Materials
Cadmium nitrate tetrahydrate (Cd(NO$_3$)$_2$·4H$_2$O, Fluka, ≥99%), sodium myristate (Na(myr), TCI, ≥98%), selenium (Se, Aldrich, 100 mesh, 99.99%), cadmium acetate dihydrate (Cd(OAc)$_2$·2H$_2$O, Fluka, ≥98%), oleic acid (OA, Aldrich, 90%), ammonium sulfide aqueous solution ((NH$_4$)$_2$S, Aldrich, 40-48%), oleylamine (OAm, Aldrich, 70%), 1-octadecene (ODE, Aldrich, 90%), N-methylformamide (MFA, TCI, >99%), formamide (FA, Aldrich, 99%), acetonitrile (ACN, Aldrich, ≥99.9%), toluene (Aldrich, ≥99.7%), hexane (Aldrich, ≥95%), ethanol (EtOH, Aldrich, ≥99.8%), methanol (MeOH, Aldrich, ≥99.9%), chloroform-d (CDCl$_3$, ≥99.8 atom% D), benzene-d$_6$ (C$_6$D$_6$, ≥99.5 atom% D).

Biradical polarizing agents: TEKPol$^1$ and AMUPol$^2$ were provided by Dr. Olivier Ouari, Dr. Gilles Casano and Prof. Dr. Paul Tordo (Aix-Marseille Université). Meso-SiO$_2$ matrices: 15 nm silica (Davisil Grade 643, Aldrich), 30 nm silica gel (spherical shapes, AlfaAesar).

Methods
Synthesis Protocols
Cadmium precursor synthesis. Cadmium myristate (Cd(myr)$_2$) was synthesized by dropwise addition of 3.085 g Cd(NO$_3$)$_2$ (10 mmol) in 100 mL MeOH to 7.51 g Na(myr) (30 mmol) in 1 L MeOH. Precipitated Cd(myr)$_2$ was filtrated, washed twice with MeOH and dried in a vacuum oven at 50°C for 16 h.

CdSe NPL synthesis. CdSe nanoplatelets (NPLs) with emission at 511 nm were synthesized as reported elsewhere,$^3$-$^4$ with slight modifications. 222 mg of Cd(myr)$_2$ (0.391 mmol), 15.7 mg of Se mesh (0.199 mmol) and 20 mL of ODE were degassed in a three-neck flask at room temperature for 30 min and heated up to 100 °C under vacuum. Then the flask was filled with argon and the mixture was quickly heated to 240 °C. When the temperature reached 190-195 °C, 52 mg of Cd(OAc)$_2$ (0.195 mmol) were introduced as a powder together with 1 mL of hexane (caution: hexane evaporates immediately!). The reaction mixture was kept at 235-240 °C for 5 min and then cooled down with air flow. When temperature dropped to 65-70 °C, 2.6 mL of OA and 3 mL of hexane were added and the mixture was stirred for additional 5 min. The obtained solution was transferred into centrifuge tubes together with 10 mL of hexane. The NPLs were separated by centrifugation at 12 krpm (19800×g) for 10 min. The supernatant was discarded while the precipitate, containing only NPLs, was redissolved in 1 mL hexane. This solution was additionally purified by diluting with 4 mL hexane, precipitating with 2.5 mL EtOH at 12 krpm, redispersing in 1 mL hexane and filtrating trough 0.45 μm polytetrafluoroethylene filter.

