Representability of the motivic Brouwer degree

GLEN MATTHEW WILSON

We study which quadratic forms are representable as the local degree of a map \( f : \mathbb{A}^n \rightarrow \mathbb{A}^n \) with an isolated zero at 0, following the work of Kass and Wickelgren who established the connection to the quadratic form of Eisenbud, Khimshiashvili, and Levine. Our main observation is that over some base fields \( k \), not all quadratic forms are representable as a local degree. Empirically the local degree of a map \( f : \mathbb{A}^n \rightarrow \mathbb{A}^n \) has many hyperbolic summands, and we prove that in fact this is the case for local degrees of low rank. We establish a complete classification of the quadratic forms of rank at most 7 that are representable as the local degree of a map over all base fields of characteristic different from 2. The number of hyperbolic summands was also studied by Eisenbud and Levine, where they establish general bounds on the number of hyperbolic forms that must appear in a quadratic form that is representable as a local degree. Our proof method is elementary and constructive in the case of rank 5 local degrees, while the work of Eisenbud and Levine is more general. We provide further families of examples that verify that the bounds of Eisenbud and Levine are tight in several cases.

1 Introduction

The degree of a map in differential topology is a homotopy invariant that completely classifies the homotopy classes of maps between spheres of the same dimension. The work of Morel [7, Corollary 1.24] establishes an analog of this calculation in the setting of motivic homotopy theory, where algebraic varieties like \( \mathbb{A}^n \setminus \{0\} \) and \( \mathbb{P}^n \) can be viewed as spheres. Interestingly, the motivic version of the degree of a map between spheres takes values in the Grothendieck–Witt ring of quadratic forms over the base field \( k \), rather than merely the ring of integers. In differential topology, the degree of a map \( f : S^n \rightarrow S^n \) can be calculated as a sum of local degrees and one must wonder if an analogous result could also be true in motivic homotopy theory as well.

If one assumes the existence of a global degree map \( \deg : [S^n, S^n] \rightarrow \mathbb{Z} \), it is not hard to give an abstract definition of a local degree in topology. By working with coordinate
charts, one can reduce the problem to defining the local degree of a map $f : \mathbb{R}^n \to \mathbb{R}^n$ with an isolated zero at $x \in \mathbb{R}^n$. From such a map, we can find some $\epsilon > 0$ and construct $\frac{f-f(x)}{\|f-f(x)\|} : S^{n-1}(x; \epsilon) \to S^{n-1}$. We then define the local degree of $f$ at $x$ to be the global degree of $\frac{f-f(x)}{\|f-f(x)\|}$.

A modified construction works in motivic homotopy theory, which was studied by Lannes and Morel (see [12]) and Kass and Wickelgren [4]. Let $k$ be a field; write $MW(k)$ for the semiring of isometry classes of quadratic forms over the field $k$ and $GW(k)$ for the group completion of $MW(k)$, i.e., the Grothendieck–Witt group of $k$. For any map $f : \mathbb{A}^n \to \mathbb{A}^n$ with an isolated zero at 0, Kass and Wickelgren [4, Definition 11] construct a map in the motivic homotopy category $f_0 : \mathbb{P}^n/\mathbb{P}^{n-1} \to \mathbb{P}^n/\mathbb{P}^{n-1}$. The map $f_0$ encodes the local behavior of $f$ at 0 and we can then apply Morel’s $\mathbb{A}^1$-Brouwer degree $\deg^A : [\mathbb{P}^n/\mathbb{P}^{n-1}, \mathbb{P}^n/\mathbb{P}^{n-1}] \to GW(k)$ to $f_0$ to obtain the class of a quadratic form in $GW(k)$ that acts as the local degree of $f$ at 0 in motivic homotopy theory. We write $\deg^A_0(f) = \deg^A(f_0)$ for this motivic local degree. The main result of Kass and Wickelgren in [4] is that the local degree $\deg^A_0(f)$ is equal to the class of the Eisenbud–Khimshiashvili–Levine form of $f$ at 0 (henceforth EKL form of $f$ at 0) in $GW(k)$.

With this result, one can turn algebraic results about EKL forms into statements about Morel’s degree homomorphism and motivic homotopy theory. In this paper, we study the structure of EKL forms of a map $f : \mathbb{A}^n \to \mathbb{A}^n$ with isolated zero at 0 and give several applications to motivic homotopy theory and the study of real singularities.

In topology it is simple to come up with explicit maps $f : \mathbb{R}^n \to \mathbb{R}^n$ when $n \geq 2$ with an isolated zero at 0 that have a prescribed local degree $\deg_0(f) = n$. In this paper, we show that a similar statement in motivic homotopy theory is false over a general field $k$. Precisely, for an arbitrary element $q \in MW(k)$, the equation $\deg^A_0(f) = q$ does not always admit a solution $f : \mathbb{A}^n \to \mathbb{A}^n$. Of course, the solvability of these equations depends on the base field. For instance, if $-1$ is not a square in the field $k$, then we show that the quadratic form $q(x, y) = x^2 + y^2$, is never representable as the local degree of a map $f : \mathbb{A}^n \to \mathbb{A}^n$. In fact, we show something much stronger: every quadratic form with rank at least 2 that is representable as a local degree contains the hyperbolic form $\mathbb{H}(x, y) = x^2 - y^2$ as a direct summand.

This theorem is proven by proving the corresponding result for EKL forms at 0. That is, every EKL form at 0 that has rank at least 2 contains $\mathbb{H}$ as a direct summand, see Theorem 2. This result, coupled with some explicit examples, gives a complete description of which quadratic forms of rank at most 4 are representable as an EKL form at 0. It takes us considerably more effort to produce a complete classification of EKL forms of rank 5, which is Theorem 18: Any quadratic form of rank 5 that is representable as a local degree at 0 is of the form $2\mathbb{H} + \langle a \rangle$ for some unit $a$. This result
then can be translated into motivic homotopy theory using Morel’s degree isomorphism to say something about which maps of spheres are representable as local degree maps. See Theorem 33 for a precise statement. The main tool we use in the classification of the rank 5 EKL forms is a dimension reduction argument, stated in Theorem 15. This generalizes an observation McKean had in the 2-variable case [6, Lemma 5.7]. The effect of our dimension reduction result allows us to reduce the study of rank 5 EKL forms to maps $f : \mathbb{A}^2 \to \mathbb{A}^2$. This can then be checked directly by brute force using some properties of Gröbner bases.

After discovering the results above about the representability of quadratic forms as local degrees in motivic homotopy theory, we found that an analogous question was originally studied by Eisenbud and Levine, using a technical result of Teissier in their paper [2]. In this paper, Eisenbud and Levine tried to understand how the local degree of a smooth map germ $f : \mathbb{R}^n \to \mathbb{R}^n$ could be determined from the structure of the local ring $Q_0(f)$. They show that the topological local degree of $f$ at 0 is the signature of the EKL form of $f$ at 0 and then investigate what kind of restrictions there are on the signature of an EKL form when the dimension of $Q_0(f)$ is known. Without explicitly stating it, they are simply obtaining bounds on the number of hyperbolic summands that the EKL form must have for a fixed rank—exactly the question we set out to study, albeit in a slightly different context. Eisenbud and Levine ultimately establish a more general result on the minimal number of hyperbolic forms that must appear in an EKL form of fixed rank using a fundamental inequality of Teissier [2, Appendix, p. 38]. They show that an EKL form of rank $n$ arising from a map $f : \mathbb{A}^m \to \mathbb{A}^m$ must have at least $\frac{n^2 - n}{2}$ hyperbolic summands [2, Theorem 3.9(i)]. They also include the weaker statement without a dependence on the dimension $m$ that an EKL form of rank $n$ must contain at least $\frac{n}{2}$ hyperbolic summands [2, Theorem 3.9(ii)]. Their general inequality gives an alternative proof that a rank 5 EKL form must be of the form $2\mathbb{H} + \langle a \rangle$.

We are pleased to see that our observations about the number of hyperbolic summands in EKL forms can indeed be generalized and refined to the inequalities of Eisenbud, Levine, and Teissier [2]. We believe our method of proof for establishing the exact number of hyperbolic forms that must appear in an EKL form of rank 5 can be of use to tighten the inequalities of Eisenbud and Levine. We hope that our observation that not all automorphisms of spheres are representable as local degrees in motivic homotopy theory is of interest to other researchers in the field.

