Abstract

Background: Mental and psychological disorders are responsible for significant morbidity and disability worldwide. Results of World Mental Health Consortium demonstrate that common mental disorders are highly prevalent globally. Only a limited proportion of patients with psychiatric disorders attend the healthcare facilities, in severe condition. Treatment by unqualified medical practitioners and faith healers is a common practice, which significantly delay the proper treatment.

Methods: We conducted this survey at the psychiatry OPD at Jinnah Hospital Lahore from March 2015 to May 2015. 1000 study subjects of 14 -70 years of age from both genders were enrolled for this study randomly, who sought psychiatric opinion for first time.

Results: One hundred patients were examined, mean age of subjects was 31 years (SD + 15.02), with 53.0% females. More patients (60.0%) were first time recognized by their family members, remaining sought treatment by themselves. As per history 42.4% patients had consulted to Qualified Medical General Practitioners, 19.9% to Piers, 12.0% to Religious Clerics and 10.5% to Hakim, Fakir, Malang etc. and only 2.6% consulted to psychotherapist.

Conclusion: It is concluded that in our setting psychiatric illnesses are always recognized late and medical practitioners do not bother to obtain consultative opinion from psychotherapist.

Keywords: Mental illness, depression, treatment, hospital visits

Introduction

Mental disorders and their associated psychosocial disabilities are a source of considerable morbidity and impose a significant drain on national resources. The majority of the world’s 450 million people suffering from psychiatric morbidity live in developing countries, and less than 10% have access to mental healthcare(1). It is important for mental healthcare professionals to be aware and sensitive to spiritual dimensions of mental health (2). A recent study in assessing the implications of psychiatric phiralism for WHO search on mental health disorder examined patients in three forms of therapy for mental illness in South India, ayurvedic, allopathic and religious healing(3). The bulk of epidemiological research in Uganda has focused on primary care settings, where most psychiatric disorders are Non-psychotic (4,5). The reported prevalence rates vary widely, from 10% to nearly half of all primary care attendees (the quoted figures range from 10-25% of patients attending with a psychiatric problem, with or without a co-existing physical problem). The most common diagnoses are depression and anxiety (6,7,8).

A community study from rural Uganda by Orley and Wing found the following prevalence: Depression 9.3%, Anxiety 8.5%, Bipolar disorder 4.9% and Schizophrenia 1.5 % (9). In a study of households in the Kabarole district of Uganda, Kasoro and others found that 30.7% of adults had psychiatric disorders (10). On the basis of the UNHSS 2005/2006 Qualitative Module Report, the Uganda Bureau of Statistics found, for example, that 58% of all the households with disabled members (an estimated 7% of all households in Uganda), had at least one member with a mental disorder (11). Furthermore, it is possible that many patients with psychosis do not
spontaneously seek primary healthcare (12). A study in urban Tanzania the prevalence of common mental disorders was 48% (13). Patel and others found a prevalence of 40% in Harare (14). Study will reveal current trends and practices of health seeking behavior of patients suffering from psychiatric illness. The term mental illness is generally referred to mental health problems in adults (15). Significant disease load is attributed to mental illnesses globally and talking in terms of DALY (disability adjusted life years), a more reliable indicator, more than two fifth of total disabilities are due to mental illness (16). Out of the top ten leading causes of disabilities throughout the world, five are psychiatric illnesses (17).

In Pakistan number of studies have shown that many people attribute depression (which is a major psychiatric problem) to evil influences. Many parents believe in Jin, magic and evil eye for the mental illness of their child (18, 19). Studies have also shown that majority of the patients, who attend the spiritual healers are either uneducated or just had primary education (20, 21). This study was conducted to assess this aspect of our population so that steps could be taken for better provision of health facilities along with disease management and control (22). By permitting consideration of ‘secular’ spiritual activities and short-circuiting destructive arguments about beliefs, a valuable perspective can be applied to the whole field of mental healthcare (23). It follows that psychiatric care should routinely include a careful and sympathetic assessment or ‘spiritual screening’ (24).

Neuropsychiatric conditions together account for 10.96% of the global burden of disease as measured by disability-adjusted life years (DALY’s) (25).

In most countries, families bear a significant proportion of these economic costs because of the absence of public funded comprehensive mental health service networks (26).