CdSe/CdS core/shell NPLs synthesis. CdSe/CdS core/shell NPLs were synthesized analogously to ref.$^5$ 15 mg of CdSe NPLs in 2.4 mL hexane (yellow solution) were combined with 3.6 mL of MFA and 36 μL of (NH$_4$)$_2$S aqueous solution (light-yellow solution) inside a vial. The biphasic system was heavily stirred under ambient conditions for ~3-5 min. After complete phase transfer (colorless hexane phase and orange MFA phase) NPLs in MFA were rinsed three times with 2 mL of fresh hexane and precipitated with 3.6 mL ACN and 5.8 mL toluene. One third of the precipitated NPLs (corresponding to ca. 5 mg of initial CdSe NPLs) was directly redissolved in 0.1 mL MFA (CdSe/S$^2$ in MFA sample). The rest (10 mg of initial CdSe NPLs) was redissolved in 1 mL MFA and mixed with 1.2 mL of 0.2 M Cd(Ac)$_2$ solution in MFA. After 1 min, NPLs were precipitated with 4.4 mL toluene. Half of this precipitate (corresponding to 5 mg of initial CdSe NPLs) was redissolved in 0.1 mL MFA (CdSe/S$^2$/Cd$^{2+}$MFA sample). The rest was redissolved in 0.28 mL hexane with 33.2 μL OAm, precipitated with 0.24 mL EtOH and redissolved in hexane (CdSe/CdS-OAm in hexane sample).
Computational Details
All geometry optimizations were performed with the Gaussian09 package at the PBE0 level. Cd and Te were represented by lanl2dz effective core potentials (ECP) and the associated basis set. H, O, S, and Se atoms were represented by a by triple-ζ-type basis sets. NMR calculations were performed within the GIAO framework using ADF 2014 with the PBE0 functional and Slater-type basis sets of quadruple-ζ quality (QZ4P) on Cd and triple-ζ quality (TZ2P) on all other atoms. Relativistic effects were treated by the two-component zeroth order regular approximation (ZORA).

Characterisation
UV/VIS/IR Absorption Spectroscopy
UV/VIS/IR absorption spectra were collected using a JASCO V670 spectrometer.

Photoluminescence Spectroscopy
A fluoromax-4 Horiba spectrofluorimeter equipped with a visible PMT detector was used to acquire the steady state photoluminescence (PL) spectra of NPL solutions. The excitation wavelength was 530 nm with a bandwidth of 1 nm.

Electrophoretic Mobility
Electrophoretic mobility was measured using a Zetasizer Nano-ZS (Malvern Instruments, Inc.). Colloidal solutions were measured using a dip-cell setup with Pd electrodes. Typical measurements of electrophoretic mobility included several scans of 100 runs each in the high-resolution mode. Dilution was optimized for each sample to achieve >100 kcps count rate and the best signal-to-noise ratio. The voltage applied to colloidal solutions was typically between 2 V and 10 V for polar solvents (MFA) and 40 V for nonpolar ones (chloroform). Table S1 summarises the zeta-potentials of the studied CdSe NPLs systems.

Table S1: Summary of the zeta-potentials of CdSe NPLs at different stages of CdS shell growth.

| NPL system                  | CdSe-OA | CdSe/S2- | CdSe/S2-/Cd2+ | CdSe/CdS-OAm |
|-----------------------------|---------|----------|---------------|--------------|
| Voltage (meV)               | 0       | -14      | +5            | 0            |

Transmission Electron Microscopy
Transmission electron microscopy (TEM) images were recorded on a JEOL JEM-2200FS microscope operated at 200 kV.

Solution-state NMR
Solution-state NMR spectra were acquired on a Bruker 11.7 T spectrometer equipped with a PABBO probe head for 5 mm NMR tubes and an Avance III console. Experiments were performed at room temperature without spinning the sample. During solution NMR experiments, the Waltz16 decoupling sequence was applied with a radio frequency (rf) field of 3 kHz. Chemical shifts were referenced to Si(CH3)4 (1H, 13C)

Detailed experimental conditions such as pulse sequence, pulse length, etc. are listed below in “Details about Displayed NMR Experiments”.

DNP NMR
DNP NMR experiments were conducted on a commercial Bruker 14.1 T DNP NMR spectrometer equipped with an Avance III console and triple or double resonance 3.2 nm low temperature MAS probe. The
microwave frequency of 395 GHz was generated by a Bruker gyrotron which output an approximate microwave power of 6 W.

Cross polarization (CP) transfer\textsuperscript{18} was conducted with variable amplitude during contact time.\textsuperscript{19} Delay times were set to be 1.3 times the $T_1$ obtained from saturation recovery experiments of the protons of the solvent. The SPINAL-64 hetero-nuclear decoupling sequence\textsuperscript{20} with a rf field of 100 kHz was used for all DNP NMR experiments. Chemical shifts were referenced to Si(CH$_3$)$_4$ ($^1$H, $^{13}$C), Cd(CH$_3$)$_2$ ($^{111}$/113Cd).

