $P$, we have $o_\lambda[^3P] \supseteq \{0,1\}^{\omega}$ (the proof is the same as for Theorem 3). Moreover, we have $o_\lambda(x, y, z) \in L[x, y, z]$, for all $x, y, z \in [\lambda]^{\omega}$. To complete the proof of Theorem 8 it suffices to prove the following lemma.

**Lemma 2.** Suppose that $A$ is an analytic set such that $\sup\{\omega_1^{CK,x} : x \in A\} = \omega_1$. Then every real is hyperarithmetic in a quadruple of elements of $A$. 7
Proof. Let $T \subset (\omega \times \omega)^{<\omega}$ be a tree such that $A = p[T]$. Note that the statement $\sup\{\omega^1_{CK,x} : x \in p[T]\} = \omega_1$ is $\Pi^1_2(T)$ and thus absolute.

For an ordinal $\alpha$ let $\text{Coll}(\aleph_0, \alpha)$ be the usual collapse of $\alpha$ to $\aleph_0$ using finite conditions. Let $\mathcal{P}$ denote $\text{Coll}(\aleph_0, \aleph_1)$. If $G$ is $V$-generic over $\mathcal{P}$, by Shoenfield’s absoluteness theorem, in $V[G]$ there is $x \in p[T]$ such that $\omega^1_{CK,x} > \omega^1_V$. In $V$ fix a name $\hat{x}$ for $x$ and a name $\sigma$ for a cofinal $\omega$-sequence in $\omega^1_V$ such that the maximal condition in $\mathcal{P}$ forces that $\hat{x} \in p[T]$ and $\sigma \in L[\hat{x}]$.

**Claim 1** For every $p \in \mathcal{P}$ there is $k < \omega$ such that for every $\alpha < \omega_1$ there is $q \leq p$ such that $q \Vdash \sigma(k) > \alpha$.

**Proof.** Assume otherwise and fix $p$ for which the claim is false. Then for every $k$ there is $\alpha_k < \omega_1$ such that $p \Vdash \sigma(k) < \alpha_k$. Let $\alpha = \sup\{\alpha_k : k < \omega\}$. Then $p \Vdash \text{ran}(\sigma) \subseteq \alpha$, contradicting the fact that $\sigma$ is forced to be cofinal in $\omega^1_V$. □

Let $Q$ denote $\text{Coll}(\aleph_0, \aleph_2)$ as defined in $V$. Suppose $H$ is $V$-generic over $Q$. Work for a moment in $V[H]$. If $G$ is a $V$-generic filter over $\mathcal{P}$ let $\sigma_G$ denote the interpretation of $\sigma$ in $V[G]$. Let $B$ be the set of all $\sigma_G$ where $G$ ranges over all $V$-generic filters over $\mathcal{P}$.

**Claim 2** $B$ contains an $\omega^1_V$-superperfect set in $(\omega^1_V)^{<\omega}$.

**Proof.** Let $\{D_n : n < \omega\}$ be an enumeration of all dense subsets of $\mathcal{P}$ which belong to the ground model. For each $t \in (\omega^1_V)^{<\omega}$ we define a condition $p_t$ in the regular open algebra of $\mathcal{P}$ as computed in $V$ and $s_t \in (\omega^1_V)^{<\omega}$ inductively on the length of $t$ such that

1. $p_t \in D_{lh(t)}$
2. $p_t \Vdash s_t \subseteq \sigma$
3. If $t \subseteq r$ then $p_r \leq p_t$ and $s_t \subseteq s_r$
4. if $t$ and $r$ are incomparable then $s_t$ and $s_r$ are incomparable
5. for every $t$ the set $\{\alpha < \omega_1 : \text{ there is } q \leq p \text{ such that } q \Vdash s_t \upharpoonright \alpha \subseteq \sigma\}$ is unbounded in $\omega^1_V$.

Suppose $p_t$ and $s_t$ have been defined. Using 5, choose in $V$ a 1-1 order preserving function $f_t : \omega^1_V \to \omega^1_V$ and for every $\alpha q_{t,\alpha} \leq p_t$ such that $q_{t,\alpha} \Vdash s_t \upharpoonright f_t(\alpha) \subseteq \sigma$. By extending $q_{t,\alpha}$ if necessary, we may assume that it belongs to $D_{lh(t)+1}$. Now, by applying Claim 1, we can find a condition $p \leq q_{t,\alpha}$ and $k > lh(s_t) + 1$ such that for some $s \in (\omega^1_V)^k$ $p \Vdash s \subseteq \sigma$ and for every $\gamma < \omega^1_V$ there is $q \leq p$ such that $q \Vdash \sigma(k) > \gamma$. Let then $s_t \upharpoonright \alpha = s$ and $p_t \upharpoonright \alpha = p$. This completes the inductive construction.

Now if $b \in (\omega^1_V)^{<\omega}$ then $\{p_b|n : n < \omega\}$ generates a filter $G_b$ which is $V$-generic over $\mathcal{P}$. The interpretation of $\sigma$ under $G_b$ is $s_b = \bigcup_{n<\omega} s_b|n$. Since the set $R = \{s_b : b \in (\omega^1_V)^{<\omega}\}$ is $\omega^1_V$-superperfect, this proves Claim 2. □

Now, using the remark following Definition 7, for any real $r \in \{0, 1\}^{<\omega}$ we can find $b_1, b_2, b_3 \in (\omega^1_V)^{<\omega}$ such that $r \in L[s_{b_1}, s_{b_2}, s_{b_3}]$. Let $x_1$ be the interpretation.
of $\dot{x}$ under $G_b$. Then it follows that $x_i \in p[T]$ and $s_{b_i} \in L[x_i]$, for $i = 1, 2, 3$. Thus $r \in L[x_1, x_2, x_3]$. Pick a countable ordinal $\delta$ such that $r \in L[\omega^\omega]$. Using the fact that in $V[H]$ $\sup\{\omega_1^{CK} : x \in p[T]\} = \omega_1$, we can find $y \in p[T]$ such that $\omega_1^{CK, y} > \delta$. Then we have that $r$ is $\Delta^1_1(x_1, x_2, x_3)$. Note that the statement that there are $x_1, x_2, x_3, y \in p[T]$ such that $r \in \Delta^1_1(x_1, x_2, x_3)$ is $\Sigma^2$ $\omega$. For any real $r \in V$, by Shoenfield absoluteness again, it must be true in $V$. This proves Lemma 2.

We complete this section by stating some related results.

**Theorem 9 ([11]).** There is a pair of generic extensions of $L$, $W \subseteq V$ such that $R_W$ is an uncountable $F_\delta$ set in $V$, and $R_W \neq R_V$.

**Theorem 10 ([3]).** Suppose that $W \subseteq V$ are two models of set theory, $\kappa > \omega_1^V$ and there exists $C \subseteq [\kappa]^{\omega}$ which is a club in $V$ such that $C \subseteq W$. Then $R_W = R_V$.

**Theorem 11 ([2]).** Suppose that $W \subseteq V$ are two models of set theory such that $V, W \models PFA$ and $\aleph_2^W = \aleph_2^V$. Then $R_W = R_V$, in fact $P(\omega_1)^W = P(\omega_1)^V$.