The belief that mental illness is incurable or self-inflicted can also be damaging, leading to patients not being referred for appropriate mental healthcare (27). It is pertinent to study the perceptions, myths, beliefs and health-seeking behavior for mental health of population (28). Reasons for choosing a particular service help in understanding how the population perceives mental illnesses and responds to them (29). This knowledge can be helpful in developing community awareness programs so as to remove myths and misconceptions about mental illnesses and sensitize the people with the availability of various sources of help available in the community (30).

Methodology

Cross sectional descriptive study in Psychiatric OPD Jinnah Hospital Lahore was conducted on 100 subjects and Purposive sampling was done. Patient with age 14 - 70 years of both gender and Patients seeking psychiatric opinion for first time was included in this study. A structured questionnaire was designed containing information regarding health seeking practices of psychiatric patients. Data was entered and analyzed in SPSS ver: 17.0. Mean and standard deviation was calculated for numerical variable like age. Frequency and percentage will be calculated for qualitative variables like diagnosis, gender distribution, faith healers visits and reason for faith healer visits.

Results

Mean age of subjects was 31 years SD + 15.02, median age 27 and mode 18. Minimum ages of subjects were 10 years and maximum ages of subjects were 80 years. (Table No- 1) 67% urban and 33% rural 53.0 % were females and 47.0 % were males.

Table 1: Age of subjects

| Age of Respondents | Frequency | Percent |
|--------------------|-----------|---------|
| 14 - 30 years      | 60        | 60.0    |
| 31 - 60 years      | 32        | 32.0    |
| 60 years and above | 8         | 8.0     |
| Total              | 100       | 100.0   |

Education of subjects was found that 28.0 % of subjects were illiterate, 21% had attended primary school and 14.0% had attended secondary school. Among the respondents 36.0% were illiterate, 21.0% had attended primary school and 10.0% attended secondary school. (Table No.: 3).

Table 3: Educational status of subjects and respondents

| Education status | Education status of subject | Education status of respondent |
|------------------|-----------------------------|-------------------------------|
|                  | Frequency | Percent | Frequency | Percent |
| Illiterate       | 28        | 28.0    | 16        | 36.0    |
| Primary          | 12        | 12.0    | 7         | 7.0     |
| Middle           | 14        | 14.0    | 11        | 11.0    |
| Matric           | 21        | 21.0    | 21        | 21.0    |
| FA, SA           | 124       | 124.0   | 10        | 10.0    |
| P.A.S, A          | 11        | 11.0    | 9         | 11.0    |
| masters & above  | 0         | 0.0     | 4         | 4.0     |
| Total            | 100       | 100.0   | 100       | 100.0   |

Regarding the occupational status of the subjects, it was found that 26.0% were housewives, 22.0% were students and 20.0% were farmers. Among the respondent 35.0% were students, 19.0% were farmers/laborers and 18.0% were govt. employee/pvt. (Table No.: 4).

Table 4: Occupational statuses of subjects and respondents

| Occupation          | Occupation of subject | Occupation of respondent |
|---------------------|-----------------------|-------------------------|
|                     | Frequency | Percent | Frequency | Percent |
| Unemployed          | 15        | 15.0    | 12        | 12.0    |
| Farmer / Laborer    | 20        | 20.0    | 19        | 19.0    |
| Business            | 8         | 8.0     | 12        | 12.0    |
| Employee Govt. / Pvt.| 9        | 9.0     | 18        | 18.0    |
| Student             | 22        | 22.0    | 35        | 35.0    |
| Housewife           | 26        | 26.0    | 4         | 4.0     |
| Total               | 100       | 100.0   | 100       | 100.0   |

6.07% of subjects lived in urban areas and 33.0% lived in rural areas. (Graph No.: 2) Relationship of accompanying person was assessed and it was found that 42.0% were parents of subjects, 22.0% were...
40.0% of subject's symptoms where recognized in more than 2 years, 19.0% of subjects recognized symptoms within 1-2 years. 66.0% of subjects took psychiatric consultation in < 6 months, 13.0% of subjects took psychiatric consultation between 6 months to 2 years and 21.0% of subjects took psychiatric consultation for first time after two years (Table No. :6).