We do believe we contribute some new results to the subject. It appears that our verification that the bounds of Eisenbud and Levine are tight in the specific case of EKL forms arising from maps of the plane $f : \mathbb{A}^2 \to \mathbb{A}^2$ with rank 4 and 9 is new. The product rule is the key idea to produce the examples that show the bounds are tight.
An algebraic proof of the product rule was given by [5], which we revisit with a few minor corrections. We also obtain a complete classification of the quadratic forms that are realizable as local degrees over finite fields of odd characteristic. The applications listed to local degrees of real maps were certainly known to Eisenbud and Levine [2] and Arnold [1], but we include them to round out the story.

Acknowledgements

We thank the Center for Advanced Study in Oslo for their hospitality, where we were able to complete much of this work and where we had many helpful discussions with Sabrina Pauli. We are also very grateful to Kirsten Wickelgren who suggested the applications of our results in section 6.3 and her enthusiastic support for our project. We are also grateful for the support from the Motivic Hopf Equations project RCN no. 250399.

Notation

We make heavy use of the notation and results from the work of Kass and Wickelgren [4], and refer the reader there for a more thorough overview. Write \( \mathbb{A}^n = \mathbb{A}^n_k \) for affine \( n \)-space over the field \( k \). If \( f: \mathbb{A}^n \to \mathbb{A}^n \) is a morphism of affine spaces over \( k \), we represent \( f \) with coordinate functions \( f = (f_1, \ldots, f_n) \) where each \( f_i \) is a polynomial \( f_i \in k[x_1, \ldots, x_n] \). We will write \( P = k[x_1, \ldots, x_n] \) for the polynomial ring over \( k \) in \( n \) variables and \( m = (x_1, \ldots, x_n) \) the maximal ideal corresponding to the origin. The local ring of \( \mathbb{A}^n \) at 0 is \( P_0 = k[x_1, \ldots, x_n]_m \), and we write \( Q_0(f) = P_0/(f_1, \ldots, f_n) \) for the local ring of \( f \) at 0. The map \( f \) is said to have an isolated zero at 0 if \( Q_0(f) \) is a finite dimensional vector space over \( k \). We write \( E = E(f) = E_0(f) \in Q_0(f) \) for the distinguished socle element of \( f \) at the origin. It is described by first obtaining expressions \( f_i(x) = f_i(0) + \sum_{j=1}^{n} a_{ij} x_j \) with polynomials \( a_{ij} \in P \) and then taking \( E = \det(a_{ij}) \).

2 Computations of local degrees

Let \( k \) denote an arbitrary field with characteristic different from 2. Kass and Wickelgren remark in [4, Remark 2 and Lemma 4] that the socle of \( Q_0(f) \) is equal to the annihilator of the maximal ideal. Moreover, \( E \) generates the socle of \( Q_0(f) \) if \( f \) has an isolated zero at the origin. This enables Kass and Wickelgren to make the following definition [4, Lemma 6 and Definition 7]:
Definition 1 Let $f : \mathbb{A}^n \to \mathbb{A}^n$ be a map with isolated zero at 0. Every linear functional $\phi : Q_0(f) \to k$ defines a symmetric bilinear form $\beta_\phi$ on $Q_0(f)$ by the formula $\beta_\phi(x,y) = \phi(x \cdot y)$. Any two linear functionals $\phi$ and $\phi'$ which satisfy $\phi(E) = \phi(E') = 1$ in fact have isometric bilinear forms $\beta_\phi \cong \beta_{\phi'}$. We may now define the EKL form of $f$ at 0, denoted by $w_0(f)$, to be the class of the symmetric bilinear form $\beta_\phi$ on $Q_0(f)$ in $GW(k)$ for any $k$-linear function $\phi : Q_0(f) \to k$ satisfying $\phi(E) = 1$. The form $\beta_\phi$ is in fact non-degenerate and we say the rank of $w_0(f)$ is the rank of the symmetric bilinear form $\beta_\phi$, which is just the dimension of $Q_0(f)$ as a $k$-vector space. As we assume the characteristic of $k$ is not 2, symmetric bilinear spaces and quadratic spaces are equivalent; we freely consider $\beta_\phi$ as both a symmetric bilinear form and a quadratic form without any distinction.

The observation that $E$ generates the annihilator of $Q_0(f)$ leads to our first result.

Theorem 2 Let $f : \mathbb{A}^n \to \mathbb{A}^n$ be a map with an isolated zero at 0. If the dimension of $Q_0(f)$ as a $k$-vector space is at least 2, then $\mathbb{H}$ is a direct summand of the EKL class $w_0(f)$.

Proof The distinguished socle element $E \in Q_0(f)$ generates the annihilator of the ideal $m = (x_1, ..., x_n)$ in $Q_0(f)$. If we assume that $E \notin m$, then $E$ is a unit in $Q_0(f)$. So as $E$ annihilates each $x_i$, the equations $E \cdot x_i = 0$ in $Q_0(f)$ imply $x_i = 0$ in $Q_0(f)$. Hence $Q_0(f)$ is spanned by 1, and $\dim_k Q_0(f) \leq 1$. We therefore conclude $E \in m$. Hence in choosing a $k$-linear function $\phi : Q_0(f) \to k$ we are free to take $\phi(1) = 0$. Now, the symmetric bilinear form $\beta_\phi$ is defined by $\beta_\phi(b) = \phi(b \cdot b)$ and [4, Lemma 6] shows that $\beta_\phi$ is nondegenerate. But now, $\beta_\phi(1) = \phi(1 \cdot 1) = 0$, that is, 1 is a non-trivial isotropic vector. Witt proves in [14, Satz 5] that under these circumstances, the quadratic form $\beta_\phi$ admits $\mathbb{H}$ as a direct summand. 

In Lemmas 3 through 9 we collect some basic calculations of EKL forms. These have appeared in the work of others, such as Pauli, Kass–Wickelgren, McKean, etc. We include the statements and proofs for completeness as they provide, in particular, concrete examples of EKL forms in low degrees. Lemma 5 shows that there is an EKL form $w_0(f) = \mathbb{H}$ of rank two and an EKL form of rank 3 with $w_0(f) = \mathbb{H} \oplus \langle a \rangle$ for a unit $a \in k^\times$, while Lemma 3 and Lemma 8 show that there are EKL forms of rank 4 of either form $\mathbb{H} \oplus \mathbb{H}$ or $\mathbb{H} \oplus \langle a, b \rangle$ with arbitrary units $a, b \in k^\times$. We will extend this list in the next section. Lemma 3 will provide examples for the study of EKL forms over finite fields in section 6.2.
Lemma 3 For any constants $a, b \in k^\times$, the map $f : \mathbb{A}^2 \to \mathbb{A}^2$ given by $f_1 = xy$, $f_2 = ax^2 - by^2$ and $\phi : Q_0(f) \to k$ a $k$-linear function with $\phi(E) = 1$, the associated quadratic form $\beta_\phi$ is congruent to the diagonal form $\langle 1, -1, -a, -b \rangle$.

Proof Use the graded reverse lexicographic ordering on $k[x, y]$ with $x > y$. The $S$-polynomial of $f_1$ and $f_2$ is $S(f_1, f_2) = \frac{b}{a}y^3$, which yields a Gröbner basis $(xy, ax^2 - by^2, y^3)$ for the ideal $(f_1, f_2) \subseteq k[x, y]$. As both $x^3$ and $y^3$ are in the ideal $(f_1, f_2)$, the quotient ring $k[x, y]/(f_1, f_2)$ is a local ring with maximal ideal $(x_1, x_2)$. By basic Gröbner basis theory, the ring $Q_0(f) = k[x, y]/(f_1, f_2)$ has as a $k$-basis $\{1, y, y^2, x\}$. One calculates $E = -by^2$, and so we may take $\phi(y^2) = -b^{-1}$ and declare $\phi$ to vanish on $1, x$, and $y$. Using the ordered basis $\{1, y, y^2, x\}$, the matrix for the quadratic form $\beta_\phi$ is

$$
\begin{pmatrix}
0 & 0 & -b^{-1} & 0 \\
0 & -b^{-1} & 0 & 0 \\
-b^{-1} & 0 & 0 & 0 \\
0 & 0 & 0 & -a^{-1}
\end{pmatrix},
$$

which is congruent to the diagonal form $\langle 1, -1, -a, -b \rangle$. \qed

Lemma 5 For any unit $a \in k^\times$, the map $f : \mathbb{A}^1 \to \mathbb{A}^1$ given by $f_1 = ax^n$, with $n \geq 2$, the EKL class of $f$ is $w_0(f) = \frac{n}{2} \mathbb{H}$ when $n$ is even and $w_0(f) = \frac{n-1}{2} \mathbb{H} \oplus \langle a \rangle$ when $n$ is odd.