## 4 Oscillations of Real Numbers - part 2

The results of this section are taken from [9]. We look increasing sequences of integers and slightly change the definition of oscillation. Given $s, t \in (\omega)^{\omega}$ we define

$$\text{osc}(s, t) = |\{n < \omega : s(n) \leq t(n) \land s(n+1) > t(n+1)\}|.$$

In the next picture, $s$ and $t$ are two functions in $(\omega)^{\omega}$ with $\text{osc}(s, t) = 2$.

![Oscillation Example](image-url)

We now define two orders $\leq_m$ and $\leq_*$ on $(\omega)^{\omega}$:

$$f \leq_m g \iff \forall n \geq m(f(n) \leq g(n));$$

$$f \leq_* g \iff \exists m(f \leq_m g).$$

Given $X \subseteq (\omega)^{\omega}$ and $s \in (\omega)^{<\omega}$ we let $X_s = \{f \in X : s \subseteq f\}$ and $T_X = \{s \in (\omega)^{<\omega} : X_s \text{ is unbounded under } \leq_*\}$. 

9
Lemma 3. Suppose that $X \subseteq (\omega)\omega$ is unbounded under $\leq_*$ and $X = \bigcup_{n < \omega} A_n$. Then there exists $n$ such that $A_n$ is unbounded.

Proof. Suppose that every $A_n$ is bounded and, for all $n$, let $g_n$ be such that $f \leq_* g_n$, for all $f \in A_n$. If we define $g(n) = \sup\{g_k(n) : k \leq n\}$, then $X$ is bounded by $g$ with respect to $\leq_*$. This leads to a contradiction. □

Lemma 4. Suppose that $X \subseteq (\omega)\omega$ is unbounded under $\leq_*$. Then $T_X$ is superperfect.

Proof. Suppose, by way of contradiction, that there is a node $s \in T_X$ with no $\infty$-splitting extensions in $T_X$. We define a function $g_s : \omega \rightarrow \omega$ as follows:

$$g_s(n) = \sup\{t(n) : t \in (T_X)_s \land n \in \text{dom}(t)\},$$

where $(T_X)_s = \{f \in T_X : s \sqsubseteq f\}$. First note that $g_s(n) < \omega$, for all $n < \omega$. Let $Q = \{t \in (\omega)^{<\omega} : X_t$ is bounded under $\leq_*\}$. By Lemma 3 $\bigcup_{X_t : t \in Q}$ is bounded under $\leq_*$ by some function $g$. Now let $h = \max(g, g_s)$. It follows that $X_s$ is $\leq_*$-bounded by $h$, a contradiction. □

We first consider oscillations of elements of $(\omega)^{<\omega}$. Our first goal is to prove that if $T$ is a superperfect subtree of $(\omega)^{<\omega}$ then osc$\omega[T]^2 = \omega$. In fact, we prove a slightly stronger lemma.

Lemma 5. Let $S$ and $T$ be two superperfect subtrees of $(\omega)^{<\omega}$ and let $s$ and $t$ be $\infty$-splitting nodes of $S$ and $T$ respectively. Then for all $n$ there are $\infty$-splitting nodes $s'$ in $S$ and $t'$ in $T$ such that $s \sqsubseteq s'$, $t \sqsubseteq t'$ and

$$\text{osc}(s', t') = \text{osc}(s, t) + n.$$

Proof. We may assume without loss of generality that $|s| < |t|$ and $s(|s| - 1) \leq t(|s| - 1).$ We can recursively pick some $\infty$-splitting extensions $s_i \in S$ and $t_i \in T$, for $i \leq n$ such that:

- $s_0 = s$ and $t_0 = t$;
- $s_0 \sqsubseteq s_1 \sqsubseteq \cdots \sqsubseteq s_n$;
- $t_0 \sqsubseteq t_1 \sqsubseteq \cdots \sqsubseteq t_n$;
- $\text{osc}(s_i, t_i) = \text{osc}(s, t) + i$, for all $i$;
- $|s_i| < |t_i|$ and $s_i(|s_i| - 1) \leq t_i(|s_i| - 1)$.

Given $s_i$ and $t_i$, since $S$ is superperfect and $s_i$ is $\infty$-splitting in $S$, we can find some $\infty$-splitting extension $u$ of $s_i$ in $S$ such that $u(|s_i|) > t_i(|t_i| - 1)$ and such that $|u| > |t_i| + 1$. In the same way, we can take an $\infty$-splitting extension $v$ of $t_i$ in $T$ such that $v(|t_i|) > u(|u| - 1)$ and $|v| > |u| + 1$. Since $u$ and $v$ are strictly increasing, we have $\text{osc}(u, v) = \text{osc}(s_i, t_i) + 1$, so we can define $s_{i+1} = u$ and $t_{i+1} = v$.

Finally, $\text{osc}(s_n, t_n) = \text{osc}(s, t) + n$ and this completes the proof. □
Corollary 3. If $T$ is a superperfect subtree of $(\omega)^<\omega$ then $\text{osc}''[T]^2 = \omega$. □

We now turn to oscillations of elements of $(\omega)\omega$. We will need the following definition.

Definition 8. A subset $X$ of $(\omega)\omega$ is $\sigma$-directed under $\leq_*$ if, and only if, for all countable $D \subseteq X$ there is $f \in X$ such that $d \leq_* f$, for all $d \in D$.

Lemma 6. Suppose $X \subseteq (\omega)\omega$ and $\sigma$-directed and unbounded under $\leq_*$ and $Y \subseteq (\omega)\omega$ is such that for every $a \in X$ there is $b \in Y$ such that $a \leq_* b$. There is an integer $n_0$ such that for all $k < \omega$ there is $f \in X$ and $g \in Y$ such that $\text{osc}(f, g) = n_0 + k$.

Proof. Fix a countable dense subset $D$ of $X$. Since $X$ is $\sigma$-directed, there is a function $a \in X$ such that $d \leq_* a$, for all $d \in D$. The set $Y' = \{g \in Y : a \leq_* g\}$ is unbounded under $\leq_*$. We define $Y_m = \{g \in Y' : a \leq_m g\}$, for all $m < \omega$. By Lemma 3 and the fact that $Y' = \bigcup\{Y_m : m < \omega\}$, there exists $m_0 < \omega$ such that $Y_{m_0}$ is also $\leq_*$-unbounded. Let $s_0 \in T_X$ and $t_0 \in T_{Y_{m_0}}$ be the two least $\omega$-splitting nodes of $T_X$ and $T_{Y_{m_0}}$ respectively. Let $n_0 = \text{osc}(s_0, t_0)$. Now, fix $k < \omega$. By Lemma 5 there are two $\omega$-splitting $s \in T_X$ and $t \in T_{Y_{m_0}}$ such that $\text{osc}(s, t) = n_0 + k$. We may assume without loss of generality that $|t| \leq |s|$ and $t(|t| - 1) > s(|t| - 1)$. Since $D$ is dense, there is $f \in D$ such that $s \subseteq f \leq_* a$. Fix $m \geq m_0$ such that $f \leq m a$. Since $t$ is $\omega$-splitting in $T_{Y_{m_0}}$, we can pick $i > f(m)$ and $g \in Y_{m_0}$, such that $t^\uparrow i \subseteq g$. We know that for all $k \geq m_0$, $a(k) \leq g(k)$, so for all $k \geq m$, $f(k) \leq g(k)$. Moreover, $f$ and $g$ are increasing and $t^\uparrow i \subseteq g$, so for all $k$ between $|t|$ and $m$ we have $g(k) > f(k)$. It follows that $\text{osc}(f, g) = \text{osc}(s, t) = n_0 + k$ and this completes the proof. □

The following theorem is due to S. Todorčević (see [9]).