Detailed experimental conditions such as pulse sequence, spinning frequency of the MAS, pulse length, etc. are listed below in “Details about Displayed NMR Experiments”.
**Relation of the Chemical Shift and the Electronic Structure**

The dependence of the chemical shift of a semiconductor on its electronic structure, including its band gap, can be understood from theory.\textsuperscript{21} The experimentally observed chemical shift \( \delta \) is expressing the shielding tensor \( \sigma \) with respect to a reference compound (ref):

\[
\text{chemical shift tensor component: } \delta_{\alpha\beta} = \frac{\sigma_{\alpha\beta,\text{ref}} - \sigma_{\alpha\beta}}{1 - \sigma_{\alpha\beta}} \text{ where } \alpha,\beta,\gamma = \text{Cartesian axes} \quad (1)
\]

The shielding tensor can be separated into a diamagnetic (\( \sigma_d \)), a paramagnetic (\( \sigma_p \)) and spin-orbit (\( \sigma_{SO} \)) component:

\[
\sigma = \sigma_d + \sigma_p + \sigma_{SO} \quad (2)
\]

The diamagnetic contribution is defined as the shielding of the observed spin from the external magnetic field by the magnetic field induced by the molecular electronic ground state structure:

\[
\sigma_d = \frac{\mu_0}{4\pi} \frac{e^2}{2m_e} \langle \Psi_0 | \sum_i \alpha_i^2 + \beta_i^2 \frac{r_i^3}{r_i^3} | \Psi_0 \rangle \quad (3)
\]

It only depends on the ground electronic state \( \Psi_0 \), summing over \( i \) electrons. \( r_i \) is the distance between the nucleus and the electron \( i \) and \( \alpha_i/\beta_i \) are the distances of the electron \( i \) to the nucleus along the axes \( \alpha \) and \( \beta \). The factor \( r_i^3 \) induces a strong distance dependence of the diamagnetic shielding, whereby the nearest electrons, \( \alpha \) the ones of the core, have the biggest impact. The diamagnetic shielding is hence a mostly nucleus-specific shielding contribution and usually independent of the chemical environment of a spin.

The paramagnetic contribution to the shielding tensor of a spin results from the admixture of electronically excited states \( \Psi_j \) to the ground state \( \Psi_0 \) by action of the magnetic angular momentum operator \( \hat{l}_n \) of a spin \( n \). It can be well described in a 2\textsuperscript{nd} order perturbation approach:\textsuperscript{22}

\[
\sigma_{nm}^p = -\frac{\mu_0}{4\pi} \frac{e^2}{2m_e} \sum_{j \neq 0} \left[ \langle \Psi_0 | \sum_i \hat{l}_m \hat{l}_n | \Psi_j \rangle \langle \Psi_j | \sum_i \hat{l}_m \hat{l}_n | \Psi_0 \rangle + \langle \Psi_j | \sum_i \hat{l}_m \hat{l}_n | \Psi_0 \rangle \langle \Psi_0 | \sum_i \hat{l}_m \hat{l}_n | \Psi_j \rangle \right] \quad (4)
\]

In semiconductor materials, \( \Psi_0 \) represents the wave function of electrons in the valence band at the energy \( E_0 \) and \( \Psi_j \) represents the wave function of electrons in the conduction band at the energy \( E_j \). Consequently, \( E_j - E_0 \) is equivalent to the band gap energy, which eventually is inversely proportional to the chemical shift.

For heavy atoms, spin-orbit coupling significantly influences their shielding tensor and it has therefore to be included in the theoretical treatment of the chemical shielding. Spin-orbit coupling arises from the magnetic interaction of the electron spin angular momentum with the electron orbital angular momentum and is particularly strong in systems with heavy nuclei, where the velocity of electrons in the core region is high. The spin-orbit interaction can be treated by perturbation theory to third order, by a coupling of the singlet ground state with triplet excited states in combination with Fermi-contact and spin-dipole hyperfine interactions. This interaction leads to a deformation of the electron density as well as to a magnetically induced spin density, which influence the NMR chemical shift.\textsuperscript{23-24}

The totality of the DFT calculations performed for this work are listed in Table S2, S3 and S4.
Table S2. Comparison of the calculated total shielding and shielding contributions of the octahedral hexa-aqua cadmium complex [Cd(OH\(_2\))\(_6\)]\(^{2+}\) and the tetrahedral tetra-aqua cadmium complex [Cd(OH\(_2\))\(_4\)]\(^{2+}\). All shielding values are indicated in ppm.