Proof The calculation is straightforward. The local ring $Q_0(f) \cong k[x]/(x^n)$ has $\{1, x, \ldots, x^{n-1}\}$ as a $k$-basis, and $E = ax^{n-1}$. Define $\phi$ by $\phi(x^{n-1}) = a^{-1}$ and $\phi(x^i) = 0$ for $i < n - 1$. The matrix of the bilinear form $\beta_\phi$ is easily seen to be

$$
\begin{pmatrix}
0 & \cdots & 0 & a^{-1} \\
0 & \cdots & a^{-1} & 0 \\
\vdots & \vdots & \vdots & \vdots \\
a^{-1} & \cdots & 0 & 0
\end{pmatrix},
$$

which is congruent to the diagonal form claimed in the lemma. \qed

Remark 7 Lemma 5 gives a map $f : \mathbb{A}^1 \to \mathbb{A}^1$ in one variable, say $f \in k[x_1]$, that yields the EKL form $\frac{n}{2} \mathbb{H}$ or $\frac{n-1}{2} \mathbb{H} \oplus \langle a \rangle$. We can extend this map to a map $g : \mathbb{A}^n \to \mathbb{A}^n$ for any $n \geq 2$ as follows: take $g_1 = f(x_1)$ and $g_i = x_i$ for all $2 \leq i \leq n$. It is straightforward to verify that $w_0(f) \cong w_0(g)$, so although $w_0(g)$ arises from a map of $n$-space, it is effectively a one dimensional example. We give a general procedure for describing when an EKL form can be realized as an EKL form using fewer variables in Theorem 15.
Lemma 8 For any units \( a, b \in k^\times \), the map \( f : \mathbb{A}^2 \to \mathbb{A}^2 \) given by \( f_1 = xy \), \( f_2 = ay^n - bx^2 \) for \( n \geq 4 \) and \( n \) even, the EKL class of \( f \) is \( w_0(f) = \frac{n}{2} \mathbb{H} + \langle a, b \rangle \).

**Proof** A Gröbner basis is determined by calculating \( S \)-polynomials, and we must only add \( S(f_1, f_2) = \frac{2}{3}x^3 \) to the set \( \{ f_1, f_2 \} \) to get a Gröbner basis of the ideal \( (f_1, f_2) \). We have \( Q_0(f) \cong k[x, y]/(f_1, f_2) \) as the latter ring is a local ring, which is easily seen because both \( x^3 \) and \( y^{n+1} \) are in the ideal \( (f_1, f_2) \). A \( k \)-basis for \( Q_0(f) \) is then given by \( \{ x, x^2, y, y^2, \ldots, y^n \} \). We calculate \( E = ay^n + bx^2 \) in \( Q_0(f) \). Hence we define \( \phi \) so that \( \phi(x^3) = b^{-1} \) and require \( \phi \) to vanish on the other elements in our chosen basis.

The resulting matrix of the bilinear form \( \beta_\phi \) consists of two blocks: a \( 3 \times 3 \) block that is anti-diagonal with each anti-diagonal term equal to \( b^{-1} \) and an \( n - 1 \times n - 1 \) block that is anti-diagonal with each anti-diagonal entry equal to \( a^{-1} \). It is now straightforward to see that after diagonalizing this matrix, the resulting quadratic form is the one claimed in the lemma.

Lemma 9 For any units \( a, b \in k^\times \), the map \( f : \mathbb{A}^2 \to \mathbb{A}^2 \) given by \( f_1 = xy \) and \( f_2 = -bx^m + ay^n \) with \( n \geq m \geq 2 \) and both \( n \) and \( m \) even yields EKL class \( w_0(f) = \frac{m}{2} \mathbb{H} + \frac{n-2}{2} \mathbb{H} + \langle a, b \rangle \).

**Proof** The same line of argument we used for the proofs of Lemmas 3 and 8 yields the result.

Lemma 10 Let \( f : \mathbb{A}^n \to \mathbb{A}^n \) be a map with an isolated zero at 0, and suppose that \( \dim Q_0(f) = N \geq 1 \). Then the ideal \( (f_1, \ldots, f_n) \) in \( P_0 = k[x_1, \ldots, x_n, \phi(x_1, \ldots, x_n)] \) contains \( (x_1, \ldots, x_n)^N \). The one variable case shows that the exponent \( M = N \) with \( (x_1, \ldots, x_n)^M \subseteq (f_1, \ldots, f_n) \) is the biggest possible in general.

**Proof** Let \( x^\alpha = x_{i_1}x_{i_2} \cdots x_{i_N} \) be a monomial of degree \( N \), where the indices may be repeated and \( 1 \leq i_j \leq n \). The set \( \{ 1, x_{i_1}, x_{i_1}x_{i_2}, \ldots, x^\alpha \} \) must be linearly dependent in \( Q_0(f) \), as it contains \( N + 1 \) elements. Hence there is some linear relation \( \sum_{j=0}^N a_j x_{i_1} \cdots x_{i_j} = 0 \) in \( Q_0(f) \). Let \( m \) be the smallest index for which \( a_m \) is nonzero. We must have \( m \geq 1 \) as \( \dim Q_0(f) \geq 1 \). Then

\[
(11) \quad x_{i_1} \cdots x_{i_m} \left( \sum_{j=m}^N a_j x_{i_1} \cdots x_{i_m} \right) = 0
\]

implies that \( x_{i_1} \cdots x_{i_m} = 0 \) in \( Q_0(f) \), as the other factor is a unit in \( k[x_1, \ldots, x_n, \phi(x_1, \ldots, x_n)] \).

The result follows from this observation.
Lemma 12 Let \( f : \mathbb{A}^n \to \mathbb{A}^n \) be a map with an isolated zero at 0 and suppose \( \dim_k Q_0(f) = N \). If the map \( g : \mathbb{A}^n \to \mathbb{A}^n \) satisfies \( f_i - g_i \in (x_1, \ldots, x_n)^{N+1} \) in \( P_0 \) for all \( i \), then the ideals \((f_1, \ldots, f_n)\) and \((g_1, \ldots, g_n)\) are equal in \( P_0 \) and the EKL classes of \( f \) and \( g \) agree, i.e., \( w_0(f) = w_0(g) \).

Proof This result is essentially [4, Lemma 17]. To summarize their argument, the ideal \((f_1, \ldots, f_n)\) is shown to be equal to \((g_1, \ldots, g_n)\) by using Nakayama’s lemma; hence \( Q_0(f) = Q_0(g) \). Then they verify that the distinguished socle elements \( E(f) \) and \( E(g) \) are equal as follows. Write \( g_i = \sum a_{ij}(g)x_j \) so that \( E(g) = \det(a_{ij}(g)) \), then the condition \( f_i - g_i \in (x_1, \ldots, x_n)^{N+1} \) implies that the matrices \((a_{ij}(f))\) and \((a_{ij}(g))\) agree modulo \((x_1, \ldots, x_n)^N\), hence \( E(f) \) and \( E(g) \) agree. It now follows that the EKL classes of \( f \) and \( g \) agree (see [4, Definition 7]).

Lemma 13 Let \( f = (f_1, \ldots, f_n) : \mathbb{A}^n \to \mathbb{A}^n \) be a map with an isolated zero at 0. Then for any polynomial \( h \in k[x_1, \ldots, x_n] \) and any distinct indices \( i \) and \( j \), the polynomial maps \( f \) and \( f' = (f_1, \ldots, f_i + h \cdot f_j, \ldots, f_n) \) give isomorphic EKL classes.

Proof It is clear that the maps \( f \) and \( f' \) define the same local rings \( Q_0(f) = Q_0(f') \), so it is only a matter of verifying that the maps \( f \) and \( f' \) yield the same distinguished socle element \( E \). If we have \( f_i = \sum a_{ij}x_j \) so that \( E(f) = \det(a_{ij}) \), then \( E(f') \) is determined by first performing the elementary row operation of adding \( h \) times the \( j \)th row to the \( i \)th row modulo \((x_1, \ldots, x_n)^N\), hence \( E(f) \) and \( E(g) \) agree. It now follows that the EKL classes of \( f \) and \( f' \) agree.

Lemma 14 Let \( f = (f_1, \ldots, f_n) : \mathbb{A}^n \to \mathbb{A}^n \) be a map with an isolated zero at 0 and let \( A : \mathbb{A}^n \to \mathbb{A}^n \) be a linear isomorphism. Then \( Q_0(f) \cong Q_0(A \circ f) \) and the EKL classes of \( f \) and \( A \circ f \) differ by multiplication by \( \det(A) \).