Theorem 12 ([9]). Suppose $X \subseteq (\omega)\omega$ is unbounded under $\leq_*$ and $\sigma$-directed, then $\text{osc}''[X]^2 = \omega$.

Proof. The proof is the same as for Lemma 6 by assuming $Y = X$. Thus $s_0 = t_0$ and, consequently, $n_0 = 0$ in the previous proof. Hence, for all $k < \omega$ there are $f, g \in X$ such that $\text{osc}(f, g) = k$. This completes the proof. □

We recall that $b$ is the least cardinal of an $\leq_*$-unbounded subset of $(\omega)\omega$. Fix an unbounded $\mathcal{F} \subseteq (\omega)\omega$ of cardinality $b$. We may assume that $\mathcal{F}$ is well ordered under $\leq_*$ and $(\mathcal{F}, \leq_*)$ has order type $b$.

Remark 2. Every unbounded subset of $\mathcal{F}$ is $\sigma$-directed and cofinal in $\mathcal{F}$ under $\leq_*$.

Corollary 4. Let $X, Y \subseteq \mathcal{F}$ be unbounded under $\leq_*$. There exists $n_0 < \omega$ such that for all $k < \omega$ there exist $f \in X$ and $g \in Y$ such that $\text{osc}(f, g) = n_0 + k$.

Proof. Trivial by Remark 2 and Lemma 6. □

In [9], Todorčević proved a more general result:
Theorem 13 ([9]). Suppose $\mathcal{F}$ is $\leq_{*}$-unbounded and well ordered by $\leq_{*}$ in order type $b$. Suppose $\mathfrak{A} \subseteq [\mathcal{F}]^n$, $|\mathfrak{A}| = b$ and $\mathfrak{A}$ consists of pairwise disjoint $n$-tuples. Then there exists $h : n \times n \to \omega$ such that for all $k < \omega$ there exist $A, B \in \mathfrak{A}$ such that $A \neq B$ and $\text{osc}(A(i), B(j)) = h(i, j) + k$, for all $i, j < n$. Here $A(i)$ denotes the $i$-th element of $A$ in increasing order, and similarly $B(j)$ denotes the $j$-th element of $B$.

**Proof.** For any $A, B \in [\mathcal{F}]^n$, we will write $A <_{m} B$ if, and only if, $a <_{m} b$ for all $a \in A$ and $b \in B$. Similarly, with $A \leq_{*} B$ we mean that $a \leq_{*} b$, for all $a \in A$ and $b \in B$. Finally, if $A \in \mathfrak{A}$ and $m < \omega$, we denote by $A \upharpoonright m$ the sequence $\langle A(i) \mid m \rangle_{i<\omega}$.

We may assume that $\mathfrak{A}$ is **everywhere unbounded**, that is for all $m < \omega$ and $A \in \mathfrak{A}$, the set $\{ B \in \mathfrak{A} : B \upharpoonright m = A \upharpoonright m \}$ is also unbounded in $((\omega^{\omega})^n)$ under $\leq_{*}$. Take a countable dense $\mathcal{D} \subseteq \mathfrak{A}$. There is $A \in \mathfrak{A}$ such that $D \leq_{*} A$, for all $D \in \mathcal{D}$. For all $m < \omega$, let $A_{m} = \{ B \in \mathfrak{A} : A <_{m} B \}$. As before, there is $m_{0} < \omega$ such that $A_{m_{0}}$ is everywhere unbounded.

Given any $t \in (\omega^{\omega})^{n}$, we denote by $t_{i}$ the $i$-th element of $t$ in increasing order. If $B \in (\omega^{\omega})^{n}$, then $t \sqsubseteq B$ means $t_{i} \sqsubseteq B(i)$, for all $i < n$. Now, we define

$$T_{A_{m_{0}}} = \{ t \in (\omega^{\omega})^{n} : \forall i < n(|t_{i}| < |t_{i+1}|) \land \exists B \in A_{m_{0}}(t \sqsubseteq B) \}. $$

For any sequence $s \in T_{A_{m_{0}}}$, we say that $s$ is **$\infty$-splitting** if for all $l < \omega$, there is $t \in T_{A_{m_{0}}}$ such that $s \sqsubseteq t$ and $t_{i}(|s_{i}|) > l$, for all $i < n$.

**Claim 3** $T_{A_{m_{0}}}$ is superperfect, that is for all $s \in T_{A_{m_{0}}}$, there is an $\infty$-splitting sequence $t \in T_{A_{m_{0}}}$ such that $s \sqsubseteq t$.

**Proof.** Given $s \in T_{A_{m_{0}}}$, define $t_{0}$ as the least $\infty$-splitting extension of $s_{0}$ in $T_{Z(0)}$, where $Z(0) := \{ B(0) : B \in A_{m_{0}} \}$. Assume that $t \upharpoonright i$ is defined, the set $Z(i) := \{ B(i) : B \in A_{m} \land B \upharpoonright i = t \upharpoonright i \}$ is unbounded (because $A_{m_{0}}$ is everywhere unbounded). Put $t_{i}$ any $\infty$-splitting extension of $s_{i}$ in $T_{Z(i)}$, such that $|t_{i}| > |t_{i-1}|$. The sequence $t$, so defined, is $\infty$-splitting in $T_{A_{m_{0}}}$. This completes the proof of the claim. \[ \square \]

Now, let $r \in T_{A_{m_{0}}}$ be the least $\infty$-splitting sequence, we define for all $i, j < n$,

$$h(i, j) = \text{osc}(r_{i}, r_{j}).$$

**Claim 4** For all $k < \omega$, there are two $\infty$-splitting sequences $s, t \in T_{A_{m_{0}}}$ such that $r \subseteq s, t$ and $\text{osc}(s_{i}, t_{j}) = \text{osc}(r_{i}, r_{j}) + k$, for all $i, j < n$.