| Shielding contribution | [Cd(OH\(_2\))\(_6\)]\(^{2+}\) | [Cd(OH\(_2\))\(_4\)]\(^{2+}\) |
|------------------------|-------------------------------|-------------------------------|
| total shielding \(\sigma_{iso}\) | 4314 | 4368 |
| diamagnetic contribution \(\sigma_{dia}\) | 4817 | 4819 |
| paramagnetic contribution \(\sigma_{para}\) | -1046 | -992 |
| spin-orbit contribution \(\sigma_{SO}\) | 543 | 541 |

Figure S2. $^2$H CP DNP NMR spectra evidencing the presence of acetate ligands at the CdSe NPL surface. (a) The $^2$H DNP NMR spectrum of conventional ZB CdSe NPLs capped with carboxylate ligands acquired at a spinning speed of 10 kHz. Naturally abundant $^2$H of the oleate/myristate is assumed to be responsible for the signal in (a) since $^2$H signal from the solvent (TCE) was reported to be very weak.\(^{25}\) If deuterated cadmium acetate (Cd(OAc-d\(^3\))\(_2\)) is used during the ZB CdSe NPL synthesis, no split signal is observed. Instead, a broad signal of a similar width is found (b). The difference between the two spectra (c) must correspond to the signal from deuterated acetate as the two synthetic procedures were identical except for the degree of deuteration of the cadmium acetate. The absence of free ligands was verified with liquid NMR, where no signal from free ligands was found (not shown). Neither was there a signal of free cadmium carboxylate around -680 ppm in the $^{113}$Cd DNP NMR spectrum (reference spectra of free Cd(OAc)\(_2\) in formamide (FA), MFA, DNP juice [60:30:10 (v/v) of glycerol-d\(^8\)/D\(_2\)O/H\(_2\)O], OAm and Cd(oleate)\(_2\) in TCE-ODE mixture are shown in Figure S5). Furthermore, acetate is insoluble in the apolar solvent in which the NPLs were solubilized, i.e. 1,1,2,2-tetrachloroethane (TCE). Therefore, we can conclude that the additional deuterium signal must originate from deuterated acetate OAc-d\(^3\) binding to the NPL’s surface.
Figure S3: $^{111/113}$Cd DNP NMR spectra of Cd(OAc)$_2$ in FA (-688 ppm, shoulder at -637 ppm), Cd(OAc)$_2$ DNP juice (-685 ppm), Cd(OH)$_2$ in FA (broad signal at -623 ppm from dissolved cadmium, sharp peak at -495 ppm from crystalline, non-dissolved Cd(OH)$_2$) and Cd(oleate)$_2$ in TCE/ODE (-694 ppm). $^{113}$Cd low-temperature spectrum of Cd(OAc)$_2$ in MFA (-693 ppm). DNP juice consists of 60:30:10 (v/v) of glycerol-d$_8$/D$_2$O/H$_2$O.
Figure S4: Graph displaying the linear trend when gradually exchanging SH$_2$ ligands with SeH$_2$ ligands in cadmium complexes with formula [Cd(SH$_2$)$_4$]$_{2-}$n(SeH$_2$)$_n$ where n = 0-4. The ligands coordinating to the cadmium atoms are indicated in the x-axis whereby S = SH$_2$ and Se = SeH$_2$. The raw data can be found in Table S3.
Figure S5: Formation of carbamate (blue, bottom) from OAm in CDCl$_3$ (black, top) was achieved by adding dry ice to the solution. The characteristic carbonyl peak is observed at 163 ppm (HCOO-NH$_2$-CH$_2$-). However, conversion is incomplete as in the heteroatom bound region of the spectrum not only carbamate signal is found (39 ppm, HCOO-NH$_2$-CH$_2$-) but also OAm signal (42 ppm, NH$_2$-CH$_2$-).
**Figure S6**: $^{13}$C solution (top, black) and DNP (bottom, blue) NMR spectra of core/shell CdSe/CdS-OAm NPLs. Due to slow tumbling of the NPLs, only the end of the aliphatic chain is visible in the solution spectrum, proving that the oleylamine is surface bound. The DNP spectrum displays the C=C double bond signal at 130 ppm. The absence of a carbonyl signal (180-185 ppm) and the absence of a carbamate signal (160-165 ppm) is indicating that no oleic acid nor carbamate is bound to the surface. However, the absence of carbonyl signal is not contradictory to the presence of acetate at the surface as the rotation of the methyl group might lead to the loss of carbonyl acetate signal by accelerated relaxation.$^{26-27}$
Details about Sideband Pattern Fit to Extract CSA Parameters