Proof Express \( A \) as \( A = (a_{11}x_1 + \ldots + a_{1n}x_n, \ldots, a_{n1}x_1 + \ldots + a_{nn}x_n) \) with \( a_{ij} \in k \) so that

\[
A \circ f = \left( \sum_{k=1}^{n} a_{1k}f_k, \ldots, \sum_{k=1}^{n} a_{nk}f_k \right).
\]

It is clear that the ideals \((f_1, \ldots, f_n)\) and \((\sum_{k=1}^{n} a_{1k}f_k, \ldots, \sum_{k=1}^{n} a_{nk}f_k)\) agree in \( P \); hence the local rings \( Q_0(f) \) and \( Q_0(A \circ f) \) are equal. We now verify that the distinguished socle elements of \( f \) and \( A \circ f \) at 0 agree:
Let $b_{ij} \in P$ be polynomials such that $f_i(x) = \sum_{j=1}^{n} b_{ij} x_j$ for each $i$. Composing $f$ with $A$ then yields

$$(A \circ f)_i = \sum_{k=1}^{n} a_{ik} f_k = \sum_{k=1}^{n} a_{ik} \sum_{j=1}^{n} b_{kj} x_j = \sum_{j=1}^{n} \left( \sum_{k=1}^{n} a_{ik} b_{kj} \right) x_j.$$潮

Since we have $E(f) = \det(b_{ij})$ by definition of $E$, it follows that $E(A \circ f) = \det(A \cdot (b_{ij})) = \det(A) E(f)$. Note that $\det(A) \in k^\times$ is a unit. Now, given a $k$-linear function $\phi: Q_0(f) \to k$ so that $\phi(E(f)) = 1$, define $\tilde{\phi}: Q_0(A \circ f) \to k$ by $g \mapsto \det(A)^{-1} \phi(g)$. This is $k$-linear and maps $E(A \circ f)$ to 1, so we can use it to compute the EKL-class of $A \circ f$, and we get $w_0(A \circ f) = \det(A)^{-1} w_0(f)$. $\square$

We are now ready to prove a key technical result that will allow us to reduce dimensions in the following sections.

**Theorem 15** Suppose $f: \mathbb{A}^n \to \mathbb{A}^n$ is a map with an isolated zero at 0 and suppose that the rank of $Q_0(f)$ is $N \geq 1$. If the ideal $(f_1, \ldots, f_n)$ is not contained in $(x_1, \ldots, x_n)^2 \subseteq k[x_1, \ldots, x_n]$, then we can eliminate a variable in the description of $Q$. That is, there is a map $g: \mathbb{A}^{n-1} \to \mathbb{A}^{n-1}$ with isolated zero at 0 and $Q_0(g) \cong Q_0(f)$. Furthermore, the EKL classes of $f$ and $g$ differ only by multiplication by a unit.

**Proof** Recall that we write $P$ for the polynomial ring $k[x_1, \ldots, x_n]$, $m$ for the maximal ideal $(x_1, \ldots, x_n)$, and $P_0$ for the local ring $P$ localized at $m$. We study modifications of the generators of the ideal $(f_1, \ldots, f_n)$ until we are able to eliminate a variable. We can eliminate all terms of degree greater than $N$ in the polynomials $f_1, \ldots, f_n$ without modifying the ideal or the EKL class by Lemma 12. Assume this is done, and write $f_i = \sum_{j=1}^{N} f_{ij}$ where $f_{ij}$ is a homogeneous polynomial of degree $j$.

Without loss of generality, we may assume $f_{11}$ is non-zero, as we have assumed that some $f_i$ has a non-zero linear term. Find a linear isomorphism $A: \mathbb{A}^n \to \mathbb{A}^n$ that will transform $f_{11}$ into $x_1$. The EKL classes of $f$ and $f \circ A$ differ only by multiplication of a unit by Lemma 14, so we may assume $f_{11} = x_1$ from now on.

By adding multiples of $f_1$ to the other polynomials $f_2, \ldots, f_n$ and then removing all terms of degree greater than $N$, we may eliminate all of the monomials that are divisible by $x_1$ from $f_2, \ldots, f_n$. Write $g_2, \ldots, g_n$ for the resulting polynomials in $k[x_2, \ldots, x_n]$ obtained from this procedure. It follows that $(f_1, \ldots, f_n) = (f_1, g_2, \ldots, g_n)$ and also the EKL classes agree by Lemmas 13 and 12.

We now produce a polynomial $h \in k[x_2, \ldots, x_n]$ that satisfies $x_1 - h \in I$. We do this by showing that every monomial $x^\alpha$ that is divisible by $x_1$ admits a polynomial
h_α ∈ k[x_2, ..., x_n] for which x_α^m - h_α ∈ I. We use a downward induction argument, observing that the claim is true when the degree of x_α is at least N by taking h_α = 0 as m^N ⊆ I.

Assume the result is now true for all monomials x_α of total degree i + 1 that are divisible by x_1 and consider x_α of total degree i that is divisible by x_1. We can then consider the member of I

\[ \frac{x_α}{x_1} f_1 = \frac{x_α}{x_1} f_{N-1} + \cdots + x_α \in I. \]

All of the terms except x_α have degree at least i + 1. Hence the induction hypothesis may be used to replace all of the terms divisible by x_1 with a polynomial in k[x_2, ..., x_n]. This then yields an expression x_α - h_α ∈ I where h_α ∈ k[x_2, ..., x_n].

The ideals (f_1, f_2, ..., f_n) and (x_1 - h, g_2, ..., g_n) agree in the local ring P_0 = k[x_1, ..., x_n]_m. Furthermore, the maps (f_1, ..., f_n) and (x_1 - h, g_2, ..., g_n) define the same distinguished socle element up to a unit in P_0. The evaluation map ψ : P_0 → k[x_2, ..., x_n](x_2, ..., x_n) defined by φ(x_1) = g_1 and φ(x_i) = x_i otherwise induces an isomorphism on local rings ψ : Q_0(f) → Q_0(g), where g = (g_2, ..., g_n). It is now straightforward to see that the distinguished socle element E(x_1 - h, g_2, ..., g_n) maps under ψ to u · E(g_2, ..., g_n) for some unit u. Thus the EKL classes agree up to a unit and we are done.

**Remark 16** The previous theorem is inspired by the proof of [6, Lemma 5.7] and serves as a generalization of McKean’s result to higher dimensions. We thank Sabrina Pauli for bringing McKean’s paper to our attention.

**Lemma 17** Let f : \( \mathbb{A}^n \rightarrow \mathbb{A}^n \) be a map with isolated zero at 0 and assume that the ideal (f_1, ..., f_n) is contained in (x_1, ..., x_n)^2. Then the dimension of Q_0(f) is at least 2^n.

**Proof** This result follows from [3, §12.4] and the relevant result is clearly stated on [3, Chapter 12, Notes and References, page 234].

The two results above show that all EKL classes with rank less than 8 can be reduced to the planar or 2-variable case.

---

1As x_1 - h ∈ (f_1, ..., f_n), there is an equation x_1 - h = \( \sum \frac{a_i}{b_i} f_i \), where a_i, b_i ∈ P and the b_i are units. Multiply through by a common denominator; upon relabeling coefficients, we get an equation B(x_1 - h) = \( \sum a_i f_i \) in P. Modulo (x_2, ..., x_n) the equation is equivalent to Bx_1 = a_1 f_1. Since B is a unit, Bx_1 has a non-zero linear term. Thus a_1 f_1 must have a non-zero linear term too, and this can happen only if a_1 has a non-zero constant term. Thus a_1 is a unit in P_0. From this, we can finally obtain the expression f_1 = \( \frac{B}{a_1}(x_1 - h) - \sum_{i \neq 1} \frac{a_i}{a_1} f_i \).

2Write out the matrices that define E in both cases. Note that as f_i = g_i for i ≥ 2, only the first row of the two matrices can be different. But the first column of both matrices has only one non-zero entry, and it is a unit because both f_1 and x_1 - h have linear term x_1.
3 EKL classes of fixed rank

We will now address the question of which quadratic forms are representable as EKL forms. This question depends on the base field $k$, but we investigate the question for a general field $k$ below. We have already seen that any EKL form $w_0(f)$ with rank at least 2 necessarily has a hyperbolic summand. We have also seen that there are rank 4 EKL classes with exactly one hyperbolic summand in Lemma 3 and also some with two hyperbolic summands in Lemma 8. What then is the minimal number of hyperbolic forms that an EKL class of rank $n$ must contain as a summand over a general field? The next case to analyze is when the rank of $w_0(f)$ is 5. The following table summarizes the cases we know including our main result on rank 5 of Theorem 18.

| Rank | EKL form type   |
|------|----------------|
| 1    | $\langle a \rangle$ |
| 2    | $\mathbb{H}$ |
| 3    | $\mathbb{H} + \langle a \rangle$ |
| 4    | $\mathbb{H} + \langle a, b \rangle$ |
| 5    | $2\mathbb{H} + \langle a \rangle$ |
| 6    | ? |

Table 1: This is a list of the possible EKL forms of a given rank. In the EKL form type, the constants $a$ and $b$ are arbitrary units in the ground field. In particular, in the rank 4 case, it is possible to take $b = -a$ so that the EKL class is $2\mathbb{H}$.