**Proof.** We prove this by induction on $k < \omega$. The case $k = 0$ is trivial. Let $s, t \in T_{A_{m_{0}}}$ be $\infty$-splitting, such that $r \subseteq s, t$ and $\text{osc}(s_{i}, t_{j}) = \text{osc}(r_{i}, r_{j}) + k$, for all $i, j$. Assume without loss of generality that $|s_{i}| < |t_{j}|$ and $s_{j}(\lfloor |s_{i}| \rfloor - 1) \leq t_{j}(\lfloor |s_{i}| \rfloor - 1)$, for all $i, j$. Since $s$ is $\infty$-splitting, there is an $\infty$-splitting sequence $u \in T_{A_{m_{0}}}$ such that $s \subseteq u$ and $u_{i}(\lfloor |s_{i}| \rfloor) > t_{j}(\lfloor |t_{j}| \rfloor - 1)$, for all $i, j$. We ask, also, for $u_{i} > \lfloor |t_{j}| \rfloor + 1$, for all $i, j$. Similarly, we can find an $\infty$-splitting sequence $v \in T_{A_{m_{0}}}$ such that $t \subseteq v$ and $v_{i}(\lfloor |v_{i}| \rfloor) > u_{j}(\lfloor |u_{j}| \rfloor - 1)$, for all $i, j$. It follows that $\text{osc}(u_{i}, v_{j}) = \text{osc}(s_{i}, t_{j}) + 1$ for all $i, j$. This completes the proof of the claim. \[ \square \]
Fix \( s \) and \( t \) as in Claim 14. Assume without loss of generality that \( |s_i| \leq |t_j| \) and \( s_i(|s_i| - 1) > t_j(|s_j| - 1) \), for all \( i, j \). Consider, now, the families \( X = \{ B \in \mathcal{A} : t \sqsubseteq B \} \) and \( \mathcal{D}' = \mathcal{D} \cap X \). We have that \( X \) is everywhere unbounded and \( \mathcal{D}' \) is dense in \( X \). Take any \( D \in \mathcal{D}' \), then \( t \sqsubseteq D <, m \) for some \( m > m_0 \). Since \( s \) is \( \infty \)-splitting there is \( l \geq D(n-1)(m) \) and \( B \in A_{m_0} \) such that \( s^{-1}l := \langle s_i^{-1}l \rangle_{i<n} \sqsubseteq B \). By construction, \( osc(D(i), B(j)) = osc(s_i, t_j) = h(i, j) + k \), for all \( i, j < n \). This completes the proof.

Sometimes we need to improve \( osc \) to get an even better coloring. First we want to get rid of the function \( h \) of Theorem 13. We fix a bijection \( \omega \rightarrow \omega \times \omega \). We define a new partial function \( f, g \) as follows: given \( s, t \in A_{m_0} \) and \( l \), want to get rid of the function \( h \) of Theorem 13. We fix a bijection \( \omega \rightarrow \omega \times \omega \). We define a new partial function \( f, g \) as follows: given \( s, t \in A_{m_0} \) and \( l \), consider the function \( \pi \) on pairs of elements of \((\omega)^{<\omega}\) or \((\omega)^{\omega}\) as follows. Suppose \( osc(f, g) = 2^{i_0} + 2^{i_1} + \cdots + 2^{i_k} \) for \( i_0 > i_1 > \cdots > i_k \), be the binary expansion of \( osc(f, g) \). We define \( o(f, g) = \pi_0 \circ e(i_0) \) where \( \pi_0 \) is the projection on the first component.

**Lemma 7.** Suppose \( \mathcal{F} \) and \( \mathcal{A} \subseteq [\mathcal{F}]^n \) are as in Theorem 13. Then for all \( k < \omega \) there exists \( A, B \in \mathcal{A} \) such that \( A \neq B \) and \( o(A(i), B(j)) = k \), for all \( i, j < n \).

**Proof.** Given \( k \), consider the function \( h : n \times n \rightarrow \omega \) of Theorem 13. For all \( i, j < n \), let \( l_{i,j} \) be the largest integer such that \( 2^{l_{i,j}} \leq h(i, j) \) and let \( l = \max \{ l_{i,j} : i, j < n \} \). The set \( \{ m : \exists p(e(m) = (k, p)) \} \) is infinite so we can find \( m > l \) such that \( \pi_0 \circ e(m) = k \). By definition of \( h \) there exist two different \( A, B \in \mathcal{A} \) such that \( osc(A(i), B(j)) = h(i, j) + 2^m \), for all \( i, j < n \). It follows that \( o(A(i), B(j)) = \pi_0 \circ e(m) = k \), for all \( i, j < n \). This completes the proof.

Finally we want to be able to choose the color of \( \{ A(i), B(j) \} \) independently for all \( i, j \). First we need the following lemma.

**Lemma 8.** Given \( \mathcal{A} \subseteq [\mathcal{F}]^n \) an unbounded family of pairwise disjoint sets. There are \( k < \omega \) and \( \mathcal{A}^* \subseteq \mathcal{A} \) unbounded such that, for all \( i < n \), there exists \( a_i \in (\omega)^k \) such that \( A(i) \upharpoonright k = a_i \), for all \( A \in \mathcal{A}^* \) and \( a_i \neq a_j \), for all \( i \neq j < n \).

**Proof.** We prove it by induction on \( n < \omega \). It is trivial for \( n = 1 \). Assume that the statement is true for \( n \), we prove it for \( n + 1 \). Given \( \mathcal{A} \subseteq [\mathcal{F}]^{n+1} \), let be \( k < \omega \), \( \mathcal{A}' \subseteq \mathcal{A} \upharpoonright n \), and \( \{ a_i \}_{i<n} \) as in the conclusion of the lemma for \( \mathcal{A} \upharpoonright n \). The set \( \mathcal{B} = \{ A \in \mathcal{A} : A \upharpoonright n \in \mathcal{A}' \} \) is unbounded, hence \( X = \{ A(n) : A \in \mathcal{B} \} \) is also unbounded. By Lemma 13 we have that \( T_X \) is superperfect, so let \( b \) be the least \( \infty \)-splitting node of \( T_X \). We can assume without loss of generality that \( |b| < k \). Take any \( a_n \sqsubseteq b \) in \( T_X \) such that \( |a_n| = k \) and \( a_n(k-1) > \max \{ a_i(k-1) : i < n \} \). Then \( a_n \neq a_i \), for all \( i < n \). Recall that \( T_X = \{ s \in (\omega)^{<\omega} : \{ f \in X : s \sqsubseteq f \} \) is unbounded \}, hence \( \mathcal{A}^* = \{ B \in \mathcal{B} : a_n \sqsubseteq B(n) \} \) is unbounded. This completes the proof.

Consider all finite functions \( t : D \times E \rightarrow \omega \) where \( D, E \subseteq (\omega)^k \) and \( k \) is an integer. Let \( \{ (t_n, D_n, E_n, k_n) \}_{n<\omega} \) be any enumeration of such functions. We define \( c : [\mathcal{F}]^2 \rightarrow \omega \) as follows: given \( f, g \in \mathcal{F} \) and letting \( n = o(f, g) \), we define

\[
c(f, g) = \begin{cases} 
t_n(f \upharpoonright k_n, g \upharpoonright k_n) & \text{if } f \upharpoonright k_n \in D_n \text{ and } g \upharpoonright k_n \in E_n \\
0 & \text{otherwise}
\end{cases}
\]
Theorem 14 ([9]). Given an unbounded family $\mathcal{A} \subseteq [\mathcal{F}]^n$ of pairwise disjoint sets, and an arbitrary $u : n \times n \rightarrow \omega$, there are two different $A, B \in \mathcal{A}$ such that $c(A(i), B(j)) = u(i, j)$, for all $i, j < n$.

Proof. Take $k < \omega$, $\mathcal{A}^k$ and let $D = \{a_i : i < n\}$. Consider the function $t : D \times D \rightarrow \omega$ defined by $t(a_i, a_j) = u(i, j)$, for all $i, j < n$. Assume that $(t_m, D_m, E_m, k_m)$ is the corresponding sequence in the previous enumeration. By Lemma 7 there exist different $A, B \in \mathcal{A}^k$ such that $o(A(i), B(j)) = m$, for all $i, j < n$. It follows that $u(i, j) = t(a_i, a_j) = t_m(A(i) \restriction k_m, B(j) \restriction k_m) = c(A(i), B(j))$. This completes the proof. \hfill \Box

Corollary 5. There is a $\mathfrak{b} - c.c.$ partial order whose square is not $\mathfrak{b} - c.c.$ \hfill \Box

The following question is still open.