The chemical shift anisotropy (CSA) parameters of the species from the spectra presented in Figure 3 and listed in Table 1, were obtained by fitting the sideband patterns in the indirect dimension of the 2D PASS spectrum in their respective isotropic chemical shift region. The approximate probability distributions for each of the line shape parameters were determined using ordinary least square maximum likelihood estimation, utilizing a $\chi^2$ scaled Markov chain Monte Carlo method to sample the parameter space. Three different models were used to simulate the sideband order spectra. For sites without significant anisotropy, an upper bound on the strength of the anisotropy $|\Delta|$ was determined by modeling the line shape with a single CSA tensor subject to the constraint $\eta = 1$. The lower bound is assumed to be zero since this model is susceptible to overfitting noise riding the $k = \pm 1$ order sideband intensities. For the remaining sites, the sideband intensity profiles were modeled according to the $\Delta$ and $\eta$ parameters of a single CSA tensor. In two cases (CdSe/S$^2$- and the broad feature of CdSe/CdS-OLA), the sideband profile of the integrated isotropic region also contains a contribution from species without significant anisotropy; here, the CSA parameters of the significant contribution were estimated by assuming that $\Delta = 0$ for the site with small CSA. This was achieved by masking the centerband from the fit to the sideband profile. All ranges reported correspond to approximate 95% confidence regions. A ‘(±)’ symbol indicates that the sign of $\delta$ is ambiguous, which occurs when $\eta$ is predicted to be unity.

The fit results are summarized for all four stages of c-ALD (CdSe-OA, CdSe/S$^2$, CdSe/S/Cd and CdSe/CdS-OAm) in the figures below (Figure S7, Figure S8, Figure S9 and Figure S10).

**Figure S7.** Sideband patterns and fits thereof of the core (a) and surface (b) species of olate-capped ZB CdSe NPLs. The CSA parameter values obtained from the fit are listed below the legends. The color code is the same as in Figure 3.
Figure S8. Sideband pattern and fit thereof of the core species of sulfide-capped CdSe NPLs in MFA. The CSA parameter values obtained from the fit are listed below the legend. The color code is the same as in Figure 3.

Figure S9. Sideband patterns and fits thereof of free Cd(OAc)$_2$ (a), naked surface Cd (b), surface Cd-acetate (c), core CdSe (d) and core CdS (e) in CdSe/S$_2$/Cd$^{2+}$ colloidal NPL solutions in MFA. The CSA parameter values obtained from the fits are listed below the legends. The color code is the same as in Figure 3.
Figure S10. Sideband patterns and fits thereof of the core (a) and surface (b) species of oleylamine-capped CdSe/CdS core/shell NPLs. The CSA parameter values obtained from the fit are listed below the legends. The color code is the same as in Figure 3.
Details about Displayed NMR Experiments

**Figure 1 and 3: CdSe-OA NPLs in hexane**

Approximately 3 mg of ZB CdSe-OA NPLs in 1,1,2,2-tetrachloroethane (TCE, 12.7 µL) were mixed with 6.3 µL 50 mM TEKPol in TCE on a watch glass yielding a final TEKPol concentration of 16 mM. Minimal amount of meso-SiO₂ (30 nm pore size) was impregnated with the radical-QD solution and then packed into a 3.2 mm sapphire rotor.