Theorem 18 Let $f : \mathbb{A}^n \to \mathbb{A}^n$ be a map with isolated zero at 0, and suppose further that the rank of $w_0(f)$ is 5. Then $w_0(f) \cong 2\mathbb{H} \oplus \langle a \rangle$ for some unit $a$.

Proof By Theorem 15, Lemma 17, and our assumption that the rank of $w_0(f)$ is 5, we need only analyze the case of a function $f : \mathbb{A}^n \to \mathbb{A}^n$ where $n$ is 1 or 2. The one variable case was handled in Lemma 5, so we assume now that $f = (f_1, f_2) : \mathbb{A}^2 \to \mathbb{A}^2$ has an isolated zero at 0, the rank of $w_0(f)$ is 5, and $(f_1, f_2) \subseteq m^5$.

The local ring $Q_0(f)$ is isomorphic to the ring $P/((f_1, f_2) + m^5)$, and so we may study its structure by studying the structure of a Gröbner basis for the ideal $(f_1, f_2) + m^5$. There are only a few possibilities of the leading terms in a Gröbner basis in the 2 variable case that give a dimension of 5. We list them in Figure 1.

The crux of the argument is to find a subspace $\text{Span}\{h_1, h_2\} \subseteq Q_0(f)$ that is totally isotropic, which then guarantees that $2\mathbb{H}$ is a summand of $w_0(f)$ (see Scharlau for a more general result [10, Theorem 4.5.]). In our case, the two-dimensional subspace...
Figure 1: From left to right, top to bottom, we list the leading terms of generators for the Gröbner basis. (1) $y^5, x$; (2) $y^4, xy, x^2$; (3) $y^3, xy^2, x^2$; (4) $y^3, xy, x^3$; (5) $y^2, x^2y^2, x^3$; (6) $y^2, xy, x^4$; (7) $y, x^5$.

Span{${h_1, h_2}$} is totally isotropic if $\phi(h_1 \cdot h_1) = \phi(h_1 \cdot h_2) = \phi(h_2 \cdot h_2) = 0$. We manage to do one better and find {${h_1, h_2}$} which satisfy

\begin{equation}
    h_1^2 = h_2^2 = h_1h_2 = 0 \text{ in } Q_0(f).
\end{equation}

The proof now proceeds by a case-by-case analysis in Lemma 20.

**Lemma 20** We consolidate a case-by-case analysis of the ring structure of the local rings with Gröbner basis of type (1)–(7) found in figure 1. In particular, the local ring $Q_0(f)$ contains a linearly independent subset {${h_1, h_2}$} which satisfies $h_1^2 = h_2^2 = h_1h_2 = 0$.

**Proof** As described above, we only need to consider maps $f : \mathbb{A}^2 \to \mathbb{A}^2$ with $(f_1, f_2) \subseteq m^2$. Express the polynomials $f_1$ and $f_2$ as a sum of homogeneous polynomials as follows: $f_1 = f_{1,5} + \cdots + f_{1,2}$ and $f_2 = f_{2,5} + \cdots + f_{2,2}$. We are assuming that the intersection multiplicity of $V(f_1)$ and $V(f_2)$ at 0 is 5. This can only happen when the
projective tangent cones meet in exactly one point. This necessitates that both \( f_{1,2} \) and \( f_{2,2} \) split as a product of lines defined over the ground field and share exactly one factor. We can thus compose with an invertible linear transformation to modify \( f_{1,2} \) to \( xy \) and \( f_{2,2} \) to \( x(ax + by) \). This modification will only affect the EKL class by scalar multiplication by a unit by Lemma 14.

We now assume that \( f_{1,2} = xy \) and \( f_{2,2} = ax^2 + bxy \). But by adding \(-bf_1\) to \( f_2 \) we do not change the EKL class and obtain \( f_{1,2} = xy \) and \( f_{2,2} = ax^2 \). It must be that \( a \neq 0 \) for otherwise the rank of the EKL class would be at least 6.

We now proceed to our case-by-case analysis with the reduction above performed.

First note that cases (1) and (7) are not permitted as the Gröbner basis structure implies \( I = (f_1, f_2) + m^5 \) is not contained in \( m^2 \).

Case (2): We know that the ideal \( (f_1, f_2) + m^5 \) has a Gröbner basis of the form

\[
g_1 = y^4 + ax^3 + bx^2y + cxy^2 + dy^3 + ex^2 + fxy + gy^2 \\
g_2 = xy + hy^2 \\
g_3 = x^2.
\]

Hence the ideal \( I = (f_1, f_2) \subseteq P_0 \) is equal to \((g_1, g_2, g_3)\), which we now investigate. The dimension of \( I/mI \) must be at most 2 as the ideal \( I \) is generated by \((f_1, f_2)\) (this is a consequence of Nakayama’s Lemma). Thus the image of \( I/mI \) in \( m^2/m^3 \) is at most 2 dimensional, and our assumptions show that \( \{x^2, xy\} \) is in the image. So there can be no \( y^2 \) term in \( g_2 \). Thus the generators \((g_1, g_2, g_3)\) can be modified to give a new generating set of \( I \) of the form

\[
g_1 = y^4 + ay^3 \\
g_2 = xy \\
g_3 = x^2.
\]

for some new constant \( a \). Now observe that \( yg_1 \in I \) too, that is, \( y^5 + ay^4 \in I \) and we also know \( y^5 \in I \). In any event, \( y^4 \in I \). Thus we conclude \( m^4 \subseteq I \). Hence we have \( \{x, y^2\} \) a linearly independent subset of \( Q_0(f) \) satisfying (19), i.e., that is totally isotropic.

\(^3\)If the projective tangent cones were disjoint and \( f_{1,2} \) and \( f_{2,2} \) are non-zero, then the intersection multiplicity is exactly 4. If the projective tangent cones are identical, then \( f_{1,2} \) and \( f_{2,2} \) differ only by a scalar, and thus we can eliminate \( f_{2,2} \) by adding some multiple of \( f_{1,2} \) to \( f_2 \) without changing the intersection multiplicity. But then the intersection multiplicity is at least 6 in this case. Thus the only possibility is that \( f_{1,2} \) and \( f_{2,2} \) are both non-zero, split over \( k \), and share a common factor.
Case (3): The ideal \((f_1, f_2) + m^5\) has a Gröbner basis of the form
\[
\begin{align*}
g_1 &= y^3 + ax^2 + bxy + cy^2 \\
g_2 &= xy^2 + dy^3 + ex^2 + fxy + gy^2 \\
g_3 &= x^2 + hxy + iy^2.
\end{align*}
\]
Thus \(I = (f_1, f_2) = (g_1, g_2, g_3)\) in \(P_0\). By our assumption that the image of \(I/mI\) in \(m^2/m^3\) is generated by \(\{x^2, xy\}\), we can simplify the Gröbner basis to
\[
\begin{align*}
g_1 &= y^3 + ax \\
g_2 &= xy^2 + bxy \\
g_3 &= x^2 + cxy.
\end{align*}
\]
for some constants \(a, b, c\). Observe now that \(g_2\) factors as \(xy(y + b)\). If \(b \neq 0\), then \((y + b)\) is invertible in \(Q_0(f)\), hence we may conclude that \(\{xy, x^2, y^3\}\) generates \(I\), from which it follows that \(\dim_k Q_0(f) < 5\). Thus we need only consider the case when \(b = 0\). Now as \(yg_1 = y^4 + ax^2y \in I\) and \(xy^2 \in I\) it follows that \(y^4 \in I\). But now, \(x^2y^2 \in I\) and the set \(\{y^2, xy\}\) satisfies (19) and is totally isotropic in \(Q_0(f)\).

Case (4): The ideal \((f_1, f_2) + m^5\) has a Gröbner basis of the form
\[
\begin{align*}
g_1 &= y^3 + ax^2 + bxy + cy^2 \\
g_2 &= xy + dy^2 \\
g_3 &= x^2 + exy + fxy^2 + gy^3 + hx^2 + ixy + jy^2.
\end{align*}
\]
Thus \(I = (f_1, f_2) = (g_1, g_2, g_3)\) in \(P_0\). Because both \(xy\) and \(x^2\) are in the image of the map \(I/mI \to m^2/m^3\), we conclude that no \(y^2\) terms are permitted. Thus \(g_2 = xy\) and we may simplify the generators to
\[
\begin{align*}
g_1 &= y^3 + ax^2 \\
g_2 &= xy \\
g_3 &= x^3 + bx^2.
\end{align*}
\]
with \(a\) and \(b\) redefined constants. We now observe that \(yg_1 = y^4 + ax^2y\) is in the ideal, and thus so too is \(y^4\). Hence we conclude that \(m^4 \subseteq I\). Hence we have \(\{x^2, y^2\}\) satisfies (19) and is a totally isotropic subset of \(Q_0(f)\).