Question 2. Can we do the same for some other cardinal invariant such as $\mathfrak{t}$ or $\mathfrak{p}$?

5 Partitions of countable ordinals

Oscillations provide the main tool for constructing partitions of pairs of countable ordinals with very strong properties. The goal of this section is to present the construction of an $L$-space due to Moore [7] which uses oscillations in an ingenious way. In order to motivate this construction we start with a simple example.

For each limit $\alpha < \omega_1$, fix $c_\alpha \subseteq \alpha$ cofinal of order type $\omega$. As before, we will view $c_\alpha$ both as a set and as an $\omega$-sequence which enumerates it in increasing order. Thus, we will write $c_\alpha(n)$ for the $n$-th element of $c_\alpha$. The sequence $\langle c_\alpha : \alpha < \omega_1, \lim(\alpha) \rangle$ is called a $c$-sequence.

We can generalize the definition of osc as follows: for $f, g \in (\omega_1)^{\leq \omega}$,

$$\text{osc}(f, g) = |\{n < \omega : f(n) \leq g(n) \land f(n+1) > g(n+1)\}|.$$  

Given a subset $S$ of $\omega_1$ consisting of limit ordinals, let

$$U_S = \{s \in [\omega_1]^{<\omega} : \alpha \in S : s \subseteq c_\alpha\}$$

be stationary.

Lemma 9. Assume $S \subseteq \omega_1$ is stationary. Then $U_S$ is an $\omega_1$-superperfect tree.

Proof. Given $s \in U_S$ let $(U_S)_s = \{t \in U_S : s \subseteq t\}$ and let $\alpha_{s,n} = \sup\{t(n) : t \in (U_S)_s\}$. Then there is $n$ such that $\alpha_{s,n} = \omega_1$. To see this, assume otherwise and let $\alpha = \sup\{\alpha_{s,n} : n < \omega\}$. Then $\alpha < \omega_1$. For each $\delta \in S \setminus (\alpha + 1)$ such that $s \subseteq c_\delta$ let $n_\delta$ be the least integer such that $c_\delta(n_\delta) > \alpha$. By the Pressing Down Lemma, there is $t \in [\omega_1]^{<\omega}$ such that $s \subseteq t$ and the set $\{\delta \in S : c_\delta \restriction (n_\delta + 1) = t\}$ is stationary. It follows that $s \subseteq t \in U_S$ and $\max(t) > \alpha$, a contradiction. \hfill \Box

Lemma 10. Given two stationary sets $S, T \subseteq \omega_1$, there is $n_0 < \omega$ such that for all $k < \omega$ there exist $\alpha \in S$ and $\beta \in T$ such that $\text{osc}(c_\alpha, c_\beta) = n_0 + k$. 

14
Proof. By Lemma 9 both $U_S$ and $U_T$ are $\omega_1$-superperfect. Let $s$ and $t$ be the least $\omega_1$-splitting nodes of $U_S$ and $U_T$ respectively. We may assume that $|s| \leq |t|$ and $s(|s| - 1) \leq t(|s| - 1)$. Let $n_0 = \text{osc}(s, t) + 1$. Now, as in the proof of Lemma 5, given an integer $k$ we can find $\omega_1$-splitting nodes $s'$ and $t'$ of $U_S$ and $U_T$ respectively, such that $s' \subseteq s$, $t' \subseteq t$ and $\text{osc}(s', t') = n_0 + k - 1$. Moreover, we can arrange that $|s'| \leq |t'|$ and $s'(|s'| - 1) \leq t'(|s'| - 1)$. Now, let $\alpha \in S$ such that $s' \triangleleft \alpha$. It follows that $\text{osc}(\alpha, \beta) = \text{osc}(s', t') + 1 = n_0 + k$, as desired. 

We can then improve osc as before to get some better coloring. We know that our coloring cannot be as strong as in the case of $h$, since MA$_{\aleph_1}$ implies that the countable chain condition is productive, so we have to give up some of the properties of our coloring.

We now present a construction of Moore \cite{Moore} of a coloring of pairs of countable ordinals witnessing $\omega_1 \not\rightarrow [\omega_1; \omega_1]^2_2$ and use it to construct an $L$-space. As before we fix a sequence $\langle C_\alpha : \alpha < \omega_1 \rangle$ such that

- if $\alpha = \xi + 1$, then $C_\alpha = \{\xi\}$;
- if $\alpha$ is limit, then $C_\alpha \subseteq \alpha$ is cofinal and of order type $\omega$.

Given $\alpha < \beta$ we define the walk from $\beta$ to $\alpha$. We first define a sequence $\beta_0 > \beta_1 \cdots > \beta_l = \alpha$ as follows:

- $\beta_0 = \beta$;
- $\beta_{i+1} = \min(C_{\beta_i} \setminus \alpha)$.

Then we define $\xi_0 \leq \xi_1 \cdots \leq \xi_{l-1}$ by setting

$$\xi_k = \max \left\{ \bigcup_{j=0}^{k} (C_{\beta_j} \cap \alpha) \right\},$$

for all $k \leq l - 1$. We call $\text{Tr}(\alpha, \beta) = \{\beta_0, \ldots, \beta_l\}$ the upper trace and $L(\alpha, \beta) = \{\xi_0, \ldots, \xi_{l-1}\}$ the lower trace of the walk from $\beta$ to $\alpha$. 

15
Lemma 11. Suppose that $\alpha \leq \beta \leq \gamma$ and $\max(L(\beta, \gamma)) < \min(L(\alpha, \beta))$, then $L(\alpha, \gamma) = L(\alpha, \beta) \cup L(\beta, \gamma)$.

Proof. Since $\max(L(\beta, \gamma)) < \min(L(\alpha, \beta))$, we have $C_\xi \cap \alpha = C_\xi \cap \beta$ whenever $\xi$ is in $\text{Tr}(\beta, \gamma)$ and $\xi \neq \beta$. It follows that $\beta \in \text{Tr}(\alpha, \gamma)$ and $\text{Tr}(\alpha, \gamma) = \text{Tr}(\alpha, \beta) \cup \text{Tr}(\beta, \gamma)$. Assume $\text{Tr}(\alpha, \gamma) = \{\gamma_0, ..., \gamma_l\}$ and $L(\alpha, \gamma) = \{\xi_0, ..., \xi_{l-1}\}$, there is $l_0 \leq l$ such that $\gamma_{l_0} = \beta$. Therefore, $\{\xi_k\}_{k \leq l_0 - 1} = L(\beta, \gamma)$. On the other hand $\max(C_{\gamma_{l_0}} \cap \alpha) > \xi_{l_0 - 1}$ because $\xi_{l_0 - 1} \in L(\beta, \gamma)$ and $\max C_{\gamma_{l_0}} \in L(\alpha, \beta)$, hence if $k \geq l_0$, then

$$\xi_k = \max_{j=0}^{k} (C_{\gamma_j} \cap \alpha) = \max_{j=l_0}^{k} (C_{\gamma_j} \cap \alpha),$$

and so $L(\alpha, \beta) = \{\xi_k\}_{k=l_0}^{l_0 - 1}$.