**Acquisition parameters for $^{113}$Cd DNP enhanced PASS-PIETA**

| Parameter                                         | Value          |
|---------------------------------------------------|----------------|
| Magnetic field                                    | 14.1 T         |
| Temperature                                       | 100 K          |
| Rotor diameter (mm)                               | 3.2            |
| Pulse Sequence                                    | CP-PASS-PIETA  |
| Number of scans                                   | 18             |
| Recycle delay (s)                                 | 6.8            |
| Spectral width (kHz)                              | 625            |
| Spinning frequency (Hz)                           | 10000          |
| Acquisition length (number of points)             | 1220           |
| $^1$H 90° pulse width $[^\pi/2]$ (µs)              | 2.5            |
| Contact pulse length (ms)                         | 14.0           |
| $^1$H rf field during contact pulse (kHz)         | 100            |
| $^{113}$Cd rf field during contact pulse (kHz)    | 63             |
| $^{113}$Cd 90° pulse width $[^\pi/2]$ (µs)        | 3.2            |
| Number of pass steps                              | 12             |
| Number of echos                                   | 40             |
| Number of phases                                  | 48             |

**Figure 3: CdSe/S²⁻ in MFA**

Approximately 2.5 mg of CdSe/S²⁻ NPLs in MFA (50 µL) were impregnated with meso-SiO₂ (30 nm pore size) and washed twice with 1.5 mL fresh toluene in order to remove all MFA. The meso-SiO₂ was dried under vacuum until complete evaporation of the toluene. Finally, minimal amount of the CdSe-silica was impregnated with 20 µL 16 mM TEKPol solution in TCE and packed into a 3.2 mm sapphire rotor.

**Acquisition parameters for $^{113}$Cd DNP enhanced PASS-PIETA**

| Parameter                                         | Value          |

| Spinning frequency (Hz)                  | 0                          |
| Acquisition length (number of points)    | 297616                     |
| $^{13}$C 90° pulse width [$\pi/2$] (µs)  | 9.5                        |

Figure S5: oleylamine saturated with CO$_2$

One drop of as-purchased oleylamine was diluted in 400 µL CDCl$_3$ and several grams of dry ice were added to the solution. Before starting the NMR measurement complete sublimation of the CO$_2$ was awaited.

Acquisition parameters for $^{13}$C solution NMR

| Parameter                                | Value                      |
|------------------------------------------|----------------------------|
| Magnetic field                           | 11.7 T                     |
| Temperature                              | 298 K                      |
| Tube diameter (mm)                       | 5                          |
| Pulse Sequence                           | zgpg30                     |
Oleylamine-capped core/shell CdSe/CdS NPLs were dissolved in tetrachloroethylene and a sealed capillary containing C₆D₆ was added into the NMR tube for locking the NMR signal.

**Acquisition parameters for ³¹C-{¹H} solution NMR**

| Parameter                                      | Value         |
|------------------------------------------------|---------------|
| Magnetic field                                 | 11.7 T        |
| Temperature                                    | 298 K         |
| Tube diameter (mm)                             | 5             |
| Pulse Sequence                                 | zgpg30        |
| Number of scans                                | 8192          |
| Recycle delay (s)                              | 2.0           |
| Spectral width (kHz)                           | 30            |
| Spinning frequency (Hz)                        | 0             |
| Acquisition length (number of points)          | 297616        |
| ³¹C 90° pulse width [π/2] (µs)                  | 9.5           |

**Figure S6: Core/shell CdSe/CdS-OAm NPLs in hexane**

Core/shell CdSe/CdS-OAm NPLs in TCE (12.7 µL) were mixed with 6.3 µL 50 mM TEKPol in TCE on a watch glass yielding a final TEKPol concentration of 16 mM. Minimal amount of meso-SiO₂ (30 nm pore size) was impregnated with the radical-NPL solution and then packed into a 3.2 mm sapphire rotor.

**Acquisition parameters for ¹³C DNP NMR**

| Parameter                                      | Value         |
|------------------------------------------------|---------------|
| Magnetic field                                 | 14.1 T        |
| Temperature                                    | 100 K         |
| Rotor diameter (mm)                            | 3.2           |
| Pulse Sequence                                 | CP-echo       |
| Number of scans                                | 1024          |
| Recycle delay (s)                              | 10.0          |
| Spectral width (kHz)                           | 385           |
| Spinning frequency (Hz)                        | 10000         |
| Acquisition length (number of points)          | 9326          |
| ¹H 90° pulse width [π/2] (µs)                   | 2.8           |
| Contact pulse length (ms)                      | 7.0           |
| ¹H rf field during contact pulse (kHz)         | 84            |
| ¹¹³Cd rf field during contact pulse (kHz)      | 15            |
| ¹¹³Cd 180° pulse width [π] (µs)                 | 11.8          |