Cases (5) and (6): In these cases, we are forced to have \(y^2\) as a member of the Gröbner basis, which is not permitted by our assumption that the image of \(I/mI\) in \(m^2/m^3\) is generated by \(\{xy, x^2\}\).
4 The inequalities of Eisenbud, Levine, and Teissier

As was mentioned in the introduction, our calculations in Theorems 2 and 18 can be explained by the inequalities of Eisenbud, Levine, and Teissier in [2]. We present their results now and consider the implications for the use of EKL forms in motivic homotopy theory.

Eisenbud and Levine show that an EKL form has $n$ hyperbolic summands if and only if the local ring $Q_0(f)$ contains an ideal $I$ of dimension $n$ which satisfies $I^2 = 0$. When such an ideal is found, the dual ideal for $I$, denoted by $I^*$, is used to produce the hyperbolic subspace $I \oplus I^*$ of the EKL form. Thus the quadratic space $Q_0(f)$ with the quadratic form $w_0(f)$ decomposes as $Q_0(f) = I \oplus I^* \oplus D$, where $D$ is an anisotropic subspace, meaning that it contains no isotropic subspaces. Eisenbud and Levine state their results by describing how large the dimension of $D$ can possibly be.

**Theorem 21** The Eisenbud–Levine–Teissier inequality states that if $f : \mathbb{A}^n_k \to \mathbb{A}^n_k$ is a polynomial map which has an isolated zero at 0 so that $\dim_k Q_0(f) \geq 1$, then the dimension of the anisotropic part of the quadratic space $(Q_0(f), w_0(f))$ is bounded by:

\[
\dim_k D \leq \frac{(\dim_k Q_0(f))^{1-1/n}}{2}.
\]

The first inequality is tighter, but the latter has the advantage of being independent of $n$.

**Corollary 24** For a map $f : \mathbb{A}^n_k \to \mathbb{A}^n_k$ with an isolated zero at 0, it is an immediate consequence of the ELT inequality that the number of hyperbolic summands in $(Q_0(f), w_0(f))$ must at least be:

\[
\dim_k I \geq \frac{(\dim_k Q_0(f))^{1-1/n}}{2}.
\]

With these inequalities, we can extend the chart in Table 1 with the values in Table 2. Unfortunately, the case of rank 8 is unclear. It is possible that there is a 3 variable example with EKL form $2\mathbb{H} \oplus \langle a, b, c, d \rangle$. In the two variable case, the ELT inequality says that the only possible EKL forms are $3\mathbb{H} \oplus \langle a, b \rangle$.

It is unclear what exactly happens in rank 9. We have found an example over $\mathbb{R}$ with EKL form $3\mathbb{H} \oplus \langle 1, 1, 1 \rangle$, see Example 29. But does this mean that over a general field...
Table 2: This is a list of the possible EKL forms of a given rank. In the EKL form type, the constants $a$ and $b$ are arbitrary units in the ground field.

| Rank | EKL form type     |
|------|-------------------|
| 6    | $2\mathbb{H} \oplus \langle a, b \rangle$ |
| 7    | $3\mathbb{H} \oplus \langle a \rangle$ |
| 8    | ?                 |

$3\mathbb{H} \oplus \langle a, b, c \rangle$ is also always realizable as an EKL form, or only some proper subset of these? E.g., over $\mathbb{Q}$, we may indeed have $3\mathbb{H} \oplus \langle 3, 3, 3 \rangle$ representable as an EKL form, but that does not mean that $3\mathbb{H} \oplus \langle 3, 5, 7 \rangle$ is representable too. Can we fully describe the set of quadratic forms representable by EKL forms at 0?

## 5 Computational results

The process of computing the EKL class of a map $f : \mathbb{A}^n \to \mathbb{A}^n$ can be automated and performed by a computer. Sabrina Pauli [8] uses Macaulay2 to perform such computations over finite fields, for example. We have written a simple python program that calculates the EKL class of a map, which is available on Github [13]. In this section, we provide some experimental results that give upper bounds for the minimal number of hyperbolic summands that must appear in an EKL form of rank $n$. Table 1 gives the complete information of EKL forms up to rank 5, and in this section we will see how complicated it may be to extend this table in general.

**Definition 25** Let $n$ and $m$ be positive natural numbers and $k$ a field. Write $M(n, m; k)$ for the minimum number of hyperbolic summands appearing in rank $n$ EKL forms $w_0(f)$ for all possible maps $f : \mathbb{A}^m \to \mathbb{A}^m$ over the field $k$, and define $M(n)$ to be the minimum of $M(n, m; k)$ over the set of all possible $m$ and $k$. We also consider the numbers $N(n, m; k) = n - 2M(n, m; k)$ and $N(n) = n - 2M(n)$, which tell us the largest possible rank of a representative of $w_0(f)$ in the Witt ring, i.e., the rank of the “Grundform” of $w_0(f)$ [14, page 35].

Our work up until now has established the values of $M(n)$ for $n \leq 5$, which are: $M(1) = 0, M(2) = 1, M(3) = 1, M(4) = 1, M(5) = 2$.

A product rule for EKL forms was established by Knight, Swaminathan, and Tseng in [5, Theorem 13]. We believe that their argument to establish the product rule is correct. However, we noticed a few inaccuracies in the written proof in [5, Theorem
We provide a proof of the product rule following their argument for completeness. We do not claim any originality.

**Theorem 26** Let \( f, g : \mathbb{A}^n \to \mathbb{A}^n \) be maps with isolated zeros at the origin. The EKL form of the composition \( f \circ g \) is the product of the EKL forms of \( f \) and \( g \), i.e.,

\[
w_0(f \circ g) = w_0(f) \cdot w_0(g) \text{ in } GW(k).
\]

**Proof** We follow the proof by Knight, Swaminathan and Tseng with a minor correction. The idea is to add further variables and to compose with appropriate linear transformations to make \( f \) and \( g \) act on separate variables. So let \( \tilde{f}, \tilde{g} : \mathbb{A}^n \times \mathbb{A}^n \to \mathbb{A}^n \times \mathbb{A}^n \) be defined by sending \((x, y)\) to \((f(x), y)\) and \((g(x), y)\), respectively, where we write \((x, y)\) for \((x_1, \ldots, x_n, y_1, \ldots, y_n)\). Then we have \( w_0(\tilde{f}) = w_0(f) \) and \( w_0(\tilde{g}) = w_0(g) \) and it suffices to prove the claim for \( \tilde{f} \) and \( \tilde{g} \). The key tool is [5, Lemma 12] which states that for maps \( f \) and \( g \) as in the theorem and a unipotent linear transformation \( L : \mathbb{A}^n \to \mathbb{A}^n \) we have

\[
w_0(f \circ L \circ g) = w_0(f \circ g).
\]

Note that this statement agrees with Lemma 14 for the case that \( A = L \) is unipotent (and thus has determinant equal 1) and \( f \) or \( g \) being the identity.

Let \( I_n \) denote the \( n \times n \)-identity matrix. Consider the following three unipotent matrices:

\[
L_1 = \begin{pmatrix} I_n & 0 \\ -I_n & I_n \end{pmatrix}, \quad L_2 = \begin{pmatrix} I_n & I_n \\ 0 & I_n \end{pmatrix}, \quad L_3 = \begin{pmatrix} I_n & 0 \\ -I_n & I_n \end{pmatrix}.
\]

Then it follows from (27), i.e., [5, Lemma 12], that the following two compositions have the same EKL forms:

\[
\tilde{f} \circ \tilde{g} : (x, y) \mapsto (f(g(x)), y) \quad \text{and} \quad \tilde{f} \circ L_1 \circ \tilde{g} : (x, y) \mapsto (f(g(x)), -g(x) + y).
\]