Lemma 12. If $\alpha < \beta$, then $L(\alpha, \beta)$ is a non empty finite set and, for every limit ordinal $\beta$, $\lim_{\alpha \to \beta} \min(L(\alpha, \beta)) = \beta$.

Proof. The first statement is trivial, let us prove that $\lim_{\alpha \to \beta} \min(L(\alpha, \beta)) = \beta$, for every limit ordinal $\beta$. Given $\alpha < \beta$, one can take $\alpha' \in C_\beta \setminus (\alpha + 1)$. Then $\alpha < \alpha' = \max(C_\beta \cap (\alpha' + 1)) = \min L(\alpha' + 1, \beta) \leq \lim_{\alpha \to \beta} \min(L(\alpha, \beta))$. It follows that $\beta \leq \lim_{\alpha \to \beta} \min(L(\alpha, \beta)) \leq \beta$, and this completes the proof.

Fix a sequence $\langle e_\alpha : \alpha < \omega_1 \rangle$ satisfying the following conditions:

1. $e_\alpha : \alpha \to \omega$ is finite-to-one;
2. $\alpha < \beta$ implies $e_\beta \upharpoonright \alpha = e_\alpha$, i.e. $\{\xi < \alpha : e_\beta(\xi) \neq e_\alpha(\xi)\}$ is finite.
Given $\alpha < \beta < \omega_1$ let $\Delta(\alpha, \beta)$ be the least $\xi < \alpha$ such that $e_\alpha(\xi) \neq e_\beta(\xi)$, if it exists, and $\alpha$ otherwise. We define $\text{osc}(\alpha, \beta)$ as follows

$$\text{osc}(\alpha, \beta) = |\{i \leq l - 1 : e_\alpha(\xi_i) \leq e_\beta(\xi_i) \wedge e_\alpha(\xi_{i+1}) > e_\beta(\xi_{i+1})\}|$$

where $L(\alpha, \beta) = \{\xi_0 < \cdots < \xi_{l-1}\}$.

It will be convenient also to use the notation $\text{Osc}(e_\alpha, e_\beta, L(\alpha, \beta))$ for the set 

$$\{\xi_i \in L(\alpha, \beta) : e_\alpha(\xi_i) \leq e_\beta(\xi_i) \wedge e_\alpha(\xi_{i+1}) > e_\beta(\xi_{i+1})\}.$$ 

Our aim is to prove the following theorem due to J. Moore (see [7]).

**Theorem 15 ([7]).** Let $A, B \subseteq \omega_1$ be uncountable, then for all $n < \omega$ there exist $\alpha \in A, \beta_0, \beta_1, \ldots, \beta_{n-1} \in B$ and $k_0$ such that $\alpha < \beta_0, \ldots, \beta_{n-1}$ and $\text{osc}(\alpha, \beta_m) = k_0 + m$, for all $m < n$.

This means that we can get arbitrary long intervals of oscillations with a fixed lower point $\alpha \in A$. We can generalize this to get even more:

**Theorem 16 ([7]).** Given $\mathfrak{A} \subseteq [\omega_1]^k$ and $\mathfrak{B} \subseteq [\omega_1]^l$ uncountable and pairwise disjoint, and given $n < \omega$, we can find $A \in \mathfrak{A}$ and $B_0, \ldots, B_{n-1} \in \mathfrak{B}$ such that $\max A < \min B_i$, for all $i < n$, and $\text{osc}(A(i), B_m(j)) = \text{osc}(A(i), B_0(j)) + m$ for all $i < k, j < l$ and $m < n$.

In order to prove Theorem 15 we demonstrate the following lemma.

**Lemma 13.** Let $A, B \subseteq \omega_1$ be uncountable. There exists a club $C \subseteq \omega_1$ such that if $\delta \in C, \alpha \in A \setminus \delta$, $\beta \in B \setminus \delta$, and $R \in \{=, >\}$, then there are $\alpha' \in A \setminus \delta$ and $\beta' \in B \setminus \delta$ satisfying the following properties:

1. $\max L(\alpha, \beta) < \Delta(\alpha, \alpha'), \Delta(\beta, \beta')$;
2. $L(\delta, \beta) \subseteq L(\delta, \beta')$;
3. for all $\xi \in L^+ = L(\delta, \beta') \setminus L(\delta, \beta)$, we have $e_{\alpha'}(\xi) \mathrel{R} e_{\beta'}(\xi)$.

**Proof.** Fix a sufficiently large regular cardinal $\theta$. We will show that if $M \prec H_\theta$ is a countable elementary substructure containing all the relevant objects, then $\delta = M \cap \omega_1$ satisfies the conclusion of the lemma. Since the set of such $\delta$ contains a club in $\omega_1$ this will be sufficient. Thus, fix $M$ and $\delta$ as above and let $\alpha$ and $\beta$ be as in the hypothesis of the lemma. We first suppose that $R$ is $=$. Since $\delta$ is a limit ordinal, we can take $\gamma_0 < \delta$ such that:

1. $\max(L(\delta, \beta)) < \gamma_0$;
2. for all $\xi \in (\gamma_0, \delta)$, $e_\alpha(\xi) = e_\beta(\xi)$.

By Lemma 12 we can fix also $\gamma < \delta$ such that $\gamma_0 < \min L(\xi, \delta)$, for all $\xi \in (\gamma_0, \gamma)$. Let $D$ be the set of all $\delta' < \omega_1$ such that for some $\alpha' \in A \setminus \delta'$ and $\beta' \in B \setminus \delta'$ the following properties are satisfied:

1. $\alpha' \mathrel{\downarrow} \gamma_0 = e_\alpha \mathrel{\downarrow} \gamma_0, e_{\beta'} \mathrel{\downarrow} \gamma_0 = e_\beta \mathrel{\downarrow} \gamma_0$;
2. $L(\delta', \beta') = L(\delta, \beta)$;
3. for all $\xi \in (\gamma_0, \delta')$, $\gamma_0 < \min L(\xi, \delta')$;
4. $\gamma < \delta$.

(d) for all \( \xi \in (\gamma_0, \delta') \), \( e_{\alpha'}(\xi) = e_{\beta'}(\xi) \).

Observe that for all \( \xi \geq \gamma_0, e_{\xi} \upharpoonright \gamma_0 = e_{\gamma_0} \). This means that \( D \) is definable in \( M \), hence \( D \in M \). Moreover \( D \not\subseteq M \) (since \( \delta \in D \)) hence \( D \) is uncountable. Choose \( \delta' > \delta \) in \( D \) with \( \alpha' \in A \setminus \delta' \) and \( \beta' \in B \setminus \delta' \) witnessing \( \delta' \in D \). By condition (a) of the definition of \( D \),

\[
\gamma_0 \leq \Delta(\alpha, \alpha'), \Delta(\beta, \beta').
\]

Put \( L^+ = L(\delta, \delta') \), then \( \max L(\delta, \beta) = \max L(\delta', \beta') < \min L^+ \), hence

\[
L(\delta, \beta') = L(\delta', \beta') \cup L^+ = L(\delta, \beta) \cup L^+.
\]

Given \( \xi \in L^+ \), by condition (c), we have \( \gamma_0 < \min L^+ \leq \xi \). It follows that \( \xi \in (\gamma_0, \delta') \), so (d) implies \( e_{\alpha'}(\xi) = e_{\beta'}(\xi) \).