Table 6: Problem first recognized and Psychiatric consultations taken for first time:

| Duration | Problem first recognized | Psychiatric consultation taken for first time |
|----------|--------------------------|---------------------------------------------|
|          | Frequency | Percent | Frequency | Percent |
| < 6 months | 30 | 50.0 | 66 | 66.0 |
| 6 - 1 year | 11 | 11.0 | 6 | 5.0 |
| 1 - 2 years | 19 | 19.0 | 7 | 7.0 |
| 2 years | 40 | 40.0 | 21 | 21.0 |
| Total | 100 | 100.0 | 100 | 100.0 |

Regarding problem recognized first by whom and who convinced from treatment. 60.0% were the patients relatives who first recognized this problem, 36.0% of subjects themselves recognized their problem and sought for treatment. 4.0% subject's friend first recognized the symptoms. 68.0% subjects were convinced for treatment by their relatives, 21.0% themselves opted for treatment and 11.0% by their friends. (Table No.: 7).

Table 7: Problem recognized first by whom and who convinced for treatment

| Relation of respondents with subject | Problem recognized first by whom | Who convinced for treatment |
|-------------------------------------|---------------------------------|-----------------------------|
|                                    | Frequency | Percent | Frequency | Percent |
| Self | 26 | 36.0 | 21 | 21.0 |
| Relative | 60 | 60.0 | 68 | 68.0 |
| Friend | 4 | 4.0 | 11 | 11.0 |
| Total | 100 | 100.0 | 100 | 100.0 |

Consultation taken by respondents for subjects was also asked and it was found that 42.4% consultations were from GP, 19.9% from Pier, 12.0% from Religious Clerics and 10.5% from Hakim, Fakir and Malang accounted for 5.7% and only 2.6% consultants were taken from psychotherapist. When asked about the mode of treatment from the respondents, it was found that 44.4% of the subjects used drugs, 29.3% dum, 23.6% taweez and 3.1% used exorcism/violence as a treatment modality. (Table No.: 8 & 9).

Discussion

The World Health Organization noted that one in every four people is affected by a mental disorder at some stage of life (31). Six neuropsychiatry conditions, have figured in the top causes of disability in the world (32). in India, 2-5% of the population is suffering from serious mental illnesses, while another 10% of the population is suffering with minor mental illnesses(33-3). In India, there are a very small number of qualified psychiatrists (34). The non-availability of mental health services, penury, stigma, and superstitions associated with mental disorders, coupled with the unwillingness or
inability of families to care of their mentally ill relatives, appear to be the main contributory factors (35). The criterion used to assess the mental illnesses was William C Menninger criteria which showed that education had a significant association with health seeking behavior (p<0.05) and No. significant difference was found in health seeking behavior of males and females (p>0.05)(36). In our study 53.0% were females and 47.0% were males and 28.0% of subjects were illiterate, 21% had attended primary school and 14.0% had attended secondary school. Among the respondents 36.0% were illiterate, 21.0% had attended primary school and 10.0% attended secondary school. They likely influence the family’s help-seeking decisions and affect both adherence with biomedical interventions and social integration of the patients (37). Mean age of subjects were 31 years SD + 15.02, median age 27 and mode 18. Minimum ages of subjects were 10 years and maximum ages of subjects were 80 years. (Table No.: 1 & 2). 53.0% were females and 47.0% were males. Among the respondent 35.0% were students, 19.0% were farmers/laborers and 18.0% were govt. employee/pvt. (Table No.: 4). 6.07% of subjects lived in urban areas and 33.0% lived in rural areas.

In our study consultations taken by respondents for subjects was also asked and it was found that 42.4% consultations were from GP, 19.9% from Pir, 12.0% from Religious Clerk and 10.5% from Hakim, Fakir and Malang accounted for 5.7% and only 2.6% consultant were taken from psychotherapists. When asked about the mode of treatment from the respondents, it was found that 44.4% of the subjects used drugs, 29.3% dum, 23.6% taweez and 3.1% used exorcism/violence as a treatment modality(38).

Conclusion
The conclusion of our study is:
* There is a delay in recognition of psychiatric illnesses in our setting.
* Parents seem to be more concerned about taking treatment from psychiatric facility.
* Faith healers consultations are significantly sought in our community.
* Satisfaction level regarding allopathic treatment is more than spiritual healing practices.

Acknowledgements
We are deeply grateful to the Head of Department and allied staff of psychiatric department of Jinnah Hospital Lahore for their facilitation for data collection.