Now we apply [5, Lemma 12] to the maps \( \tilde{f} \) and \((L_1 \circ \tilde{g})\) and the unipotent transformation \( L_2 \). This shows that the EKL forms of the maps

\[
\tilde{f} \circ L_1 \circ \tilde{g} : (x, y) \mapsto (f(g(x)), -g(x) + y)
\]

\[
\tilde{f} \circ L_2 \circ (L_1 \circ \tilde{g}) : (x, y) \mapsto (f(y), -g(x) + y)
\]

are equal. Next we apply [5, Lemma 12] to the maps \( \tilde{f} \) and \((L_2 \circ L_1 \circ \tilde{g})\) and the unipotent transformation \( L_3 \). This shows that the EKL forms of the maps

\[
\tilde{f} \circ L_2 \circ (L_1 \circ \tilde{g}) : (x, y) \mapsto (f(y), -g(x) + y)
\]

\[
\tilde{f} \circ L_3 \circ (L_2 \circ L_1 \circ \tilde{g}) : (x, y) \mapsto (f(y), -g(x))
\]

are equal as well. We denote the map \((x, y) \mapsto (f(y), -g(x))\) by \( f \times (-g) \). We have shown that \( w_0(\tilde{f} \circ \tilde{g}) \) equals \( w_0(f \times (-g)) \).
Now we compose \( f \times (-g) \) with the matrix \( A = \begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix} \) and deduce from Lemma 14 that \( f \times (-g) \) and \( A \circ (f \times (-g)) = g \times f \) have the same EKL class.\(^4\) Hence we have

\[
w_0(f \circ g) = w_0(\tilde{f} \circ \tilde{g}) = w_0(g \times f).
\]

It is straightforward to compute the EKL class of \( g \times f \) to be

\[
w_0(g \times f) = w_0(g) \cdot w_0(f) \quad \text{in} \quad GW(k),
\]

which concludes the proof.

From this, we can obtain some simple bounds for \( M(n, 2; k) \) and \( N(n, 2; k) \).

**Corollary 28** The set of quadratic forms that are realizable as EKL forms at 0 over \( k \) is a multiplicative submonoid of \( GW(k) \).

**Proof** The claim follows immediately from the product rule.\( \square \)

**Example 29** Consider the polynomials \( f = -x^3 - x^2 y + 4xy^2 + 2y^3 \) and \( g = 2x^3 - x^2 y - 5xy^2 - y^3 \). The EKL form of the map \( \langle f, g \rangle : \mathbb{A}^2 \rightarrow \mathbb{A}^2 \) considered over the base field \( \mathbb{Q} \) is the quadratic form \( \langle 6, 6, 3, -6, -6, 3, -6, 3 \rangle \cong 3\mathbb{H} + \langle 3, 3, 3 \rangle \), which was computed with the assistance of a computer. Hence for rank 9 EKL forms, we may only have 3 hyperbolic summands. Hence \( M(9, 2; k) \leq 3 \), i.e., \( N(9, 2; k) \geq 3 \).

**Proposition 30** Consider the map \( f = (xy, y^2 - x^2) \) studied in Lemma 3. Then the iterated composition \( f^{(n)} \) has EKL form

\[
w_0(f^{(n)}) = 2^{n-1}(2^n - 1)\mathbb{H} + 2^n(1)
\]

In particular, \( M(4^n, 2; k) \leq 2^{n-1}(2^n - 1) \), i.e., \( N(4^n, 2; k) \geq 2^n \).

Likewise, using the map \( f \) in Example 29, the product rule shows

\[
w_0(f^{(n)}) = \frac{9^n - 3^n}{2} \mathbb{H} + 3^n(1);
\]

hence \( N(9^n, 2; k) \geq 3^n \).

**Proof** The calculations follow immediately from the product rule.\( \square \)

\(^4\)Alternatively, one can apply \([5, \text{Lemma 12}]\) in three successive steps to the composition \( L_6 \circ L_5 \circ L_4 \circ (f \times (-g)) = g \times f \) where \( L_4, L_5, L_6 \) denote the unipotent matrices

\[
L_4 = \begin{pmatrix} I_n & -I_n \\ 0 & I_n \end{pmatrix}, \quad L_5 = \begin{pmatrix} I_n & 0 \\ I_n & I_n \end{pmatrix}, \quad L_6 = \begin{pmatrix} I_n & -I_n \\ 0 & I_n \end{pmatrix}
\]
such that their composition is \( L_6 \circ L_5 \circ L_4 = A \).
Computational evidence for small values of $n$ suggest that the bounds in Proposition 30 are in fact equalities: $N(9^n, 2; k) = 3^n$ and $N(4^n, 2; k) = 2^n$, suggesting the equation $N(p^{2n}, 2; k) = p^n$ holds. In fact, the general result of Eisenbud and Levine in [2, Theorem 3.9 (i)] gives the bound $N(n, 2; k) \leq \sqrt{n}$, which when combined with Proposition 30 gives the results $N(9^n, 2; k) = 3^n$ and $N(4^n, 2; k) = 2^n$ that we anticipated. Furthermore, we have observed that $N(3) = N(5) = 1$ and computational experiments suggest $N(7) = 1$ and $N(11, 2; k) = 1$ too. It is reasonable to conjecture that for odd primes $p$ that $N(p^n, 2; k) = 1$, and perhaps $N(p)=1$ holds more generally.

Eisenbud and Levine show that the bounds above are not tight when maps $f : \mathbb{A}^m \to \mathbb{A}^m$ are allowed for $m \geq 3$. In [2, Example, page 24] they produce an example $f : \mathbb{A}^4_\mathbb{R} \to \mathbb{A}^4_\mathbb{R}$ where $\dim Q_0(f) = 16$ where the signature of $w_0(f)$ is 6. That is, $N(16, 4; \mathbb{R}) \geq 6$ whereas our bound in the planar case is only $N(16, 2; k) \geq 4$.

6 Applications

6.1 Representability in motivic homotopy theory

For any map $f : \mathbb{A}^n \to \mathbb{A}^n$ with an isolated zero at 0, Kass and Wickelgren [4, Definition 11] construct a map in the motivic homotopy category $f_0 : \mathbb{P}^n/\mathbb{P}^{n-1} \to \mathbb{P}^n/\mathbb{P}^{n-1}$ that encodes the local behavior of $f$ at 0. To obtain a local degree in motivic homotopy theory, Kass and Wickelgren apply Morel’s $A^1$-Brouwer degree $\deg : [\mathbb{P}^n/\mathbb{P}^{n-1}] \to GW(k)$ to $f_0$ to obtain the class of a quadratic form, which we write as $\deg_{A^1}^0(f) = \deg(f_0)$. The main result of Kass and Wickelgren in [4] is that the local degree $\deg_{A^1}^0(f)$ defined using Morel’s degree map is equal to the class of the EKL form of $f$ at 0 in $GW(k)$. Note that Morel’s degree map is in fact an isomorphism when $n \geq 2$, so that algebraic results about EKL forms can be translated into statements about motivic homotopy theory.

**Theorem 31** Suppose $q \in GW(k)$ is a quadratic form with rank at least 2 that does not represent 0, that is, $q$ admits no non-zero vector $v$ for which $q(v) = 0$. Then there is no map $f : \mathbb{A}^n \to \mathbb{A}^n$ with an isolated zero at 0 for which $\deg_{A^1}^0(f) = q$ in $GW(k)$.

**Proof** This follows immediately from the identification of the local $A^1$-Brouwer degree with the EKL form of a map by Kass and Wickelgren, combined with Theorem 2. □
Corollary 32 If $-1$ is not a square in $k$, then the quadratic form $\langle 1, 1 \rangle$ is not representable as a local degree map under Morel’s $\mathbb{A}^1$-Brouwer degree isomorphism.

Because Morel’s degree homomorphism $\deg : [\mathbb{P}^n/\mathbb{P}^{n-1}, \mathbb{P}^n/\mathbb{P}^{n-1}] \to GW(k)$ is an isomorphism for $n \geq 2$, we can translate our results into statements about the set of motivic homotopy classes $[\mathbb{P}^n/\mathbb{P}^{n-1}, \mathbb{P}^n/\mathbb{P}^{n-1}]$. We give an example using our result about rank 5 EKL forms.

Theorem 33 Let $k$ be a field and consider a map $g : \mathbb{P}^n/\mathbb{P}^{n-1} \to \mathbb{P}^n/\mathbb{P}^{n-1}$ with $n \geq 2$. If the motivic Brouwer degree of $g$ is represented by a quadratic form $q$ of rank 5, then $g$ is $\mathbb{A}^1$-homotopy equivalent to a local degree map $f_0$ for some map $f : \mathbb{A}^n \to \mathbb{A}^n$ if and only if $q$ is of the form $2\mathbb{H} + \langle a \rangle$.

Proof This follows from the fact that Morel’s degree map is an isomorphism when $n \geq 2$ [7, Corollary 1.24] and our result on rank 5 EKL forms in Theorem 18.

Of course, similar results in rank 6 and 7 follow directly from the inequality of Eisenbud, Levine, and Teissier described in Theorem 21. In particular, in ranks 1, 3, 5, and 7 the discriminant of the EKL form contains all of the information of the local degree.