Now assume that \( R \) is \( > \). Let \( E \) be the set of all limits \( \nu < \omega_1 \) such that for all \( \alpha_0 \in A \setminus \nu, \nu_0 < \nu, \varepsilon < \omega_1, n < \omega \) and finite \( L^+ \subseteq \omega_1 \setminus \nu \), there exists \( \alpha_1 \in A \setminus \varepsilon \) with \( \nu_0 \leq \Delta(\alpha_0, \alpha_1) \) and \( e_{\alpha_1}(\xi) > n \), for all \( \xi \in L^+ \). Since \( E \) is definable from parameters in \( M \) it follows \( E \in M \), as well.

**Claim 5** The ordinal \( \delta \) is in \( E \). In particular \( E \) is uncountable.

**Proof.** Let \( \alpha_0, \nu_0, \varepsilon, n, L^+ \) be given as in the definition of \( E \) for \( \nu = \delta \). Since \( e_{\alpha_0} \) is finite-to-one, we can assume w.l.o.g. that \( \nu_0 > \sup\{ \xi < \delta : e_{\alpha_0}(\xi) \leq n \} \). By the elementarity of \( M \), there exists \( \delta' > \varepsilon, \delta \), max \( L^+ \) and \( \alpha_1 \in A \setminus \delta' \) such that the following conditions hold:

- \( e_{\alpha_0} \upharpoonright \nu_0 = e_{\alpha_1} \upharpoonright \nu_0 \);
- for all \( \xi \in (\nu_0, \delta') \), we have \( e_{\alpha_1}(\xi) > n \).

Since \( L^+ \subseteq \delta' \setminus \delta \), this completes the proof of the claim. \( \square \)

Now apply the elementarity of \( M \) and the fact that \( E \) is uncountable to find \( \gamma_0 \in E \) such that \( L(\delta, \beta) < \gamma_0 < \delta \). By Lemma 12 we can find a \( \gamma < \delta \) such that if \( \xi \in (\gamma, \delta) \), then \( \gamma_0 < L(\xi, \delta) \). Again by the elementarity of \( M \) select limit \( \delta' > \delta \) and \( \beta' \in B \setminus \delta' \) such that the following conditions hold:

- \( e_{\beta'} \upharpoonright \gamma_0 = e_{\beta} \upharpoonright \gamma_0 \);
- \( L(\delta', \beta') = L(\delta, \beta) \);
- \( \gamma < \xi < \delta' \) implies \( \gamma_0 < L(\xi, \delta') \).

Put \( L^+ = L(\delta, \delta') \), then \( L^+ \subseteq \omega_1 \setminus \gamma_0 \). Since \( \gamma_0 \in E \) we can apply the definition of \( E \) with \( \nu_0 = \max L(\delta, \beta) + 1, n = \max\{ e_{\beta'}(\xi) : \xi \in L^+ \} \) to find \( \delta' \in A \setminus \delta \) such that for all \( \xi \in L^+ \), max \( L(\delta, \beta) < \Delta(\alpha, \alpha') \) and \( e_{\alpha'}(\xi) > e_{\beta'}(\xi) \). This completes the proof of Lemma 13. \( \square \)

We can finally prove Theorem 15.
Proof. (of Theorem 15). Let $A, B \subseteq \omega_1$ be two uncountable sets and let $M \preceq H_{\aleph_1}$ be a countable substructure containing everything relevant with $\delta = M \cap \omega_1$. Since $M$ contains $A$ and $B$, the club $C$ provided by Lemma 13 is in $M$. Use Lemma 13 to select $\alpha_0, \alpha_1, \ldots, \alpha_n, \ldots$ in $A \setminus \delta, \beta_0, \beta_1, \ldots, \beta_n, \ldots$ in $B \setminus \delta$ and $\xi_0, \xi_1, \ldots, \xi_n, \ldots$ in $\delta$ such that for all $n < \omega$ the following conditions are satisfied:

1. $L(\delta, \beta_n) \sqsubseteq L(\delta, \beta_{n+1})$;
2. $\xi_n \in L(\delta, \beta_{n+1}) \setminus L(\delta, \beta_n)$;
3. $\text{Osc}(e_{\alpha_{n+1}}, e_{\beta_{n+1}}, L(\delta, \beta_{n+1})) = \text{Osc}(e_{\alpha_n}, e_{\beta_n}, L(\delta, \beta_n)) \cup \{\xi_n\};$
4. if $m > n$, then $\xi_n < \triangle(\alpha_m, \alpha_{m+1}), \triangle(\beta_m, \beta_{m+1});$
5. $e_{\alpha_n}(\max L(\delta, \beta_n)) = e_{\beta_n}(\max L(\delta, \beta_n))$.

Suppose $\alpha_n$ and $\beta_n$ have been defined. We obtain $\alpha_{n+1}$ and $\beta_{n+1}$ by applying Lemma 13 twice: first with $R$ being $=$, second with $R$ being $>$. If $\alpha'$ and $\beta'$ are the two ordinals obtained by applying the lemma the first time, then $\xi_n = \min(L(\delta, \beta_{n+1}) \setminus L(\delta, \beta'))$.

Now let $n$ be given, pick $\gamma_0 < \delta$ such that

$$\gamma_0 > \max L(\delta, \beta_n), \max \{\xi < \delta : \exists m, m' \leq n(e_{\beta_m}(\xi) \neq e_{\beta_m'}(\xi))\}.$$ 

Using the elementarity of $M$ and Lemma 12 select $\alpha \in A \cap \delta$ such that

$$\max L(\delta, \beta_n) < \triangle(\alpha, \alpha_n)$$
and $\gamma_0 < \min L(\alpha, \delta)$.

Now let $m < n$ be fixed. It follows from Lemma 11 that

$$L(\alpha, \beta_m) = L(\alpha, \delta) \cup L(\delta, \beta_m).$$

Finally $e_{\beta_m} \rest L(\alpha, \delta)$ does not depend on $m$ since

$$\min L(\alpha, \delta) > \gamma_0 > \max \{\xi < \delta : \exists m, m' \leq n(e_{\beta_m}(\xi) \neq e_{\beta_m'}(\xi))\}.$$ 

Therefore

$$\text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \delta)) = \text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \delta)).$$

By 5., $\text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \beta_m)) = \text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \delta)) \cup \text{Osc}(e_{\alpha}, e_{\beta_m}, L(\delta, \beta_m))$ so by 3., $\text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \beta_m)) = \text{Osc}(e_{\alpha}, e_{\beta_m}, L(\alpha, \beta_0)) \cup \{\xi_n' : m' < m\}$, hence $\text{osc}(\alpha, \beta_m) = \text{osc}(\alpha, \beta_0) + m$ and this completes the proof.

By using the previous results we can, finally, prove the existence of an $L$-space, that is, a regular Hausdorff space which is hereditarily Lindelöf but not hereditarily separable. We will work in $T = \{z \in \mathbb{C} : |z| = 1\}$. We fix a sequence $\langle z_\alpha : \alpha < \omega_1 \rangle$ of rationally independent elements of $\mathbb{T}$. It is easy to find such a sequence since given any countable rationally independent subset $I$ of $T$, there are only countable many $z$ for which $I \cup \{z\}$ is rationally dependent. Consider, now, the function defined as follows:

$$o(\alpha, \beta) = z_\alpha^{\text{osc}(\alpha, \beta) + 1},$$

for all $\alpha < \beta < \omega_1$.

We will use the Kronecker’s Theorem (see 9 or 8) which is the following statement:
Theorem 17. Suppose that \( \langle z_i \rangle_{i<k} \) is a sequence of elements of \( \mathbb{T} \) which are rationally independent. For every \( \epsilon > 0 \), there is \( n_\epsilon \in \mathbb{N} \) such that if \( u, v \in \mathbb{T}^k \), there is \( m < n_\epsilon \) such that
\[
|u_i z_i^m - v_i| < \epsilon,
\]
for all \( i < k \).

We can, now, define the \( L \)-space. For every \( \beta < \omega_1 \), we define a function \( w_\beta : \omega_1 \to \mathbb{T} \) as follows:
\[
w_\beta(\xi) = \begin{cases} 
o(\xi, \beta) & \text{if } \xi < \beta \\
1 & \text{otherwise.}
\end{cases}
\]

Let \( \mathcal{L} = \{ w_\beta : \beta < \omega_1 \} \) viewed as a subspace of \( \mathbb{T}^{\omega_1} \).

Remark 3. \( \mathcal{L} \) is not separable.

For all \( X \subseteq \omega_1 \), let \( \mathcal{L}_X = \{ w_\beta \mid X; \beta \in X \} \) viewed as a subspace of \( \mathbb{T}^X \). We will simply write \( w_\beta \) for \( w_\beta \mid X \) when referring to elements of \( \mathcal{L}_X \). Our aim is to prove that \( \mathcal{L}_X \) is an \( L \)-space, for all \( X \) uncountable.

Lemma 14. Let \( \mathcal{A} \subseteq [\omega_1]^k \) and \( \mathcal{B} \subseteq [\omega_1]^l \) be uncountable families of pairwise disjoint sets. For every sequence \( \langle U_i \rangle_{i<k} \) of open neighborhoods in \( \mathbb{T} \) and every \( \phi : k \to l \), there are \( a \in \mathcal{A} \) and \( b \in \mathcal{B} \) such that \( \max(a) < \min(b) \) and for all \( i < k \),
\[
o(a(i), b(\phi(i))) \in U_i.
\]

Proof. We may assume without loss of generality that every \( U_i \) is an \( \epsilon \)-ball about a point \( v_i \), for some fixed \( \epsilon > 0 \). We can assume also that the integer \( n_\epsilon \) of the Kronecker’s Theorem for the sequence \( \langle z_{a(i)} \rangle_{i<k} \) is uniform for \( a \in \mathcal{A} \). Apply Theorem 16 to find \( a \in \mathcal{A} \) and \( (b_m)_{m<n_\epsilon} \) a sequence of elements of \( \mathcal{B} \) such that
\[
a < b_m
\]
\[
\text{osc}(a(i), b_m(j)) = \text{osc}(a(i), b_0(j)) + m,
\]
for all \( i < k, j < l \) and \( m < n_\epsilon \). For each \( i < k \), put \( u_i = o(a(i), b_0(\phi(i))) \). There is an \( m < n_\epsilon \), such that
\[
|u_i z_{a(i)}^m - v_i| < \epsilon,
\]
for all \( i < k \) or, equivalently, \( o(a(i), b_m(\phi(i))) \) \( \in U_i \). This completes the proof.

\( \square \)

Lemma 15. If \( X, Y \subseteq \omega_1 \) have countable intersection, then there is no continuous injection from any uncountable subspace of \( \mathcal{L}_X \) into \( \mathcal{L}_Y \).

Proof. Suppose, by way of contradiction, that such an injection \( g \) does exist. Then there are an uncountable set \( X_0 \subseteq X \) and an injection \( f : X_0 \to Y \) such that \( g(w_\beta) = w_{f(\beta)} \). We may assume without loss of generality that \( X_0 \) is disjoint from \( Y \). For each \( \xi \in \omega_1 \), let \( \beta_\xi \in X_0 \) and \( \zeta_\xi \in Y \) be such that \( f(\beta_\xi) > \zeta_\xi \).
and if \( \xi < \xi' \), then \( \beta_\xi < \zeta_\xi' \). Let \( \Xi \subseteq \omega_1 \) be uncountable such that for every \( \xi \in \Xi \) there is an open neighborhood \( V \) in \( T \), such that \( g(w_{\beta_\xi})(\zeta_\xi) \notin V \). Let \( W_\xi = \{ w \in L_X : w(\zeta_\xi) \notin V \} \), for all \( \xi < \omega_1 \). Since \( g \) is continuous at \( w_{\beta_\xi} \), there is a basic open neighborhood \( U_\xi \) of \( w_{\beta_\xi} \) such that \( U_\xi \subseteq g^{-1} W_\xi \).

By applying the \( \Delta \)-system lemma and the second countability of \( T \), we can find an uncountable \( \Xi' \subseteq \Xi \), a sequence of open neighborhoods \( \langle U_i \rangle_{i<k} \) in \( T \), and \( a_\xi \in [X]^k \) such that for all \( \xi \in \Xi' \), the following conditions hold:

- \( \{ a_\xi \}_{\xi \in \Xi'} \) is a \( \Delta \)-system with root \( a \);
- \( w_{\beta_\xi} \in \{ w \in L_X : \forall i < k (w(a_\xi(i)) \in U_i) \} \subseteq U_\xi ; \)
- the inequality \( \beta_\xi < f(\beta_\xi) \) does not depend on \( \xi \);
- \( |\zeta_\xi \cap a_\xi| \) does not depend on \( \xi \).

Let \( \mathcal{A} = \{ a_\xi \cup \{ \xi \} \} \) and \( \mathcal{B} = \{ \beta_\xi, f(\beta_\xi) \} \). By applying Lemma 14 we can find \( \xi < \xi' \) in \( \Xi' \) such that for all \( i < k \),

\[
\begin{align*}
    a_\xi \cup \{ \zeta_\xi \} &< \min(\beta_\xi', f(\beta_\xi')), \\
    w_{\beta_\xi'}(a_\xi(i)) &\in U_i, \\
    g(w_{\beta_\xi'})(\zeta_\xi) &\in V.
\end{align*}
\]

We have that \( w_{\beta_\xi'} \notin U_\xi \) and \( g(w_{\beta_\xi'}) \notin W_\xi \). Contradiction.

\[ \square \]

**Theorem 18 (\cite{7}).** For every \( X, L_X \) is hereditarily Lindelöf.

**Proof.** If not, then \( L_X \) would contain an uncountable discrete subspace. Moreover it would be possible to find disjoint \( Y, Z \subseteq X \) such that \( L_Y \) and \( L_Z \) contain uncountable discrete subspaces. It is well known that any function from a discrete space to another discrete space is continuous and this contradicts Lemma 15.

\[ \square \]

**Corollary 6 (\cite{7}).** There exists an \( L \)-space, i.e. a hereditary Lindelöf non separable \( T_3 \) topological space.

\[ \square \]