6.2 Finite fields

Over a finite field with odd characteristic, the problem of identifying the isometry class of a quadratic form in $GW(k) \cong \mathbb{Z} \oplus \mathbb{Z}/2$ is resolved simply by considering the rank and discriminant of the quadratic form. With this simple characterization, the lemmas of section 2 allow us to completely classify which quadratic forms arise as EKL classes.

Theorem 34 Let $\mathbb{F}_q$ be a finite field of odd characteristic. Every quadratic form over $\mathbb{F}_q$ is representable as an EKL class except for the rank 2 form with discriminant not equal to $-1 \in k^\times/k^{x^2}$.

Proof Lemma 5 shows that there is a map $f : \mathbb{A}^1 \to \mathbb{A}^1$ with EKL class $w_0(f) = \langle a \rangle$ for any unit $a$, which covers the rank 1 case. In rank 2, Theorem 2 shows that the only EKL class is $\mathbb{H}$, which has discriminant $-1$. Thus when $q \equiv 3 \mod 4$, the unit $-1$ is not a square, and so $\langle 1, 1 \rangle$ is not representable as an EKL class. When $q \equiv 1 \mod 4$, the unit $-1$ is a square class, and thus any rank 2 form with discriminant a non-square is not representable as an EKL class.
Any quadratic form of rank $2n + 1 \geq 3$ is representable as an EKL class because Lemma 5 shows that we can choose a map $f : \mathbb{A}^1 \to \mathbb{A}^1$ so that $w_0(f)$ has rank $2n + 1$ and discriminant $a$ for any unit $a \in k^\times$.

For a quadratic form of rank $2n \geq 4$, Lemma 3 shows that we can construct a map $f : \mathbb{A}^2 \to \mathbb{A}^2$ of rank $2n$ with discriminant $(-1)^{n-1}ab$ for any choice of units $a, b \in k^\times$. Hence we can realize both isometry classes of quadratic forms of rank $2n$ as EKL classes.

### 6.3 Singularities with specified Milnor number

Another avenue for applications for the structure of EKL forms that we have observed is to the study of isolated hypersurface singularities, following the work of Kass and Wickelgren [4]. In particular, our results produce restrictions on the way singularities can degenerate into nodes just by knowing the Milnor number of the singularity in the cases where the Milnor number is at most 5. We require the base field to have characteristic different from 2 in this section.

We refer the reader to Kass and Wickelgren [4, §8] and Pauli and Wickelgren [9, §6.2] for a more thorough discussion, but summarize the main points here. Let $X = \{ f = 0 \}$ be a hypersurface in $\mathbb{A}^n$ and assume that 0 is an isolated zero of its gradient, $\text{grad}(f) : \mathbb{A}^n \to \mathbb{A}^n$. We can then look at the local degree of $\text{grad}(f)$ at 0 as an invariant of the singularity of $f$ at 0. The Milnor number of $f$ at 0 is $\mu(f) = \dim_k Q_0(\text{grad}(f))$, and the enrichment to motivic homotopy theory is to take the $\mathbb{A}^1$-Milnor number of $f$ at 0 to be $\mu^{\mathbb{A}^1}(f) = \text{deg}_{0}^{\mathbb{A}^1}(\text{grad}(f))$.

Kass and Wickelgren study the family of deformations of the hypersurface $f$ that take the form $\{ f(x_1, ..., x_n) + \sum_i a_i x_i = t \}$, i.e., the fibers of the map $F = f + \sum_i a_i x_i : \mathbb{A}^n \to \mathbb{A}^1$. For a generic choice of $k$-point $(a_1, ..., a_n) \in \mathbb{A}^n(k)$, the hypersurfaces in this family (the fibers of the map) has only nodal singularities. Kass and Wickelgren prove in [4, Equation (6) and Corollary 45] that $\mu^{\mathbb{A}^1}(f)$ counts the number of nodal fibers of this family. To be more precise, if $f : \mathbb{A}^n \to \mathbb{A}^1$ is such that $\text{grad}(f)$ is finite and separable and 0 is the only singularity of $f$, then

$$
\mu^{\mathbb{A}^1}(f) = \sum_{x \text{ node of } F} \text{Tr}_{k(x)/k}\text{type}(x,f)
$$

where type$(x,f)$ is the $\mathbb{A}^1$-Milnor number of the singular point of the nodal fiber of $F$ corresponding to $x$.

Our results can now be applied by making assumptions on the Milnor number of the singularity of $f$ at 0 and inferring restrictions on what kinds of families of nodes
the singularity can degenerate into. The next theorem is the evident generalization of [9, Example 14] from the cusp—which has $\mathbb{A}^1$-Milnor number $\mathbb{H}$—to the case of any singularity with Milnor number 2.

**Theorem 36** Assume the characteristic of $k$ is not 2 and assume $-1$ is not a square in $k$. Consider any hypersurface $X = \{ f = 0 \}$ in $\mathbb{A}^n$ for which $\text{grad}(f)$ has an isolated zero at 0. If the Milnor number of $f$ at zero $\mu_0(f) = \dim_k Q_0(\text{grad}(f))$ is equal to 2, then if the singularity degenerates into a pair of $k$-rational nodes, it must be that the nodes have type $\langle a \rangle$ and $\langle -a \rangle$ for some unit $a \in k^\times$.

**Proof** This follows from [9, Theorem 4] and Theorem 2. □

Over the field of real numbers, the signature of the $\mathbb{A}^1$-Milnor number of a singularity encodes topological information about the Milnor fibers of the singularity. The work of Arnold [1] presents the relevant terminology and gives several results, which we briefly summarize here. We also suggest the reader look at van Straten and Warmt for an introduction and related results [11].

For $f : \mathbb{A}^n_\mathbb{R} \to \mathbb{A}^1_\mathbb{R}$ a map with an isolated singularity at 0, $B(0; \epsilon)$ a sufficiently small ball about the origin, and $0 < |\eta|$ sufficiently small, the real Milnor fibers of $f$ are the sets:

$$F_\eta = B(0; \epsilon) \cap f^{-1}(\eta)$$

The topology of these fibers is controlled by the signature of the $\mathbb{A}^1$-Milnor number of the singularity of $f$ at 0. In particular, Arnold [1, §§1–2] (compare with [11, Theorem 1.3]) calculates the reduced Euler characteristic (Euler characteristic minus 1) of the Milnor fibers to be:

$$\text{signature}(\mu^\mathbb{A}_0(f)) = -\tilde{\chi}(F_{-\eta}) = (-1)^{n-1}\tilde{\chi}(F_{\eta})$$

when $\eta > 0$.

From this result, the reduced Euler characteristics of the fibers $F_\eta$ must be between $-\mu(f)$ and $\mu(f)$. Our characterization of EKL forms shows that this naive bound can be improved, and for small enough Milnor numbers, the reduced Euler characteristic of these Milnor fibers can be completely determined.

**Theorem 37** Let $f : \mathbb{A}^m_\mathbb{R} \to \mathbb{A}^1_\mathbb{R}$ be a polynomial map with isolated singularity at 0 with Milnor number $n \geq 2$. Then the reduced Euler characteristic of the Milnor fibers is bounded in absolute value by $n - 2$. If $\mu(f) = 2$, then the reduced Euler characteristic of the Milnor fibers is 0. If the Milnor number is 3, 5, or 7, then the reduced Euler characteristic of the Milnor fibers is $\pm 1$. 

Representability of the motivic Brouwer degree

Proof This follows from the result of Arnold, stated in [11, Theorem 1.3] along with our main theorems 2, 18, and the ELT inequality in theorem 21.

The setup to this theorem was certainly known to Eisenbud and Levine in [2] and Arnold [1]. We do not claim any originality for this result. Similarly, the following theorem is one of the main results that Eisenbud and Levine sought to prove in their foundational paper [2].

Theorem 38 Let $f : \mathbb{A}^n_\mathbb{R} \to \mathbb{A}^n_\mathbb{R}$ be a polynomial map with an isolated zero at 0. If the rank of the EKL form of $f$ at 0 is 3, 5, or 7 then the local topological degree of $f$ at 0 is $\pm 1$. And if the rank of the EKL form of $f$ at 0 is 2, then the local topological degree of $f$ at 0 is 0.

Proof This follows from Eisenbud and Levine’s main result [2, Theorem 1.2], our main results, theorems 2, 18, and the Eisenbud–Levine–Teissier inequality in rank 7, see theorem 21.

The Eisenbud–Levine–Teissier inequality can of course be used to obtain more general bounds for the degree. Explicitly, Eisenbud and Levine state this in [2, Theorem 2.1] and give further geometric interpretations in [2, §2].
